summed up the evidence against the use of alcohol as follows:—1. Alcohol was not necessary to health. 2. It was of no importance as a food. 3. It did not sustain the bodily heat. 4. It was prejudicial to hard work. 5. To children it was especially injurious. 6. It lessened the duration of life and increased the liability to disease. It was for the profession to give the public a definite opinion on this subject, and thus to throw upon them all responsibility for the use of alcoholic beverages. The debate which followed was shared in by a great many gentlemen. Dr. Long Fox said that undoubtedly alcohol did good—within the limit of physiological safety—in aiding digestion; but the physiological limit should never be crossed, and the abuse of alcohol should always be spoken of in grave terms. Dr. Shingleton Smith would negative the question propounded, as the result of bringing the matter before the public would be to divide medical men in the eyes of the public into two groups—abstainers and non-abstainers. Physiologically, alcohol in moderation must be regarded as a food. Dr. Steele said the profession should be unanimous on the question, and agreed with Sir H. Thompson that alcohol was a luxury and not a necessity. Mr. Dobson held that alcohol in moderation was not prejudicial, and he regarded it as a food. Dr. Markham Skerritt argued powerfully on the affirmative side. He claimed accuracy for the statistics of temperance institutions, which clearly showed the advantages of abstinence over moderation. He quoted the opinion of Mr. Gardiner, surgeon to the Bristol Prison, who in an experience of fourteen years had never detected any ill effects from sudden abstinence. Dr. Parkes had shown that alcohol was worse than useless in all conditions of special exposure. The question of alcohol being a food was not to be met on narrow physiological grounds; but was it of such value that it must be used in spite of all the misery and crime that it caused? Other foods were used in excess, but their ill effects were utterly insignificant in comparison. The object of the profession should be to train up the rising generation as abstainers. Alcohol in strict moderation could not be said to be absolutely injurious; but to those in average health it was unnecessary, and the sum total of any value it might have as food was utterly insignificant in comparison with the sum total of evil it produced. Dr. Stewart spoke in the same sense. There were several other speakers, but space does not permit of our giving their arguments—some being in favour, but the majority in opposition to the line taken by the opener of the debate. Dr. Brittain concurred in Dr. Skerritt's observation about training the rising generation to do without alcohol. It was a food, and was useful as an aid to digestion; but if it came to be a question of moral responsibility, the evidence against its use was so strong that he thought he should be almost compelled to support abstinence. Dr. Ridge, in reply, said that the value of statistics was that they stated facts independently of the bias of opinion. That a substance was destroyed in the body was not sufficient evidence that it was a food—e.g., chloroform and turpentine were thus destroyed, but they were not therefore held to be foods. Alcohol and the other narcotics should be avoided by healthy people; but all *liked* them, and hence their use. The proceedings closed with a vote of thanks to the opener and the chairman.

THE SERVICES.

DEATHS OF ARMY MEDICAL OFFICERS.

We have to report the death, on the 29th August, at Belize, Honduras, in the West Indies, of Surgeon-Major Alexander Thomson, M.D. Dr. Thomson's death was very sudden, he having been in his usual health, and doing his duty till a few days before the fatal occurrence. Dr. Thomson entered the army in June, 1859, and was promoted Surgeon-Major in February, 1875.

The death of Surgeon-Major William Lougheed, Army Medical Department, is announced as having taken place at Peshawur, East Indies, on the 24th September, from heat-apoplexy. Mr. Lougheed obtained his first commission in October, 1866, and was promoted to the rank of Surgeon-Major in October, 1878.

VOLUNTEER AMBULANCE DEPARTMENT.

The class of volunteers belonging to the Tower Hamlets Rifles, who have undergone a course of instruction in

"stretcher drill" by the regimental surgeon, Dr. W. H. Platt, was inspected by Surgeon-General A. Shelton, Army Medical Department, the President of the Society, at the headquarters in Shaftesbury-street, on Monday last. The class consisted of twenty-four men, who have all obtained certificates of proficiency in stretcher drill, and the application of first dressings to the wounded. Dr. Shelton expressed himself much pleased with the steadiness of the drill, and the intelligence and aptitude displayed by the volunteers in their ambulance work.

Surgeon-Major John Anderson, medical officer on the Staff of the Viceroy of India, has arrived in England, and will accompany H.E. the Marchioness of Ripon to India on the 3rd November. Surgeon-Major H. Skey Muir officiates on Lord Ripon's staff during Mr. Anderson's absence.

Sir William Muir, K.C.B., Director-General of the Army Medical Department, has joined the council of the Army Coffee Tavern Society. We trust medical officers of the army and navy will give a hearty support to this very excellent movement.

Deputy Surgeon-General J. L. Jameson, being supernumerary to the Establishment of Administrative Officers in India, has been ordered to England, and is on passage in H.M. troopship *Himalaya*.

ADMIRALTY.—The following appointments have made made:—Staff-Surgeon Robert Walter Biddulph to the *Excellent*, in lieu of a surgeon; William J. Gibson to be surgeon and agent at Clontarf.

Deputy Inspector-General Henry Fagan, M.D., C.B., of the Royal Marine Division, Portsmouth, has been appointed to Jamaica Hospital.

MILITIA MEDICAL DEPARTMENT. — Surgeon-Major William Scott, Scottish Borderers Militia, resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the regiment on his retirement.

Correspondence.

"Audi alteram partem."

THE SITUATION AT GUY'S.

To the Editor of THE LANCET.

SIR,—The tone of your last week's article about Guy's is such that I, for one, should not take notice of it did I not feel that the manner in which you have represented the outcome of our struggle upon the nursing question is calculated to do harm by conveying the impression to those at other institutions that we have allowed the aggressive attempts upon medical authority to succeed.

What was our position at Guy's previous to the contest that has occurred? The answer is readily given by referring to the manner in which the treasurer and matron acted upon the installation of the latter in office just a year ago. The treasurer then, and formerly, possessed autocratic power; and it is a matter of history how he exercised it without the staff having any official power to control. As far as we were concerned, and our position was handed down to us by our predecessors, the treasurer was our supreme ruler, and according to the traditions of the institution the president and governors occupied an unapproachable position, except through the treasurer.

You, Sir, who have not been in the contest, are little aware of the difficulties we have had to encounter. Our first communications were held with the treasurer, and finding we could get no redress we appealed to the governors. The governors, we were told to begin with, must support the treasurer; but, continuing the contest, a Committee of Governors was appointed to investigate and report upon the whole question, and it was through this committee that the first substantial advance was made by the governors to meet us in adjusting the difficulty. The proposition now laid before us was that two representatives of our staff should be invited to attend once a month, or oftener if necessary, the Taking-in Committee of Governors with the view of deliberating on any matters relating to the medical and nursing arrangements. This proposition was carefully discussed

amongst us, and it was generally felt that if we accepted the invitation simply to attend the committee we should be placing ourselves and the profession in a wrong position. The committee might hear what our representatives had to say and afterwards adopt an antagonistic mode of action.

Our subsequent consent to co-operate with the governors was based upon their declaration (proceedings of a Special General Court held at Guy's Hospital, 7th October, 1880) that the matron is "willing to submit herself obediently to the orders of the several physicians and surgeons in all matters directly affecting the treatment of any patient," and upon the reception of our two representatives as an integral part of the Sub-committee appointed to deliberate on matters relating to the medical and nursing arrangements of the hospital.

Now, Sir, was it wrong to accept such terms as are here set forth, and do we deserve the hard words and insinuations which you have so indiscriminately hurled upon us? We began with no recognised status in relation to the nursing administration, and we leave off with an official position upon a committee of governors. Such is the very machinery which has been put forward by the press as the model to be copied. It remains, of course, to be seen how it will work within the walls of Guy's, but to show that the committee in question has no imaginary power, it may be mentioned that a recent proposal of the matron and treasurer affecting one of the sisters was overruled, and the sister remains in her ward.

You seem to have taken fright at the announcement by the governors, that they must "record their resolution to maintain in its integrity the power to govern the hospital entrusted to them by law." There are many who think that it would have been wise if, whilst making the concessions they have done, which give to the Staff an administrative position it did not enjoy before, the governors had not thought it necessary to trumpet forth these grandiloquent words, which in reality mean nothing more than a declaration of their position as the supreme governing body, which no one has ever disputed they hold.

I am, Sir, your obedient servant,

Grosvenor-street, Oct. 27th, 1880.

F. W. PAVY.

* * The words at which we "have taken fright" (!) are not those quoted, but the next following words of the same sentence, which affirm that the arrangement set forth "must be accepted by the medical staff." This virtually made the withdrawal of the demand for the resignation of the seniors conditional on the staff accepting "in its integrity" the rule of the governors—a rule involving a system which the staff had declared to be "in every respect mischievous."—ED. L.

HYPODERMIC INJECTION OF MORPHIA IN CHOLERA AND CHOLERAIC DIARRHŒA.

To the Editor of THE LANCET.

SIR,—Let me thank Mr. MacDowall for his letter on this subject in THE LANCET for October 16th; for, although his conclusions as regards the value of this method of treatment in Asiatic cholera are opposed to mine with respect to choleraic diarrhœa, his letter will stir up interest abroad, and thus, to a certain extent, further the object I have in view, which is the extensive routine use of the method in choleraic diarrhœa and cholera Asiatica, not as a *last* resort, but as a *first* resort.

I have carefully looked through both vols. of THE LANCET for 1872, also for 1871 and 1873, but can find no reference to Mr. MacDowall's cases, though I found a notice of Surgeon-General Murray's report. But my disappointment as regards my primary object met with some compensation, for I unexpectedly came upon a most important communication from a Dr. Augustus Werry, of Constantinople, in which he states that he has used the hypodermic injection of morphia in twenty-two cases of true cholera with the most astonishing and brilliant success. His experience appears to have been, judging from his language, the exact counterpart of mine (*vide* THE LANCET, 1871, vol. ii. page 737).

Though I have called my cases "choleraic diarrhœa," many of them presented every symptom of Asiatic cholera so called, but I have avoided using the term "cholera" as having a conventional meaning, and being always intended to designate the Oriental disease; but I must admit that I

never have been able to perceive the slightest real difference between Asiatic cholera and bad English choleraic diarrhoea, and I have seen several cases of cholera in the last epidemic when a student at University College Hospital in London. Intense "præcordial anguish" was present in all my cases, and is a constant symptom in bad choleraic diarrhoea. I shall never forget the overpowering intensity of this symptom in a severe attack of choleraic diarrhoea I went through myself a few weeks after writing my paper.

Mr. MacDowall takes exception to my statement that "it is the purging that kills," inasmuch as many cholera patients die during reaction of a typhoid condition. This, of course, I am well aware of, and when first I commenced using the treatment, when it was a last resort, I nearly lost patients from this febrile condition; but as I consider that the danger and severity of this reaction are directly proportional to the amount of the purging, and caused by the purging, and not a subtle manifestation of the unexhausted action of the cholera poison, I must still adhere to my original statement that "it is the purging that kills." I would even go a step farther, and assert the seeming paradox that I believe in cholera it is the purging that kills and not the cholera poison.

I am obliged to Mr. MacDowall for his fair and friendly criticism of my views and cases, but he would place me under a still greater obligation if he would again try the treatment as a *first* resort, and publish the result.

I am, Sir, yours, &c.,

London, Oct. 21st, 1880.

WM. HARDMAN.

FARR TESTIMONIAL FUND.

To the Editor of THE LANCET.

SIR,—I am desired by the Committee charged with the promotion of the Farr Testimonial Fund to request that you will add to their obligations by publishing in your next issue the following further list of subscriptions.

Faithfully yours,

Oct. 26th, 1880.

NOEL A. HUMPHREYS, *Hon. Sec.*

Amount of Subscriptions already published, £925 2s.

As the Committee proposes shortly to close the subscription list, intending subscribers, who have not yet intimated their intention, are requested to communicate with the Hon. Sec., Mr. Noel A. Humphreys, General Register Office, Somerset House, London, W.C. All cheques or post-office orders should be crossed "Martin and Co."

A SUM amounting to £438 10s. 3d. has been handed over to the governors of the Lincoln County Hospital as the result of the Hospital Saturday movement.

Obituary.

DR. EDWARD ISAAC SPARKS.

THE death of this young physician, which took place on the 11th inst. at Crewkerne, in Dorsetshire, has robbed the profession of a man who, had he been endowed with physical qualities in any way commensurate with those of his mind, must have risen to the very foremost rank. He was the younger son of Mr. William Sparks, J.P., and was born at Crewkerne on September 25th, 1843. He received the rudiments of his education at the grammar-school of his native town, whence he was subsequently removed to Harrow, and ultimately entered Corpus Christi College, Oxford. At college his career was one of very great distinction. He graduated in 1866 with a first class in Natural Science, and second class honours in Classics. In 1868 he was appointed Radcliffe Travelling Fellow, and between this and 1871, in fulfilment of the conditions of the Fellowship, he travelled throughout Europe, visiting the chief medical schools in France, Germany, and Italy, and acquiring a sound knowledge of the three chief Continental languages. After graduating in Arts at Oxford he entered at University College, London, where he finished his medical education, graduating as M.B. in 1870, and taking the diploma of M.R.C.P. in 1872.

When Dr. Sparks settled in London in 1872 he had a right to be considered as one of the most highly educated members of the profession. Ancient and modern languages, the natural sciences, and the most advanced views on medicine, both of England and the Continent, he had made his own. But he was not a man to be led exclusively by the views and dogmas of others, and we accordingly find him eagerly seeking for opportunities of clinical study in the rich field afforded by our great metropolis. He became physician to the Mount-street Dispensary, the Children's Dispensary in Bell-street, and also to the Royal Hospital for Children and Women in the Waterloo-road. In 1874 he was made physician to the skin department at Charing-cross Hospital, and also subsequently had charge of a clinic for diseases of the throat.

This excessive devotion to the most unwholesome department of medical practice—viz., the out-patient practice of hospitals and dispensaries, soon told upon a constitution which was always feeble. In 1875 unmistakable signs of phthisis became manifest, and Dr. Sparks, who had only shortly before been married, found himself compelled to leave London for the south of France. His intention was to practise at Mentone, but at the outset his views were frustrated by the French regulation with regard to foreign practitioners. He was not a man to yield easily to obstacles, and accordingly in May, 1877, he qualified as an officier de santé at Marseilles, and began to practise systematically at Mentone. In the same year he published an English translation of Binz's Elements of Therapeutics, a work which was well received. From time to time Dr. Sparks published various papers on skin diseases, and notably a paper on "A Disease produced by the *Acarus folliculorum*," which appeared in the Medico-Chirurgical Transactions for 1874. After settling in Mentone, Dr. Sparks continued to suffer at intervals from lung trouble and also from profuse hæmaturia and albuminuria, but his bodily condition in no way dismayed him. He foresaw the result clearly enough, and contemplated his approaching end with a calmness which was little short of sublime. In the sixty-second volume of the Medico-Chirurgical Transactions he published, in connexion with his friend, Dr. Mitchell Bruce, a paper on the effect of diet, rest, and exercise in chronic nephritis, and the value of the paper and the respect for the author will alike be increased when it is known that he found the materials for the work in his own condition, and that, in fact, all the observations recorded in the paper in question were made upon himself.

Last year Dr. Sparks published a book upon the Riviera, which we reviewed most favourably in August last, and we have no doubt that it will prove a valuable work of reference.

It is needless to add that Dr. Sparks possessed a most unusual amount of energy combined with great scientific acumen. The catalogue of his writings and a record of their reception by the profession are a sufficient evidence of that.

In society Dr. Sparks was ever cheerful, and his highly cultivated mind and his great appreciation both of nature and of art made him one of the most agreeable of companions. Dr. Sparks was married in 1874, but has left no family.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

At a quarterly meeting of the Council on the 21st inst., the following gentleman, having been elected a Fellow at a previous meeting, was admitted as such, his diploma of Membership bearing date Dec. 2nd, 1842:—

King, Jasper Rumball, L.S.A., M.I.Ksham, Wilts.

At the same meeting of the Council, the following gentleman (Assistant-Surgeon to University College Hospital) was elected an *ad eundem* Fellow:—

Barker, Arthur Edward James, F.R.C.S. Irel. (1876).

The following gentlemen passed the required examination, and received the diploma in dental surgery, at a meeting of the Board of Examiners, on the 27th inst.:—

Carnock, George Dennis, Cable-street, E.
Hindley, Henry Newton, Alfred-place, Bedford-square.
Palmer, Thomas Frederick Barton, Peterborough.
Robbins, Cornelius, Epsom.
Worfor, Thos. Walter Cromptley, London-st., Fitzroy-sq.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 21st:—

Day, Donald Douglas, Blackheath.
Garrard, Chas. Rowland Ordish, Tickenhall, Derby.
Pryn, William Wenmouth, Tredown, Saltash.
Whitcombe, Charles Henry, New Zealand.

The following gentlemen also on the same day passed their Primary Professional Examination:—

James Donald, Charing-cross Hospital Charles Henry Piesse, King's College Hospital.

COLLEGE OF PHYSICIANS IN IRELAND.—At examinations held during October the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—George Henry Butler, John Edw. James Deane, Harry Chalmers Hudson, John Hugh Jones, Francis Joseph Lambkin, John Murphy, Edw. Connell Adair Ramsay, Henry Geo. Swain.
MIDWIFERY.—Harry Chalmers Hudson, John Hugh Jones, John Murphy, Henry George Swain, Edmond Wall.

Also the undermentioned Licentiates have been admitted Members:—

Daniel Patterson Barry, John King Forrest, Francis M. Harricks, George William Hatchell, Alexander Richard Joyce, George Kell, Henry Anthony Wills Richardson, Francis Patrick Staples, Peter O'Reilly, Eliza Louisa Walker Dunbar.

QUEEN'S UNIVERSITY IN IRELAND.—The following degrees and diplomas were conferred on the 13th inst. by His Grace the Duke of Leinster, Chancellor of the University:—

DOCTOR IN MEDICINE.—First Honour Class: Jeremiah Cotter, David M'Keown, John C. Bodkin, Hugh Brosnan, R. J. Hackett, Robert Thomas M'Geagh, Robert Shore, George James Haslam.—Upper Pass Division: Joseph Anderson, John Shiel Collins, John A. Cunningham, Robert J. Hamill, James Paul M'Geagh, Matthew M'Vickar, Adam A. C. Mathers, William Roulston, Albert M'Carthy Scully, Hugh Thomas Shaw, Samuel Hamilton Shaw, John Wallace Watson.—Lower Pass Division: Robert Alexander, John Howard Batty, Wm. Hamilton Caldwell, Richard Campbell, Henry Castles, George J. Coates, William R. Cole, William N. Davies, John J. Dinnis, David S. Dunn, S. Eakin, William Gordon Hanna, Robert Lynn Heard, Arthur Hickman, Edward Horan, William Kelly, T. M'Iroy, John M'Loughlin, Daniel Lehan, Samson Matthews, William J. Matthews, Lowry D. Morrell, W. D. Moore, William T. Mullally, Patrick Mullane, James Mullin, John F. L. Mullin, P. J. Nealon, Thomas Nunan, James A. Oakshott, Menus W. O'Keefe, Samuel James Parkhill, Thomas Pritchard, Robert Reid Rentoul, Jas. John Riordan, Robt. John Roulston, Simpson Stuart, Samuel Townsend, Edmond Wall, Charles Wells, Charles Wenyon, James Blair White, James F. White, James Whitton.

MASTER IN SURGERY.—Myles H. C. Atkinson, John C. Bodkin, Hugh Brosnan, William Hamilton Caldwell, George J. Coates, William R. Cole, J. T. Collier, Jeremiah Cotter, John A. Cunningham, James Davidson, John J. Dinnis, Samuel Eakin, R. J. Dalbey Hackett, Charles Hall, John Hosford, Charles Frederick Knight, James Paul M'Geagh, Robert Thomas M'Geagh, David M'Keown, Matthew M'Vickar, John Martin, Adam A. C. Mathers, Wm. David Moore, William T. Mullally, P. Mullane, Patrick Joseph Nealon, Thomas Nunan, Menus W. O'Keefe, Myles William O'Reilly, Samuel J. Parkhill, Jas. John Riordan, Robt. John Roulston, Wm. Roulston, Albert M'Carthy Scully, Hugh Thomas Shaw, Samuel H. Shaw, William Smyth, William Stokes, Samuel Townsend, Edmond Wall, Charles Wenyon, John Wilson, Ralph Worrall.

DIPLOMA IN MIDWIFERY.—Robert Alexander, Joseph Anderson, John C. Bodkin, Hugh Brosnan, William H. Caldwell, George J. Coates, John Shiel Collins, Jeremiah Cotter, Jas. Davidson, David

Simpson Dunn, Samuel Eakin, James Paul M'Geagh, Robert Thos. M'Geagh, Matthew M'Vickar, Adam A. C. Mathers, Patrick Mullane, Menus W. O'Keefe, Robert John Roulston, William Roulston, Albert M'Carthy Scully, Hugh Thos. Shaw, Samuel Hamilton Shaw, William Stokes, James Whitton.

JOHN CHURCHILL, M.R.C.S., has been placed on the Commission of the Peace for Cumberland.

MR. OTTO JACKSON KAUFFMANN has obtained the Dauntsey Medical Entrance Scholarship of £100 at Owens College.

A **BAZAAR** has been held in Llanelly in aid of the funds of the hospital of the town. The proceeds are expected to realise some £300.

MR. G. BULLOCK, of East Coker, has presented to the Yeovil Hospital a field—two acres, one rood, thirty-eight perches in extent.

By order of the Queen parcels of cast-off linen from the Royal Household have been forwarded to the London and the University College Hospitals.

The salary of **W. W. Coltart, L.R.C.P. Lond., M.R.C.S. Eng.**, Medical Officer to the Workhouse of the Epsom Union, has been increased from £50 to £75 per annum.

The Committee of the Aberdeen Royal Infirmary have recommended that in future the appointments of house-physician and house-surgeon should be held only by regularly qualified men, instead of, as at present, by third-year's students.

DR. FAUSSETT, OF CLONTARF.—Last week a resolution recently passed granting this gentleman a retiring allowance of £50 per annum, after forty-three years' service as medical officer, was rescinded; and notice of another motion has been given that the superannuation be fixed at £106 per annum.

MEDICAL SOCIETY, COLLEGE OF PHYSICIANS IN IRELAND.—An election for council, honorary secretary, and treasurer takes place this week. Dr. Duffey having resigned as honorary secretary and Dr. MacSwiney as treasurer, the duties will most probably be undertaken by Dr. Alexander Montgomery, who has been nominated for office.

ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.—Owing to the increased cost of living, together with the improved dietary of this hospital, and the loss sustained by the scale at present charged for the support of union patients, it has been determined for the future that the rate be increased from 1s. to 1s. 4d. per head per diem for all patients admitted after the 1st proximo.

PHARMACEUTICAL SOCIETY OF IRELAND.—On the 4th inst. the fifth annual meeting took place at the College of Physicians for election of office-bearers. The following constitute the new Council:—President: C. Tichborne. Vice-President: Aquila Smith. Members: William Allen, H. Bennett, J. Brunner, A. Doran, T. Collins, J. Goodwin, W. Goulding, G. Grindley, W. Harrington, W. Hayes, E. Hodgson, J. Holmes, S. Oldham, G. Owens, J. Payne, R. Pring, J. Ryan, R. Simpson, H. Whitaker. Treasurer: E. Hodgson. Registrar: Hugh Fennell.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BATTERBURY, R. L., M.B., has been appointed Medical Examiner of Recruits for the Regular Army and Militia, at Berkhamsted.

BEACH, F., M.B., M.R.C.S.E., has been appointed Medical Superintendent for the Asylum for Children at Darenth.

BURTON, A. H., B.A., M.B., M.R.C.S.E., has been appointed a Clinical Assistant to the Central London Throat and Ear Hospital, Gray's-inn-road.

FARKSTEIN, H., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Newington District of the Sculcoates Union.

HEATH, H. T., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer to the Second District of the Mansfield Union.

HUGHES, T. H., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Pwllheli District and the Workhouse of the Pwllheli Union, vice H. H. Hughes, deceased.

HUNT, T., M.D., has been appointed a Clinical Assistant to the Central London Throat and Ear Hospital, Gray's-inn-road.

JACKSON, G., L.R.C.P.L., F.R.C.S.E., has been appointed an Honorary Surgeon to the Plymouth Public Dispensary.

JESSOP, W. H., M.R.C.S.E., has been appointed House-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Mr. F. M. Pope, whose appointment has expired.

KEELAN, P., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Monasterboice Dispensary District of the Drogheda Union.

KEIR, W. I., L.R.C.P.Ed., has been appointed Medical Officer of Health to the Melksham Rural Sanitary Authority.

MOORE, W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Lower Milton District of the Kidderminster Union, vice Ormsby, resigned.

MUDGE, J., jun., L.R.C.P.Ed., has been appointed Medical Officer and Public Vaccinator to the No. 4 District of the Penzance Union, vice Trezise.

NELSON, T., M.B., C.M., has been appointed Resident Surgeon at the Birmingham Dispensary.

OATES, J. P., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Bampton District of the Witney Union.

ORAM, A. M., M.B., has been appointed a Clinical Assistant to the Central London Throat and Ear Hospital, Gray's-inn-road.

PINCK, W., M.B., C.M., L.R.C.S., has been appointed Medical Officer to Rochdale Workhouse and the Wardleworth District of the Rochdale Union, vice Collingwood, resigned.

RIDDELL, R., M.D., C.M., has been appointed Medical Officer to the Dunsford District of the St. Thomas Union.

STEPHENS, W. B., M.R.C.S.E., L.S.A.L., has been appointed Consulting Surgeon to the Plymouth Public Dispensary.

STEWART, W. R. H., F.R.C.S.Ed. &c., has been appointed a Surgeon to the North-West London Hospital.

TURNER, G., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer of Health to the Hertford, Ware, Buntingford, and Bishop's Stortford Rural Sanitary Authorities, and to the Bishop's Stortford Urban Sanitary Authority, vice Ogle, resigned.

TWEDDELL, G., M.R.C.S.E., L.S.A.L., has been elected Medical Officer of Health for the Northern Division of the Houghton-le-Spring Rural Sanitary District, vice Lyon.

WILLIS, J., L.R.C.P.Ed., M.R.C.S.E., has been appointed a Medical Officer to the Kilburn, Maida-vale, and St. John's-wood General Dispensary.

Births, Marriages, and Deaths.

BIRTHS.

BRADSHAW.—On the 24th inst., at Welbeck-street, the wife of Dr. Watson Bradshaw, formerly Staff-Surgeon, Her Majesty's Royal Navy, of a son.

HITCHCOCK.—On the 20th inst., at Market Lavington, the wife of C. K. Hitchcock, M.A., M.D. Cantab., Medical Superintendent, Kingsdown House Asylum, Box, Wilts, of a son.

LEEDS.—On the 22nd inst., at Ramsgate, the wife of E. Leeds, M.B., of a son.

MURPHY.—On the 12th ult., at Kamptee, C.P., the wife of Surgeon F. H. S. Murphy, M.D., A.M.D., of a daughter, stillborn.

PRESTON.—On the 11th ult., at Amberley, Canterbury, New Zealand, the wife of Alfred Chevallier Preston, M.R.C.S.E., of a daughter.

ROPE.—On the 23rd inst., at the Gateway House, Shrewsbury, the wife of H. J. Rope, F.R.C.S., of a son.

WOODS.—On the 19th inst., at Alverstoke, Hants, the wife of Staff-Surgeon Henry C. Woods, M.D., R.N., of a son.

MARRIAGES.

JOLLY—BALDWIN.—On the 21st inst., at the Parish Church, King's Norton, Robert Jolly, M.D., of Edgbaston, Birmingham, to Fanny, only daughter of Joseph B. Baldwin, Esq., of Broad Meadow, King's Norton, Worcestershire.

WARDLE—HUTCHINSON.—On the 21st inst., at St. Andrew's, Auckland, Mark A. Wardle, L.R.C.P.Ed., L.R.C.S.Ed., to Jane E. M., third daughter of V. Hutchinson, M.D., of The Elms, Bishop Auckland.

WHITE—JENNINGS.—On the 21st inst., at The Abbey, Malmesbury, by the Rev. G. W. Tucker, M.A., the Vicar, assisted by the Rev. C. D. Forbes, B.A., Edward Arthur White, M.D., of Malmesbury, third son of Richard White, of Heathfield House, Norwich, to Anne Maude, only daughter of Joseph C. S. Jennings, F.R.C.S., of The Abbey House, Malmesbury, Wilts. No cards.

DEATHS.

ASPLAND.—On the 24th inst., at his residence, St. Helen's Field, Alfred Aspland, F.R.C.S., of Dukinfield, in his 65th year.

CROSBIE.—On the 16th inst., at Haslar Hospital, Gosport, Alexander Crosbie, M.D., Staff-Surgeon, R.N.

HEARNE.—On the 22nd inst., at Southampton, of apoplexy, Edwin Hearne, M.B., F.R.C.S.E., aged 60.

HORNBSBY.—On the 21st inst., at High-street, Bromsgrove, Worcester-shire, George Harcourt Hornsby, M.R.C.S.E., in his 28th year.

INGHAM.—On the 24th inst., at Ash Mount, Haworth, Yorks, Mary, the beloved wife of Amos Ingham, M.D., aged 52.

LEWIS.—On the 10th inst., at Brechia, Carmarthen, D. H. Lewis, L.S.A.L., aged 29.

LYNCH.—On the 22nd inst., at her residence, Commercial-road East, Mary Ann, the beloved wife of John Lynch, L.S.A.L., aged 59. R.I.P.

NORTH.—On the 20th inst., at Egremont, Cumberland, through a fall from his horse, Henry North, M.R.C.S.E., aged 30.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

DIETETIC VALUE OF FLESH FOOD.

Halifax.—The question in the form it is put is a difficult one to answer, much depending on the feeding, age, or whether the animal is in the wild or tame state. The flesh of wild animals contains proportionately more of the albuminous constituents and extractive matters than that of an animal kept in confinement. On the other hand, the fibre would be tougher, and not so much nutriment would be extracted from it by the digestive process as would be the case with a stall-fed animal. Moreover, the delicate blending of fat with the meat, which is found in the highest perfection in well-fed ox or heifer beef, is most favourable towards the promotion of perfect nutrition. The flesh of rabbits is poor in the fatty elements, and is consequently dry and unpalatable unless cooked with some fatty substance, as milk or bacon.

Mr. B. Htjer.—The question has been frequently raised. Probably information of what has been done in the matter may be obtained of the Secretary of the Ladies' Sanitary Association, 22, Berners-street, W. The letter of *Dr. De Renzy* will appear in our next.

A RARE OCCURRENCE FOLLOWING AN INJURY TO THE OUTER SIDE OF THE ORBIT.

To the Editor of THE LANCET.

SIR,—The following case may be of some interest to the readers of THE LANCET as an accident of an uncommon nature, and I see no allusion is made to such a condition in a recent work of Lawson on Diseases and Injuries of the Eye:—

Whilst acting for the divisional surgeon to the H Division of the Metropolitan Police, I was sent for to see a child with a cut eye. The constable who found the child said the mother, who was drunk, allowed it, a girl three and a half years old, to fall through a window. I found an incised wound on the outer and upper part of the orbit, about a quarter of an inch in length, and from this a fatty-looking, pyriform lump projected, which I ascertained was due to a complete hernia of the lachrymal gland, and this was hanging by a slender pedicle composed of the duct and vessels. As the patient was at a police station, where I should only see the case once, I put on some lint, and sent the child to a hospital, after applying taxis and failing to reduce it, so small was the opening through which it had protruded. There were some swelling and ptosis of the upper lid; but the globe of the eye was uninjured. The treatment of such a condition in so young a subject, had it remained under my care, would have been—firstly, an attempt to replace it by enlarging the incision, and then endeavouring to keep it in place by means of sutures; secondly, failing this, there would have been no other alternative but to excise the gland, and this I should have been disposed to do after first applying a ligature. The prognosis in such a case, I apprehend, would be of an unfavourable nature as to the sight of the eye being retained unimpaired; yet I am aware that the gland has been removed for the radical cure of lachrymal disease, but I think with unsatisfactory results so far as the eye is concerned.

Yours truly,

Spital-square, E., October, 1880.

C. E. WALKER, M.B. Edin.

A RARE CAUSE OF CONVULSIONS.

DR. BEARD, of New York, to whose investigations we are indebted for the discovery that nervous weakness is a new disease, has recorded, in his work on "Neurasthenia," that during a conversation about the disease with a medical friend, the orbicularis palpebrarum of the latter began suddenly to twitch—a phenomenon before unknown in the subjective experience of the individual. We fear that the investigation of diseases of the nervous system is having a deleterious effect on Dr. Beard's own well-being. At least such is the only conclusion we can form from the title of a recent paper, as it is announced in the usually exact *Jahresbericht* of Virchow and Hirsch. The announcement runs as follows:—"Beard, G. M. Convulsions from the study of one hundred and twenty-five cases of writers' cramp, and allied affections"!

Enquirer.—23, Bloomsbury-square, W.C.

THE TREATMENT OF HÆMORRHOIDS: CRUSHING VERSUS CLAMP AND CAUTERY.

To the Editor of THE LANCET.

SIR,—After reading Mr. Pollock's account of the treatment of hæmorrhoids by crushing in THE LANCET of July 3rd, I must say that I feel much more convinced of the superiority of the method by clamp and cautery as performed by Mr. Henry Smith, of King's College Hospital, and I am led to this conclusion on taking the following points into consideration:—

1. *The length of time taken to perform the operation.*—This, of course, is not of much moment when the patient is unconscious; but when such is not the case, the more quickly the operation is performed the better. And here I believe it will be found that the clamp and cautery will answer our purpose better than crushing; for Mr. Pollock tells us that each pile should be retained in his crushing clamp from *half to one minute or even longer*, and also that it will be generally found necessary (or advisable) to ligature some bleeding points, all of which takes time.

2. *Pain of the operation.*—This again only concerns conscious patients. Patients operated upon with clamp and cautery always tell me that the only pain they suffer is when the pile is first secured in the clamp; the cutting and the application of the cautery they do not feel either at the time or when the clamp is removed. In this respect the crushing clamp cannot possibly be less painful; and if ligatures have to be applied, more pain must be caused.

3. *The nature of the wound.*—Here the cautery produces a carbonaceous eschar; and since charcoal is an acknowledged antiseptic, the only effect that can be produced in such a wound must be beneficial, though probably but to a slight extent. In this respect, then, the clamp and cautery must compare favourably with the crushing; nor can I understand how the slough can be more extensive in the former operation, as Mr. Pollock asserts, since the cautery is only applied to the cut surface, and that while the clamp is still retained *in situ*.

4. *Hæmorrhage during and after operation.*—In mild cases treated by clamp and cautery there is absolutely no hæmorrhage either during or after operation. In severe cases operated upon by me, there has been hæmorrhage during the operation, but to no appreciable extent; while after the operation this has only occurred once. In that case the piles were associated with a great degree of prolapsus, and a considerable amount of inflammation had to be subdued before operative measures could be taken. Here, however, only one gush of hæmorrhage occurred about four days after the operation; but as it ceased almost immediately, I am inclined to think that it was most probably the expulsion of the blood lost during the operation, and which had been retained in the bowel. Anyhow it cannot have been very severe, as the patient in question never thought of sending for medical aid. I believe, too, that in Mr. Henry Smith's hands hæmorrhage rarely results after operation, and, even when it does, it is but slight, and very easily controlled.

5. *Pain after operation.*—This I have nearly always found to be slight, pain being generally felt when the bowels are moved for the first few times. In fact, it is rather discomfort than actual pain that is experienced after the operation.

6. *Liability to erysipelas and pyæmia.*—Patients operated upon with clamp and cautery, I should consider, would probably be placed in a more favourable condition than those who have been subjected to the crushing treatment; for in the latter case, in addition to the clean wound, there would be ligatures serving to keep up a certain amount of irritation.

In conclusion, I may add that I have been led to make these remarks from what I have observed not only in the limited number of cases that have come into my own hands, but also in the large number of cases treated so successfully by Mr. Henry Smith during my period of study at King's College Hospital, London.

I am, Sir, yours faithfully,

THOS. F. CLARKE, M.R.C.S.E., &c.

Somerset East, S. Africa, Aug. 19th, 1880.

LAPSED OR LOST "EPILEPSY."

To the Editor of THE LANCET.

SIR,—It would be very instructive if your readers would place on record instances in which epileptic or epileptiform attacks have occurred once or oftener in life, and not been repeated so seriously as to interfere with health or the duties of life. I have known and heard of such cases, and the experience of general practitioners would be of great value.

I am, Sir, your obedient servant,

October, 1880.

J. G. G.

WHOLE-MEAL BREAD.

THE *House and Home*, in a judicious article on the use of whole-meal bread, its economy and healthfulness, remarks:—"It has come to our knowledge that several of our readers, adopting our advice, and eating only whole-meal bread, have lost all desire for the use of tobacco and alcohol."

Mr. Joseph Hamlyn.—The apparatus described does not appear to differ in any way from one we described recently.

Mr. C. A. Wheeler.—We cannot insert the report of a case save by a professional writer.

A Medical Officer of Health.—Consult Wilson's "Handbook of Hygiene" (J. and A. Churchill).

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—In common with most of my acquaintances, professional or otherwise, I am extremely grieved that the staff of Guy's have deemed it necessary to rescind the letter they wrote to the governors of the hospital, dated August 13th last, in which they expressed their disapproval of the system of nursing, and other innovations introduced by the treasurer, and the governing board. Surely it was a just and temperate letter. Why on earth then need the physicians and surgeons have sought permission to be allowed to withdraw such a communication. This untoward transaction has placed the staff in a very humiliating position in the eyes of their professional brethren, and a ridiculous one in the eyes of the public.

After such an episode in matters medical one can no longer wonder how it is that the poor junior, and in many cases senior, general practitioners tamely submit, through dire necessity, to all the indignities heaped upon them by "Bumble" in the shape of parochial boards, and the stewards of sick clubs, when we find the staff of Guy's truckling (it is a nasty word to use) to the governing body of that institution in a matter which concerns their own dignity, and I may add the honour of their profession. We all know that in every large institution there must be rules and regulations which everyone connected with it must conform to, or all discipline would soon be at an end. Nevertheless, in all things strictly medical or surgical, the respective staffs should have entire control, as they alone are capable of judging for the best in such matters.

It is, I believe, a general opinion (and I think a right one) that the most dignified proceeding would have been for the whole staff to have resigned, there and then; and perhaps when the authorities discovered that none could be found who would fill the vacant posts, they might have been made to feel regret at having treated shabbily, if I may use the term, the body of scientific and honourable men who have done so much to maintain the ancient fame of Guy's Hospital.

What the public have to concern themselves about is, that a noble institution is being injured, and the public have a right to step in and say this shall not be. The governors and treasurer are but trustees of moneys left for a public purpose, and if they fail in their stewardship they will be arraigned at the bar of public opinion.

As I am writing this, it is a great matter of satisfaction and rejoicing to read that Dr. Habershon has resigned. Thank Providence for small mercies, and that there is one man with sufficient *esprit de corps* to stand up for the honour of his profession.

All I can say is, that if the gentlemen who have treated the staff of Guy's with such discourtesy were to serve their domestic servants after the same fashion, they would soon find themselves in the predicament of having to do for themselves what they had been in the habit of paying others to do for them.

Fulham-road, Oct. 23rd, 1880.

Yours obediently,

HENRY W. WILLIAMS, M.D.

To the Editor of THE LANCET.

SIR,—In the face of lay and medical editorial articles condemning the too ready acquiescence of the staff of Guy's Hospital to do as they are ordered by the governors, I and hosts of my medical brethren are anxious to know if the staff have reconsidered their untimely submission. Let them firmly and plainly intimate to the governors that they cannot accede to their demands. By doing so, and asserting their authority in matters purely medical, they will assuredly regain the confidence and be accorded the thanks not only of the profession, but also of the public in general.

Liverpool, Oct. 23rd, 1880.

I am, Sir, yours obediently,

A PROVINCIAL SURGEON.

To the Editor of THE LANCET.

SIR,—I agree with "A General Practitioner" that an opportunity occurred to the staff of Guy's Hospital of asserting their position in the interests of the patients such as seldom presents itself. They might have resigned their appointments *en masse*, and at the same time offered to fulfil their duties till others were found to take their places. Under these circumstances, no one, I venture to say, would have come forward, and the present Guy's staff would have had to remain at their posts, and the committee of the hospital to reconsider their position. The state of affairs is now unfortunately entirely the reverse.

Your obedient servant,

October, 1880.

A LOOKER-ON.

* * The above letters may be taken as specimens of the communications in which many of the profession express the view of this question that prevails. Unfortunately the resignation for which Dr. Williams records his thankfulness has not taken place.—ED. L.

CHEAP DOCTORING.

M.R.C.S., &c.—We regret that for the present we cannot insert more letters on the above subject, to which we have given already a large amount of space. We regret this the more as the letter of "M.R.C.S.," from his point of view, is very interesting and forcible, but not convincing.

Parateretes is thanked. The matter will be noticed next week.

M. O. H. desires to put the following questions and case:—

1. Can decomposing or putrid sewage getting into drinking-water give rise to enteric fever? or
2. Must the sewage actually contain the excreta of a patient suffering from typhoid in order to propagate the disease?
3. Is enteric fever likely to be contracted under the following conditions? A common sewer, serving a population of 2000, has for years discharged its sewage into a tidal river near its mouth. Except at spring tides, the mouth of the sewer and the adjacent mud-bank are open and exposed. The mud-bank is thoroughly impregnated with sewage. The situation being open and breezy, there is, as a rule, no great smell; but in hot, dry, and still weather a most foul and offensive odour arises from the place. Such conditions did prevail during the latter part of August and early part of September, and the stink was continuous and especially nasty. A public road runs close by. Query. Can a passer-by, who would probably be exposed to the influence of the stink for a quarter of an hour or so in going and again on returning, thus contract enteric fever, there being at the time no existing case in the district?

Disgusted.—It is a case for prosecution and exposure. Until the law is amended, it is no use expecting the Medical Council or the Registrar-General to prosecute. The profession of the locality should do so.

CERTIFICATION OF INSANE PAUPERS.

To the Editor of THE LANCET.

SIR,—In answer to the letter of "Subscriber" in your last issue, it seems to me that a contract between a board of guardians and a medical man for the certification of insane paupers for a fixed sum cannot be legal; for under the Lunacy Acts it rests entirely with the magistrate to decide as to the medical man he will call to his assistance; and secondly, it rests with him to decide alone what fee the board of guardians shall pay the medical man for the certificate. The duty and business of the guardians appear to be confined to paying. It will be seen on referring to the Lunacy Acts that boards of guardians appear to be specially ignored; but that medical officers, relieving officers, and overseers are liable to penalties for breaking the Lunacy Laws, boards of guardians having but to pay all the expenses.

I cannot help thinking that it would be very desirable to place this question in the hands of the Poor-law Medical Officers' Association, and to ask their able and energetic President, Dr. Rogers, to obtain from the Local Government Board their legal opinion on the subject. This would form an effectual check on parsimonious boards of guardians in the event of the contract being an illegal one.—Yours &c.,

Oct. 25th, 1880.

M.D.

To the Editor of THE LANCET.

SIR,—Pauper lunatics are admitted to asylums on the order of (a) a justice of the peace, and of (b) the officiating clergyman and the relieving officer.

In the first case, the justice who orders the medical examination of an alleged lunatic can make an order upon the guardians of the poor for the payment of a fee not exceeding one guinea to the medical man who makes the examination, whether the alleged lunatic is in consequence sent to an asylum or not. In the second case (b), there is no provision for the payment of any expenses attending the examination and removal to an asylum of the supposed insane person; but Fry says that "apparently the relieving officer would be justified in charging in his accounts the reasonable expenses necessarily incurred in the discharge of his duties cast upon him by the statute. Any charge so made will, of course, be subject to the auditor's revision, both as regards its legality and its reasonableness."

No contract such as that spoken of by "Subscriber" is provided for by the Lunacy Acts. I should advise him and his brother medical officers to retire from it, unless the Poor Laws, with which I am not familiar, permit it.

I am, Sir, yours &c.,

Oct. 25th, 1880.

MEDICAL SUPERINTENDENT.

M.B., C.M.—315, Oxford-street. The information required may be obtained of the Registrar.

Chirurgus has forgotten to enclose his card.

Mr. Thomas Bond.—Next week.

CURIOSITIES OF ADULTERATION.

To the Editor of THE LANCET.

SIR,—In your last issue (page 680) is a short paragraph on the above subject. What think you of the following:—

I am at the head of a town school, and a short time back gave Bread-making to a class of boys as the subject for an essay. One of the essays began in school-boy English:—"The first thing in bread-making is to boil the potatoes, and then you must peel them and mash them carefully. Then you must mix them with a little water, and set them in a warm place till they begin to ferment," &c. &c. Oddly enough, *flour* was not mentioned in the course of the essay. The boy's father is a baker.

Yours obediently,

October, 1880.

SCHOOLMASTER.

ANTISEPTIC MIDWIFERY.

Referring to Mr. Verdon's article in our pages on Sept. 25th, Mr. ARTHUR RICHARDSON, of The Firs, Rusholme, writes:—

"I have for the last two years freely used carbolic acid mixed with castor oil, in the proportion of 1 to 7, as a lubricant to all instruments for all manipulations in midwifery cases, and the result has been so uniformly successful in averting complications where experience would have led me to expect them, that I strongly advocate the careful notice by the profession of Mr. Verdon's treatment.

"I was first led to use carbolic acid in midwifery manipulations and as an after-application to the parts of the mother injured by laceration, bruising, or long-continued pressure, &c., from a discussion which took place in non-medical papers on the value of Calvert's carbolic oil for use by shepherds, and the overwhelming testimony given in its favour by them.

"Midwifery instruments are frequently apt to be washed by the nurse, after the hurry and bustle of a difficult labour, in a very imperfect manner; if in this state they are allowed to lie until next required, it is evident that unless they receive some antiseptic precautionary measures they may prove a fruitful source of septic mischief, and in like manner the argument may be extended."

Enquirer.—Scarcely.

Dr. Reginald E. Thompson's paper will appear in an early number.

A. D. O'C. F.—Yes.

A QUESTION IN SANITATION.

To the Editor of THE LANCET.

SIR,—I have as an architect thought myself justified in turning the overflow pipe of a soft-water tank, filled from the gutters of an isolated house in the country, into the only well of pure spring-water belonging to it. This was done on finding that the ditch into which it was intended to carry the overflow was at too high a level, and thinking that the occasional influx of rain-water to the well would not be injurious. Is it your opinion that the water in the well would be so contaminated in consequence of this as to render it unfit for drinking or culinary purposes? Or would it not rather be improved by the introduction of the soft water? Do you think my employer is justified in describing this arrangement as "murderous"? The rain-water tank contains 1800 gallons, and takes the fall from thirty-two squares of slated roofing, conducted into it by glazed drain-pipes jointed in cement.

If you would let me have your idea as to the above I should esteem it a favour.

I am, Sir, yours faithfully,

October, 1880.

BETA.

* * There is no objection to the rain-water *per se* going into the well. The difficulty arises from the chances of pollution to which rain-water is exposed in the collection and storage. Upon these chances, in the particular case, we can express no opinion. They must be judged of on the spot. If there were no necessity to supplement the supply of the well by the overflow of the rain-water tank, we should have held it best to have provided for the overflow in some other fashion. Why not (the circumstances of the locality being suitable) by a series of subsoil drains—by sub-irrigating a plot of ground, in fact, with the overflow!—ED. L.

BARMOUTH AS A HEALTH-RESORT.

To the Editor of THE LANCET.

SIR,—From the comments upon Barmouth in your number of the 9th inst., one might suppose it was the seat of all kinds of infectious disease; but my experience for the last eleven years as medical practitioner here is just the contrary. During that period the town has been remarkably free from any kind of zymotic disease; and whenever there has been any isolated case of measles, scarlet fever, or diphtheria, it has been imported by visitors, and has not extended as it would in some districts. Last year the rate of mortality from all diseases amounted only to 10 per 1000, and I might add that four of the deaths happened amongst visitors; one was due to drowning, and one occurred the first night after arrival. If we deduct these four cases, the rate of mortality amounted only to a little over 8 per 1000 per annum.... It is true that the drainage has not been opened yet, but no doubt will be before next summer, as it is being constructed, and when completed it is to be hoped that it will be as effectually done as at Torquay....

Yours faithfully,

Barmouth, October, 1880.

H. J. LLOYD, L.R.C.P., &c.

CHIAN TURPENTINE.

To the Editor of THE LANCET.

SIR,—In the *Pharmaceutical Journal* last week Professor Flücker suggests the probability of a supply of true Chian turpentine being found in Algeria. By letters received this week from competent authorities in that country, who have been making inquiries and searching for the trees, they report that the true *Pistacia terebinthus* tree is hardly known and very rare in Algeria. The *Terebinthus atlantica*, Desf., is the nearest variety that is found. A sample of the gum is sent for comparison. They are continuing the inquiries among the Arabs, and agree to distribute samples of true Chian that I am sending to the traders going into the interior. Mr. C. Hanbury informs me that his collector writes that, although he has found some more trees of *Pistacia terebinthus* in the islands, the Government will not allow them to be touched, with the view of tapping them, for fear of destroying the tree.

Yours truly,

London, Oct. 20th, 1880.

THOS. CHRISTY, F.L.S.

LITHOTOMY.

To the Editor of THE LANCET.

SIR,—On the 29th ultimo I operated on a boy, aged six years, for stone by the lateral operation for lithotomy, and, from its size, with some difficulty extracted a uric-acid calculus, weighing one ounce three drachms. I give this case as I think it very unusual for a stone of such magnitude to be taken from so young a child. The boy did well, and is now running about in perfect health. Yours faithfully,

Wivenhoe, Essex, Oct. 26th, 1880. C. A. S. LING, M.R.C.S., &c.

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Medical Diary for the ensuing Week.

Monday, Nov. 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

MEDICAL SOCIETY OF LONDON.—8½ P.M. General Meeting.—Dr. F. de Havilland Hall, "On a Case of Pleuritic Effusion." Dr. E. Symes Thompson, "On a Case of Aortic Aneurism in which Secondary Disease was set up in the Right Lung."—Dr. J. C. Thorowgood, "On a Fatal Case of Atrophy of the Stomach."

Tuesday, Nov. 2.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following Specimens will be shown:—Myeloid Tumour of Femur; Multiple Exostoses; Specimens of Ainhum; Embolism of Cerebral Artery; Fibro-cellular Tumour from Knee-joint; Epithelioma of Lung; Papilloma of Umbilicus; Joint Disease in Tabes Dorsalis (living specimen); Histology of Molluscum Contagiosum; Telostitis in a Syphilitic Infant (living specimen); Dissection of Cleft Palate; Urticaria Pigmentosa; &c. &c.

Wednesday, Nov. 3.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be exhibited by Dr. Roper, Dr. Herman, and others.—Papers: Dr. Wade (Birmingham), "On a Case of Chorea in Pregnancy successfully treated by Dilatation of the Cervix Uteri."—Dr. Braxton Hicks, "On Congenital Abnormality of the Uterus simulating Retention of Menses." Dr. Charles H. Carter, "Absence of the Vagina; Uterus Distended by Retained Menstrual Fluid; Operation; Recovery."

EPIDEMIOLOGICAL SOCIETY.—8 P.M. Inaugural Address by the President.—Mr. Netten Radcliffe, "On Certain Appearances of Cholera since 1873 in the Countries lying between India and Europe."

Thursday, Nov. 4.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

An Address ON THE TREATMENT OF PUERPERAL FEVER.

*Delivered before the Midland Medical Society at Birmingham,
Oct. 20th, 1880,*

By J. MATTHEWS DUNCAN, M.D.

(Concluded from p. 685.)

SEPSIN, or chemical products of decomposition dissolved in water are absorbed by the extensive mucous surfaces of the vagina and uterus, with their lymphatics, and by the placental and other wounds in the genital tract. Or they pass freely into the uterine sinuses and thus into the general circulation. The result is quick pulse and respiration, high temperature, delirium, and often purging. If the poisoning is slight, symptoms are slight. If the poisoning is by a large dose the symptoms are urgent, and death may result, and this without any added septicæmia to produce the fatal event.

During the currency of the disease or poisoning there is the possibility of a cure, almost sudden, by removing the fetor or stopping the supply of the poison. Nothing is more striking or more gratifying in the whole practice of medicine than this sudden recovery; and, as it is often produced by art, it deserves the name of a cure. A patient in the most alarming condition, apparently within a few hours of death, is appropriately treated, and within a few hours alarm has entirely subsided. It is not in lying-in women alone that such cases are seen; but sapræmia is more frequently observed in them than in others, and the joy of recovery is greater because the foreseen danger is greater, for evident reasons.

An aggravated case of this kind was recently under my care in St. Bartholomew's Hospital, and I shall give you a sketch of it from the notes of Mr. Nall. The largeness of the retained placental mass made the cause of the disease evident and easily discovered; and in this respect it is not like the run of similar cases which are classed under the designation puerperal fever. The recovery in it was so great, so quick, and so nearly complete, as to be scarcely credible. The woman appeared to be at the point of death. It was apparently not worth while to disturb her by treatment. In a few hours after the treatment she was comfortable, and every alarming symptom had disappeared. Yet for some days there was slight recurrence of fetor and persistence of diminished symptoms, but not to such a degree as to cause any suffering or alarm for the ultimate safety of the patient. Were the case not a typical one I should not take up your time with it.

A. E— was delivered naturally of her second child on June 8th. Flooding occurred after the birth of the child, and slight blood loss continued for seven days. Then the lochia became fetid. On the eighth day she had rigors, which were repeated daily. She was brought into the hospital on the tenth day, and was delirious during the night. On the eleventh day of her lying-in, when I first saw her, she had no complaint of pain, was pale, sick, frequently vomiting, troubled with diarrhoea; the uterus tender; breath sweet; respiration hurried, 44; pulse 146; temperature 104°2'; copious flow of stinking lochia. A piece of placenta was removed from the vagina. Under the influence of chloroform the hand was introduced into the uterus, which was soft and easily admitted it, and adherent placental masses were removed, some small shreds being left after many had been separated by volsella. The whole genital tract was then washed out by copious injections of carbolic lotion (1 in 30). Ergot of rye was administered, and the uterus was washed out every four hours during the day. The report of the next day bears that she had a good night without delirium, that the bowels had been twice moved, the motions being thin, yellow, and offensive. The discharge was slight and slightly fetid; the breasts were tender and swollen; the pulse had fallen to 100, the re-

spirations to 36, and the highest temperature was 101°4'. The whole aspect of the case had changed from despair to hopefulness. Ergot was continued for some days, and the carbolic washings as long as any trace of fetor was found. Recovery was uninterrupted; indeed, it may be said there was no process of recovery, there was only convalescence. Such a progress is not seen in any other form of puerperal fever. The theory of sapræmia accounts for the rapid cure, while the theory of the other forms of puerperal fever explains their gradual advance from bad to worse, or to recovery.

Sapræmia is treated earnestly, even heroically if necessary, with a view to its own cure, and with a view to the prevention of the complications, inflammatory, septicæmic, or pyæmic, which it is very likely to bring in its train. Heroic treatment may be required to reach the remotest part of the genital tract in search for decomposing matter, or to ascertain that there is nothing but putrid lochia in the case. Mere vaginal washing may suffice, or intra-uterine washing, or the volsella may be passed into the uterus to grope for the decomposing structure, or with the same view a finger or fingers may be passed, or even the whole hand; and it may be necessary to dilate the cervix preliminarily. Most of this may be done without an anæsthetic, but where the hand is to be introduced into the vagina, the previous induction of anæsthesia is desirable.

The lotion which I always use is the carbolic, of the strength of 1 in 40, or occasionally 1 in 30. It is used tepid or warm. In conducting the operation it is necessary to be very gentle, to avoid the introduction of air into the passages, and to see that the fluid runs out freely. If the os uteri externum and internum are not widely open, a pipe with double current should be used. The whole proceeding should cause little or no pain, and, for an ordinary washing, a pint or a pint and a half may be passed. But if the discharges are copious and fetid, more may be required, and the rule is to continue the injection so long as it comes away foul or perceptibly fetid. Of course, a bowl is to be so used as to receive all the lotion as it is discharged, in order to save the bed-linen from being wetted. When the uterus is washed out the medical attendant conducts the operation, but vaginal washings may be left to the nurse. The washings are to be repeated from twice to four times a day if the fetor persists in the discharges. After the fetor is suppressed twice a day is sufficient. If the discharges become natural, and if the symptoms of sapræmia disappear, the washings are stopped. In any case they are required only for a few days.

These antiseptic washings constitute the great or essential treatment of sapræmia — a treatment, as already said, so direct in its action, and so successful, that it may be called a cure. Though these washings have been described by ancient authors, and though they were recommended by Harvey and by Bauloquoque, it is well known to you that no such practice was in use among us till the antiseptic theory of treatment was promulgated. Yet they are not covered by the antiseptic theory, for you know it was based on the presence of bacteria which passed into the blood, and the antiseptic treatment was planned to destroy them or prevent them reaching the wounded surface. Here we use antiseptics not with these views, but to remove and arrest putrefaction, with a view to stopping the supply of a chemical, not a living, poison, the product of putrefaction, which enters the blood and endangers the constitution.

Besides the washings out, a case may demand many attentions, and cares too varied and too uncertain of occurrence for me to enter on them here. But to one I must allude as probably directly useful. It is the administration of ergot. A drachm of the liquid extract, in divided doses, should be given daily for a few days. The object of its use is to induce permanent contraction of the uterus or uterine retraction. This diminishes the uterine cavity, in which the discharge accumulates; it thus also lessens the surface absorbing the putrid poison, and the contraction of the walls of the organ may to some extent prevent the passage of the fetid fluid along the vessels into the circulation. Of course, should it be desirable, the drug may be given hypodermically, ergotin being used instead of the liquid extract.

Perhaps I have made the pathology of sapræmia too simple; for, in addition to what I have said, it is necessary to add that fetid lochia do not always poison the constitution. They generally do so, but not invariably. They may flow in intense putridity, and yet be apparently not absorbed, as is generally the case. Why the putrid

ichor is in some cases not absorbed I shall not here attempt to explain.

I know no reason why septicæmia and pyæmia should be called *real* puerperal fever, yet this is a common mode of speaking. The simple inflammatory fever, and the sapræmic fever, are not less really fever, nor less really puerperal. Probably the notion arises from the fact that grave cases of fever after delivery are for the most part septicæmic, or pyæmic, and that the great majority of the deaths in childbed is produced by these diseases. There has always, indeed, been a tendency to regard puerperal fever as desperate, or almost certainly fatal. I can remember well the saying of an eminent physician, with whose retrospective diagnosis many agreed, that if a case recovered it was not one of real puerperal fever. Probably he did not mean his words to be held as strictly true, but to express his sense of the hopelessness of such cases. This disheartening opinion should not be entertained, for it is not based on ascertained truth, and it induces despondency and feebleness in treatment which are prejudicial to the thorough management of a case. The pyæmic cases with their embolism, inflammation, and abscess, are more dangerous than the septicæmic, but even in pyæmia there are numerous recoveries. Every one has heard of rare and marvellous convalescence in pyæmia, even after several joints have suppurated; but these are very far from being the only instances. Many less severe cases survive the disease.

I may consider simultaneously the treatment of these two diseases. They are often combined, and their treatment is identical, if we except such surgical interference as is sometimes required in cases of pyæmia, a department into which I do not propose to enter. I have said that pyæmia and septicæmia may be combined, and while this is probably a frequent occurrence, it should also be remembered that all the forms of puerperal fever may be simultaneously present in one case. The separate consideration of simple inflammatory fever and of sapræmia is demanded by their utterly different pathology, and by their distinct indications of treatment. For the inflammatory fever we have some modification of the venerable established antiphlogistic method. For the sapræmia we have the arrestment of the putrid poisoning. For the septicæmia and pyæmia we have no treatment in any sense antidotal or curative in the humblest meaning of that word.

Cases of pyæmia and septicæmia are to be managed rather than treated. The word treatment implies too high an estimate of the physician's powers; or if not too high, at least a too definite view of them. We cannot arrest or even moderate the storm, but we may guide the bark through it. When the organisms producing these diseases are in the blood we cannot kill them, nor do we know any means of certainly controlling their growth. But we may wisely consider the constitutional and local circumstances of the patient, and judiciously interfere to modify them with a view to the patient's survival.

One unsound tree in a forest may be covered with lichen and fungus, and the tree may slowly die, or be killed. But it may survive, and becoming healthy, throw off the morbid growth which endangered it. The organisms of pyæmia and septicæmia find a favourable nidus for development in the weak, the unhealthy, the hopeless, the ashamed, the sad—in those who have been exhausted by a long labour or injured in the course of a severe one. But the attacked do not certainly die. The organisms may grow and grow, and cause death, but they are not necessarily fatal; their growth may be arrested, and they may all disappear. Debilitating and depressing conditions favour their development. Health and strength favour their disappearance. These principles are the foundation of our management; and experience, daily increasing, confirms the conviction that the foundation is not laid on sand.

Good nursing, careful feeding, prudent stimulation—these are the great points. In all of them there is now progressive improvement. While it is impossible to appreciate with any exactness what we owe to these, no one will deny the comparatively great advantages we now gain by them. It would be out of place to enter upon the subject of nursing here. It is no peculiarity of cases of septicæmia and pyæmia to require good nursing, and the subject is specially referred to in connexion with these diseases because, in default of any direct treatment, we specially consider what remains for us to attend to.

On feeding and the use of stimulants I might content myself by making the same remarks as on nursing; but I

wish to insist on the great necessity for more attention being paid to the niceties of these important departments. The food and drink should not be left altogether to the nurse. In quality, quantity, and time they should be regulated; and this cannot be done by previously fixed rules, but by directions modified according to the observations daily or hourly made in each individual case. Milk and beef-tea are the staple of the patient's diet, and they may be varied almost infinitely, to suit minor emergencies as they arise. In regard to food, the general rule is to give as much as the patient can take without evident disorder arising from it. It is seldom that too much is taken, for a common difficulty lies in overcoming the aversion to food.

The use of stimulants requires a little more discussion. At present the favourites are brandy and champagne, and I adhere to the general voice in preferring them—on one condition, that they be really good. At the same time I make no objection to other wines and spirits. Brandy and champagne are common and simple, and, for me at least, it would be only an affectation of refinement to appraise the merits of different wines and different vintages. But I am sure that, in regard to all stimulants, our aim should be to use as little as possible. Often, at least for a time, none at all is required. Occasionally, but rarely, in a crisis of weakness, brandy is to be administered largely. Always the principle holds good that too much will do more harm than too little. I am sure that it is a common error to give too much. Excess of food may be passed along the *primæ viæ* without entailing any considerable injury; not so excess of alcohol. Food is rarely desired by the patient, while she often wishes alcohol; because, as it is given, it assuages thirst for a time and produces at once an agreeable excitement.

A sketch of the treatment of septicæmia and pyæmia would be bald and imperfect if it were confined to the paramount matters—nursing, food, and stimulants. Great attention has to be paid to the general condition and to the state of health as indicated by prominent symptoms. Iron and quinine are now frequently administered, and with great advantage; and what a change of view does this imply if we look back to the days of Gordon, or even of Ferguson? I can well remember the astonishment and unsettlement of mind produced by the recommendation of Hamilton Bell to use the old tincture of the muriate of iron in erysipelas, and I frequently witnessed the earliest employment of the same remedy in the cognate diseases now under discussion, chiefly by the advice of the elder Begbie. It was always the custom to combine bitters with the iron, but now the regal bitter, quinine, is used, not only as a stomachic vehicle, but with the direct purpose of reducing the temperature whose regular observation helps so greatly to guide us now—a chart unknown in the days of Bell and Begbie. Besides quinine and salicin, the influence of cold is now familiarly resorted to reduce temperature when it rises above 102° or 103°, and this is done with the result of giving comfort and securing probably real gain. Many physicians, Schroeder, Osterloh, and Spiegelberg, in Germany, and especially Playfair in this country, have used the cold bath to reduce temperature when it is very high; but I have no experience with it. Temperature does not long remain high in this disease, varying greatly and often rapidly; and for keeping it moderate, quinine or salicin, in large doses, with regulation of the heat of the room, of the bedclothes, and of tepid sponging, are generally sufficient.

Ice is often taken internally against thirst, and it is a delicious mouthful; but the craving thirst is not relieved. The dose is repeated and repeated in vain. For the relief of thirst, the old remedies, such as toast-water, have more real value. But the urgency of thirst is minimised by the proper management of the case. At least, I can have no doubt that in the days of what I call the excessive use of wine or brandy, or of opium, we heard a deal more of the suffering from thirst than we do now.

Ice is much used to arrest vomiting, which is so common a symptom of the peritonitis of puerperal patients, and it is sometimes effectual. For this distressing symptom remedies are numerous, and their largeness of number is evidence of their uncertain action. The best is of course that most used—the hydrocyanic acid and bismuth mixture, without or with morphia.

With or without sickness and vomiting there may be flatulence, and it is sometimes so great as to embarrass the heart and lungs. In extreme cases relief has been afforded by letting off the air by a small trocar and cannula, but of

this proceeding I have little experience. The remedies which I have found of most use are charcoal, in teaspoonful doses, given in water once or twice daily; or turpentine, in ten-drop doses, given in water or some simple vehicle, three or four times daily.

The hot linseed-meal poultice is almost always a grateful and useful application to the hypogastric region, relieving pain and promoting the lochial flow. Besides, when the skin is hot and dry it is a valuable diaphoretic.

Opium in some form is invariably administered, and almost always with advantage. Occasionally, indeed, it produces great mental disturbance and uneasiness, or vomiting, or dryness of tongue; and, in such cases, if a change of the preparation does not bring better results, the medicine may have to be given up, or used only to produce sleep. Indeed, apart from any injurious effects, it is often a good plan, when pain is not urgent, to give it only to secure a good night. But generally it is given repeatedly during the day, either to relieve pain or with a view to its soothing and supporting rather than narcotising action.

Opium and other remedies are also often used against diarrhoea, and in this way much good may be done. But it is necessary to pay much attention to this purging, generally of thin highly coloured dejecta, for undoubtedly it often should be encouraged rather than checked; and, perhaps fortunately, it is often not easy to check it. The physician should see all the motions, so as to justly estimate their quantity and character, and he should not regard it as his duty to try to check free and even copious evacuations, or to get the stools in a formed state. He will be guided in his judgment on this point by the strength of the patient and the amount of food consumed.

During the whole course of the disease the regular flow of the lochia is anxiously looked for; and should they be suppressed, an attempt is made to bring them back by hot fomentations to the vulva and hypogastrium; for it is naturally regarded as desirable that there should be lochial discharge, and that it should not be retained. But besides its mere flow, the character of the discharge, especially as to fetor, is scrutinised. If there is fetor there is probably sapræmia complicating the septicæmia or pyæmia, and this fetor is treated by antiseptic lotions, as already described. But fetor of discharges forms no part of septicæmia or pyæmia. The bacteria or micrococci of these diseases flourish when there is no fetor. At present, however, such is the enthusiasm for antiseptics, that it is considered desirable to have the womb well washed out once or twice daily by carbolic lotion, even when there is no fetor; and meantime I consider it good practice to do this twice daily while there is urgency, if the discharges are not quite healthy in all respects. The intra-uterine washing cannot work upon the infected blood circulating everywhere in the body, and carrying with it the baneful organisms, but it can keep the wounds clean; and, if the womb or vagina is a nursing-ground for farther supplies of these organisms, then by the antiseptic washing the nursery is destroyed. The farther supply of the contagium vivum is stopped, for the micrococci are killed by the carbolic wash.

Such, gentlemen, is an outline of the treatment of a group of terrible diseases. How imperfect it is no one can feel more strongly than I do. It is not a fixed treatment, but the treatment of to-day. Were I the wisest therapist and had I the best rhetoric, my description would still be imperfect; for no one can describe, with a near approach to perfection, what is imperfectly known and very dimly understood. But the variations of health and constitution, of complications, and of other conditions, are so numerous that a perfect theory or system of treatment would not carry with it directions for every individual case. Boundless scope, after all, would be left for intelligent interference of the practitioner warmed into zeal by a kindly sympathising heart.

Meeting with these puerperal diseases, the practitioner dare not fold his hands in apathy and inaction on account of the incompleteness of his knowledge. No one would listen to him were he to proclaim that all our experience and all our laboriously acquired information had yielded no fruit for the benefit of suffering women. He is face to face with great and terrible danger, yet his position is not one of imminent peril to himself as in the case of a soldier, who, like him, has to meet unexpected combinations and unforeseen difficulties, and who, whether he has little or much knowledge, must act and that at once, for in boldness there is safety, in delay there is only disaster; and experience has amply demonstrated that no case is to be utterly despaired of till the moribund

state supervenes, however severe and complicated it may be.

We have said that puerperal fever affects especially the weak, the unhealthy, the hopeless, the ashamed, those who have been exhausted by a long labour or injured in the course of a severe one; and there is no need to expatiate on the great field here opened up for the beneficent activity of the physician. To strengthen, to heal, to encourage, to console, to manage labour, to reduce injuries to a minimum, are all objects to be kept in mind; not indeed with a view only to the treatment of puerperal fever, but in order to its prevention. It is a trite saying that prevention is better than cure, and I think there can be no doubt that more suffering is avoided and more lives saved on this principle than by treatment; and I feel impelled to say a few words on this subject.

The prevention of simple inflammatory and of sapræmic fever demands no special consideration here; it is the prevention of septicæmia and pyæmia, or of contagious puerperal fever, that is generally in view when prophylaxis is spoken of, and few subjects are at present more discussed. The late trials of midwives for spreading puerperal fever, and the reiterated attacks on maternity hospitals, are familiar to all; and I believe all will admit that we want much more light and more wisdom in our dealings with these matters. They are not identical, for the propagation of puerperal fever in a hospital involves considerations which have no place in its propagation in a private or out-of-door dispensary practice. Hospitals are the seat of epidemics of fearful character. The house becomes tainted, and every lying-in woman in it is in great danger from the infection. Fortunately, the infection does not become so intense as to affect all, but such a degree of intensity is quite conceivable. In an ordinary dairy no vessel of milk escapes the action of the bacterium lactis; every dish becomes curdled. In home practice the infection reaches patients only sporadically; the disease, however, occasionally dogging the footsteps of an individual practitioner. There are no epidemics, no prevalence of the infection over countries. A lying-in woman can easily find a safe home. The analogy of the curdling of milk does not apply here, for it is difficult to find a place where there is no bacterium lactis where milk does not curdle.

Against the dangers of both hospital and home practice we find some degree of protection in antiseptic midwifery, a great practical subject which I have discussed in an address lately given to the Medical Society of London. Antiseptics have, as yet at least, but little to do with the treatment of the infectious forms of puerperal fever; they avail greatly in the prophylaxis. This has been well exemplified in the case of hospitals. In private practice the protective power is not so easily demonstrated; yet I believe the plan is there also invaluable, rendering the patient comparatively safe and practically excluding all danger of infection by the careful accoucheur.

Ventilation and cleanliness were, up to the present time, the great resorts of medicine against epidemics of puerperal fever, and they had little and only temporary effect. They are, however, even now justly valued very highly; but, with antiseptics, we come into closer quarters with the enemy we have to subdue, and have a weapon of greater potency, and consequently we have more success. In spite of all our prophylaxis, however, puerperal fever prevails. The enemy succeeds in the attack and the physician has to make every effort to rescue his patient by treatment.

Although we have at present no prospect of being able to stamp out the infectious forms of puerperal fever or of reducing them to comparative insignificance, there is yet, even as to the attainment of these great ends, some ground for hope arising from the success of scientific investigations. Vaccination seems destined only to a brief further protraction of its splendid and useful isolation and of the mystery of its operation. The results of Pasteur's researches on the cholera of the domestic fowl and of Toussaint's and Greenfield's on anthrax show how a contagium vivum may have its potency diminished, or nearly annihilated, by methods having a strong analogy with those employed to reduce the potency of the variolous contagion. If one contagion can be so modified, we are led to ask, Why may not also that of puerperal fever be likewise? There are other researches by Greenfield and Buchner which justify the philanthropic hope that with lapse of time the deadly characters of the organisms of septicæmia and pyæmia may be changed into others more innocent. Such anticipations are little more than mere indulgence of the scientific imagination; but

they are far from being useless or foolish, though to the merely practical man they may appear so.

The ideas suggested by the researches of Pasteur, of Toussaint, of Greenfield, and Buchner may prove to be mere *ignes fatui*, but they may, on the contrary, prove to be true guides. It is by following out such ideas, verifying or disproving them by new investigations, that progress is made in science. Progress in science is a fountain of purest pleasure to its promoters and of widespread beneficence to mankind.

The Society whose new session I have the honour to inaugurate is devoted to the advancement of science, and I dare in conclusion to suggest to every busy medical man here that he should make some department of it, perhaps a very small department, his peculiar study. By so doing he will keep a special perennial joy in his life of toil: he will be, if not a discoverer of new truth, at least a diffuser of it; he will be a useful and honoured member of this Society, he will contribute to the elevation of medicine into a more and more useful profession, and of his medical brethren into a higher and higher position.

The healthy and diseased human body is not the greatest matter in the universe of things. Our profession acknowledges that there are others to whom, in respect of the value and grandeur of its aims, it willingly bows. But medicine offers more than sufficient scope for the greatest efforts of the greatest minds. It is for us to contribute to its prosperity and progress. *Floreat res medica.*

Address AT THE

OPENING OF THE ANATOMICAL DEPARTMENT

IN THE
NEW BUILDINGS OF THE UNIVERSITY OF
EDINBURGH.

Delivered October 27th,

By WILLIAM TURNER, M.B., F.R.S.,
PROFESSOR OF ANATOMY.

WE meet together this morning on an occasion which will be for ever memorable in the history of this University and of the Chair of Anatomy. We inaugurate that portion of the new buildings of the University which is to be devoted to the study and teaching of anatomy, and in celebrating the accomplishment of the first stage of the great task of providing new buildings for the accommodation of the Faculty of Medicine, we may congratulate ourselves upon entering into the occupation of apartments which, in their spaciousness and the convenience of the arrangements they provide for the purposes for which they are designed, are unsurpassed in the British Empire.

It is now about ten years since the authorities of this University began seriously to consider the necessity of extending the buildings. Various causes had combined to make this a necessity; a considerable increase in the number of professors and in the subjects taught since the existing buildings were erected, requiring an addition to the number of class rooms; an annual growth in the number of students, causing the class rooms to be too small to give the proper accommodation; a complete change in the character of the teaching of many of the subjects, more especially those of medical study, owing to the development of practical methods of instruction, and the inefficiency, both as regards number and size, of the apartments used for that purpose; the natural growth of the museums of the University, which by the accumulations of years had outgrown the space allotted to them.

At the first it was thought that, if new buildings were provided for the large departments of anatomy and chemistry, a sufficient amount of space would be set free in the existing buildings for the accommodation of the other sub-

jects of study requiring an extension of room. On further inquiry, however, the Senatus became satisfied that the needs of the various departments could not in this way be properly provided for; and, after a full consideration of all the circumstances, it was decided that the proper course to take was to devote the existing University buildings to the services of the faculties of arts, divinity, and law, and to transfer the medical faculty to a new building, which would at once afford sufficient accommodation for lecture rooms, museums, laboratories, and other apartments for practical work.

The question of a site for these new buildings had then to be settled, and as it had been decided by the managers of the Royal Infirmary to remove that great institution to the site on which it now stands, the ground on which it then stood was looked upon as suitable for the purpose. Accordingly negotiations were entered into to acquire the old infirmary site for university purposes, but in the course of time the negotiation fell through, and it was fortunate that it did so. For if this scheme had been carried out, then the construction of the new buildings of the University could not have been commenced until the present year, after the managers had vacated the old infirmary; and if they had been constructed there, then the medical school of the University would have been at an inconvenient distance from the new infirmary. It was therefore resolved by the Senatus to acquire, if possible, the ground of Park-place and Teviot-row, and the means of effecting a considerable portion of that purchase was provided by a bequest of the late Sir David Baxter, who, in this as in so many other matters, proved a wise and liberal benefactor to the University.

A subscription was then set agoing to procure funds for the purchase of the rest of the site, and the erection of the buildings thereon; and through the exertions of a committee of public-spirited citizens, presided over by the Principal of the University, for whose services in the promotion of this great work we must for ever feel deeply grateful, and having as two of its most zealous members the late and the present Lord Provosts of the city, a sum of about £80,000, in addition to the Baxter bequest was raised. The Government was then appealed to for assistance, and a grant from the Treasury of £80,000 was obtained.

Whilst these important financial arrangements were being made, the architect, Mr. R. R. Anderson, was preparing the plans. The instructions that he received were to provide each subject of medical study with a distinct lecture theatre, and with rooms for practical study appropriate to the teaching of that subject; that the rooms should be spacious, well-lighted and ventilated, and conveniently arranged; that there should be a large anatomical museum, and that the departments of anatomy, surgery, pathology, and practice of physic should be grouped around the museum, so as to have convenient access to it for specimens. Two years ago the foundations of the building were begun, and now we welcome you in the department which has first been completed. How well the architect has accomplished his task, an inspection of the rooms devoted to anatomical teaching and study will show you, and you will not fail to see that he has set this and the other departments in a casket of stone of which the University may feel proud to be the possessor, which is an ornament to the city, and a witness to the truth of the saying that

"A thing of beauty is a joy for ever."

And now, gentlemen, let us take a rapid survey of the origin of the school of medicine of this University, which dates from the first quarter of the last century—a period which marks also the rise in a more or less complete form of medical schools in several of the other universities in these islands. Up to that time, as was not unnatural, when we consider that so many of the universities either owed their existence to papal bulls or were modelled under their influence, these academic institutions had been almost exclusively regarded as training-schools for ecclesiastics and for promoting the study of theology. But at the beginning of the last century a great national awakening to the need of instruction in other departments of knowledge took place, which led in this University to the institution of the faculties of both medicine and law.

It is true that lectureships and professorships of medicine had been founded in many of our universities at an earlier period. In Aberdeen, for example, a "Mediciner" was appointed so long ago as 1522. In Oxford and in Cambridge regius professorships of physic had been founded by Henry the Eighth about the middle of the same century. The pro-

fessorship of physic in Trinity College, Dublin, dates from 1618. Professors of medicine were also appointed in this University in 1685, but it does not appear that they ever attempted any systematic teaching.

It is impossible, indeed, for a school of medicine to have vitality until provision is made for teaching anatomy, and it was not until the beginning of the last century that distinct teachers were appointed in the universities for imparting instruction in that subject. A chair of anatomy was founded in Cambridge in 1707; one in Glasgow in 1718. In Dublin an anatomical theatre was built in the University in 1711, in which lectures on anatomy, chemistry, and botany were delivered, and in 1784 these lectureships were converted into professorships.

Efforts had been made during the last ten years of the seventeenth century by the Incorporation of Surgeons of this city to provide for their members and apprentices instruction in anatomy, and an anatomical theatre was built for that purpose; but it does not seem that the lectures and demonstrations were delivered regularly, and the conditions under which the instruction was imparted threw many difficulties in the way.

In 1705 the Town Council of Edinburgh, then the patrons of the University, allotted to Robert Elliot, surgeon, who held the office of public dissector of anatomy to the Incorporation of Surgeons, the sum of £15 of yearly salary, as an encouragement to pursue the teaching of anatomy. This is the first record of the introduction of the study of anatomy into the system of teaching in this University. In 1708 the Town Council appointed Adam Drummond "to be conjunct professor of anatomy with Robert Elliot, chirurgion apothecary and present professor thereof." It is doubtful, however, if either of these professors, or John McGill, who succeeded Elliot in 1716, did more than give occasional demonstrations on the anatomy of the human body. The commencement of the medical school as a definite organisation for affording systematic instruction in anatomy and in other departments of medical study, dates undoubtedly from the appointment by the Town Council in 1720 of Alexander Monro, *primus*, to the chair of anatomy in this University. In the beginning of the winter of that year he delivered a regular course of lectures on anatomy and surgery, and during the same session Monro induced Dr. Charles Alston to lecture on *materia medica* and botany. In 1726 Drs. Plummer and Innes were appointed to the chair of chemistry, and Drs. St. Clair and Rutherford to those of the practice of physic and the institutes of medicine; and immediately after their appointment all these gentlemen began to deliver regular courses of lectures. The medical school was now very completely organised according to the requirements of the time, so far as regarded provision for the delivery of lectures on the chief branches of a medical education. But an infirmary for the practical study of disease was still wanted to give completeness to the system of instruction. A scheme was therefore proposed by Monro's father and the members of the Royal Colleges of Physicians and Surgeons, for raising a subscription and building a hospital for the reception of the sick. Monro himself, in conjunction with the Lord Provost Drummond, actively promoted the work, and in a short time a hospital was provided. How thoroughly these founders of our medical school had grasped what was essential in a training for the practice of our profession is shown by the way in which they utilised the infirmary after it was erected; for Monro frequently gave lectures on the surgical cases, whilst Rutherford began in 1748 to deliver clinical lectures on the most remarkable medical cases in the wards.¹

Monro had been specially trained under the guidance of his father—one of the great objects of whose life was to develop a school of medicine in Edinburgh—to become a teacher of anatomy. His success was marked from the beginning, and gave proof of his ability as a teacher, as well as of the need that existed in Scotland for the establishment of a school of medicine. From his class-lists, now in the possession of the chair of anatomy, I find that he began with 57 students, and that the class gradually increased, until, in 1744, 150 students attended his præ-

lections. Owing to the political troubles of 1745 the class fell that year to 76, but in the following year it rose to 182, which was the maximum number it attained during his incumbency of the chair.

The seed which had been sown by the founders of the school fell upon good ground, and under the fostering care of Alexander Monro, *secundus*, and of his able colleagues, Robert Whytt, William Cullen, Joseph Black, John and James Gregory, and Andrew Duncan, it became a stately tree. A great increase took place in the number of students attending the medical classes in the latter half of the last century, who were attracted in large numbers from England, Ireland, and the Colonies, and in consequence of that increase the buildings of the University with which you are all familiar on the South Bridge, were projected, and in the course of time constructed. From the records of the anatomical class I find that the pupils of the second Monro, whose reputation as a teacher and investigator was even more renowned than that of his father, numbered for many years between 300 and 400, and that in 1783, 436 students attended his class.

In the earlier half of the present century the school as a whole continued to prosper, although, from the circumstances of the anatomical chair, the number of pupils in attendance on that class was much diminished. With the appointment in 1846 of John Goodsir, one of the most philosophical of modern anatomists, to the chair of anatomy, an important revival took place in the character of the teaching, the class once more assumed a foremost position in the school, the students greatly increased in numbers, and in 1852-53 mustered 368 pupils.

The appointment of a Royal Commission in 1858, under the presidency of one of the most sagacious of living Scotchmen, the present Chancellor of our University, effected a great change in the constitution of the University and in the regulations for graduation. By the ordinances of that commission a preliminary examination in arts for medical students was rendered compulsory, the board of examiners was organised on a wider and better basis, the degrees of M.B. and C.M. were instituted, and the degree of Doctor of Medicine was ordered not to be given until candidates had reached the age of twenty-four years.

The immediate effect of these ordinances was undoubtedly to diminish the total number of students of medicine frequenting the University, which fell in 1868-69 as low as 403. For it required a few years to bring the education imparted in the schools into harmony with the requirements of the preliminary examination. When this was, however, established students once more began to flock to Edinburgh, and from 1869 to the present date a yearly increase has been going on, not by slow degrees but by leaps and by bounds, until in the last academic year the total number of students of medicine reached 1253. In the general prosperity of the school the class of anatomy has participated, for 679 students were enrolled as members of it during the last winter session. Under the influence of these ordinances the prestige of our medical degrees has been very materially increased. By the institution of the preliminary examination, conducted by the same examiners as for the degree in arts, the entrance of illiterate persons has been prevented, and the tone of our students and graduates has been elevated. By the widening of the professional examining board and the admission of a number of non-professorial examiners equal to that of the professorial staff, the character of the examination has been raised. By the power given to the *Senatus* to administer the affairs of the University numerous improvements and additions have been made to the educational arrangements.

It may not be without interest to inquire how it was that, whilst during the last century important schools of medicine arose as parts of the educational machinery of the universities in Edinburgh, Glasgow, and Dublin, yet that no corresponding development occurred in the great English universities in Oxford and Cambridge.

In a presidential address delivered in August last at the annual meeting of the British Medical Association in Cambridge, Professor Humphry related the circumstances which in his judgment repressed the formation of medical schools in the two ancient English universities. He placed in the front rank of antagonistic causes the proximity of Oxford and Cambridge to London, which from its greater wealth and the more abundant opportunities that it afforded for study attracted the practitioners, teachers, and students of medicine; also the influence exercised by the powerful com-

¹ The authorities for this summary of the rise of the Edinburgh School of Medicine are the Memoir of Alexander Monro, *primus*, prefixed to his collected writings; the Histories of the University of Edinburgh, by Bower and Dalziel; Dr. Gairdner's Historical Sketch of the Royal College of Surgeons of Edinburgh, and his Sketch of the Early History of the Medical Profession in Edinburgh; and most fully in Professor Struthers's Historical Sketch of the Edinburgh Anatomical School.

peting Corporations of Physicians and Surgeons in the metropolis, which had power to grant licences to practise.

But in connexion with this argument I would point out that powerful medical and surgical corporations were not and are not confined to London, but that similar institutions, exercising large local influence, possessing many privileges, having the power of licensing, and up to a recent period even a monopoly of granting licences to practise in certain districts, were and had been for many years established in Dublin, Edinburgh, and Glasgow, and yet the medical schools connected with the universities in those cities grew and flourished.

One cannot doubt, if there had been a university in London when the national demand for an improved medical education arose in the beginning of the last century, that in England, as in Scotland and Ireland, competent professors would have been appointed in it as parts of its educational machinery, and a medical school of influence and renown would have been created. The scientific and practical training of the medical practitioners in England would not have been left to the private enterprise of the physicians and surgeons attached to the London hospitals, but would have centred in the university, whilst the hospitals would have been adjuncts to it as places of clinical study.

England suffered therefore, as regards medical education, a great loss from not having had a metropolitan university during the last century. And when one was founded during the present century, it was established on so peculiar and exceptional a basis—as a mere examining board—that it provided no educational training, and has exercised therefore little if any influence upon the education of the great body of practitioners. Hence there has arisen in the minds of many Englishmen a conception of the relations of the universities to medical education, and to the medical practitioner, which to us in Scotland seems quite erroneous. They look upon a university training as not intended for the profession generally, but as an especial privilege of the select few. We, on the other hand, hold that the more you bring the great body of the profession into relation with the thought and culture and scientific methods of our universities, the wider and more precise will be the basis on which to found rational methods of practice, and the more will our profession advance in the estimation of the public.

But other causes than proximity to a great metropolis and the influence of powerful medical corporations tended to repress during the last century the development of medical schools in the two ancient English universities. In them much longer than in Scotland did the idea prevail that their primary function was to train ecclesiastics. The system of each of these universities, which practically gave the control over the education, not to a body of professors, but into the hands of the fellows and tutors of the different colleges; the semi-monastic life imposed on the resident fellows, so many of whom were required to enter into holy orders; the valuable endowments attached to the different wealthy colleges conferred as prizes on those who entered the Church as a profession—all tended to keep the system of education in a particular groove, and to check its expansion. But, further, the imposition of a religious test, both on teacher and student; the necessity of having to reside in a college, with its attendant expenses; the absence, in England, of such a complete set of parochial schools as prevailed in Scotland, in which the child of the peasant could obtain the rudiments at least, and in many schools much more than the rudiments, of a training in classics and mathematics—excluded from the English universities a large body of the nation, and restricted their privileges to members of the Established Church and to the wealthier classes of the community. There can be no doubt that the expense and other difficulties which beset the path of so many young Englishmen in obtaining a university training and degree in medicine in the southern division of the island, sent them across the border to Scotland, and contributed in no small degree to the prosperity of the Edinburgh school of medicine.

It required the freer light and air, and the wider conception of the relations of a university to the life of a nation, engendered by the progress of knowledge during the present century, to break down the long existing exclusive system of the English universities, and to bring them into closer contact and sympathy with modern thought and work. During the last twenty-five years a considerable addition has been made to their staffs of professors, and educational duties have been required of them; tests have been abolished; a non-collegiate system of residence has been sanctioned;

endowments have been thrown open to a wider range of persons; museums, laboratories, and other means and appliances for affording instruction in the sciences have been constructed and obtained; the curriculum for the degree of Bachelor of Arts has been remodelled, and a much greater latitude as regards the subjects both of education and examination has been granted to candidates. Medicine and the sciences on which it is founded have shared in these improvements. Unquestionably the small population of the districts in which Oxford and Cambridge are situated, and their proximity to London, will always throw impediments in the way of a development of the practical and clinical parts of a medical education; but the undergraduates of these universities who intend to enter on the study of our profession, have now the opportunities of being trained in the fundamental sciences on which the practice of medicine is, or ought to be, based, and in Cambridge provision is also to some extent made for imparting a knowledge of the more advanced subjects of professional study.

(To be concluded.)

THE INFECTION OF PHTHISIS.

By REGINALD E. THOMPSON, M.D., F.R.C.P.

THERE are many questions in medicine which have long engaged the attention of the profession and caused such a division of opinion that authorities will be found ranged in two opposite camps in equal numbers, holding diametrically different views regarding them; and among such open questions the contagiousness of phthisis may be classed as one which has been affirmed by some and denied by others at all times of the world's history.

It is indeed a very old question, for it was advanced by Aristotle and answered in the affirmative by him and Morton, and many others; but authorities of equal weight and number can readily be found who have taken the other side, and given a direct negative to such a possibility.

Upon this subject opinion still remains strangely hesitating, more especially in temperate climates; and it is curious to note how far more positive are the views of those who have made their observation in warm climates—a difference of opinion which requires some explanation, and may perhaps lead to some further elucidation of the problem.

In Italy quarantine regulations used to be enforced regarding deaths from phthisis, and, acting upon such regulations, innkeepers and others have been wont to levy a heavy tax for cleansing and disinfecting rooms where the consumptive patient has been; while in India, if my information be correct, such patients are considered almost as dangerous as lepers used to be under the Mosaic sanitary laws, popular opinion compelling even the washing of cups and platters that have been handled by them.

The arguments brought forward to support the idea that phthisis is contagious have been derived mainly from facts showing that individuals in intimate relation with each other have been successively attacked with phthisis. But such evidence, which simply depends upon a numerical probability, cannot be considered a satisfactory way of solving the problem, for the few cases which can be brought forward by any observer are not sufficient to remove the chance of mere coincidence for so common a disease as phthisis, which it must be presumed will be found affecting individuals in close relation to each other (e.g., husbands and wives, brothers and sisters) in succession in a certain proportion of cases. This kind of argument is not likely to be convincing. The remarkable series of cases, however, which have been published by Dr. H. Weber advance the question a step further, for it can scarcely be considered within the pale of chance that several wives of a consumptive husband should successively fall victims to pulmonary disease. But, from the experience of some years, I believe that the subject may yet be approached from a different point of view, and I would appeal not to the numbers in which pairs of individuals may be successively attacked by disease, but to special features, clinical and pathological, which mark the infective disease, and which distinguish the transmitted disease from ordinary forms of phthisis.

The proposition which I shall venture to advance is this:

That infective phthisis (by which term may be designated that form of disease which results from the infection of phthisis) is a disease which has peculiar symptoms and signs of its own serving to distinguish it from phthisis, and approximating closely to those of a pyogenic or infective pneumonia.

If this proposition can be established, then I think it must be admitted that the question of the possible communication of phthisis will have received a more satisfactory answer than when arguments are drawn from the numerical point of view. Of late years experiments on animals have been largely appealed to with regard to the nature of phthisis and tubercle, but inasmuch as I believe that the artificial disease differs materially from phthisis as it appears in man, I have no intention of pressing the results of such experiments into the argument, nor of appealing to them, although I could do so with some effect, to help me in a difficult question.

The observations upon which the following conclusions are based extend over a period of ten years, and are derived from a total of twenty-five thousand patients: the series of cases to which special attention has been directed are those of wives infected by husbands, inasmuch as the possibility of error arising from blood relationship is hereby avoided, and the association of the nursing wife with the sick husband is so constant and intimate that if phthisis can be communicated it must be looked for in such instances.

Fifteen well-marked examples of this kind have come under notice out of something like fifteen thousand cases of phthisis, so that the proportion of infective cases may be reckoned as not less (probably a little more) than one per mille; hence it is easy to understand why observers, with a small number of patients, should disbelieve the possibility of contagion. I have, however, rejected from the series cases which might have been included, but in which the symptoms were not so acute and distinctive, and which may eventually prove to be chronic or subacute forms of that disease, which was manifested in an acute form in the fifteen selected cases.

Grouping all the cases together and analysing the symptoms and signs which characterise them, I would advance the following conditions as serving to identify the disease and to distinguish it from ordinary forms of phthisis.

1. A slight hacking cough appears to be the earliest symptom of infection, and I would suggest that this is an indication of the irritation of the air-passages, due to the introduction of the *matrices morbi* through their agency.
2. Symptoms of constitutional poisoning are at once shown by the rapid emaciation which is noticed by the patient in a very early stage of the disease.
3. As the disease progresses, rigors, accompanied by night sweats and pyrexia, occur at frequent intervals.
4. Later on the cough returns, considerably aggravated, and sputa are from time to time tinged with blood. Hæmoptysis to a small amount occurs, but is not frequently repeated.
5. The physical signs are usually bilateral, although not necessarily exactly uniform on both sides.
6. The pulmonary disease is disproportionate to the amount of constitutional disturbance, and is not sufficient to account for the extreme emaciation of the patient.
7. The physiognomy of the patient is not that of phthisis, and the colour of the skin is of a dull sallow hue, far different from the pallor which is so marked a feature in the consumptive patient.

With regard to the character of the physical signs, even after the patient has been ill for many months I have generally not been able to make out more than a few subcrepitant or crepitant râles, diffused, and of a somewhat peculiar character, in both infra-clavicular regions; but one lung may be attacked before the other, and, consequently, in some cases, and late in the disease, a cavity may form.

It is difficult by a mere description on paper to enforce differences which mark the features of a particular disease with the same impressive distinction with which clinical experience stamps them, but I will make the attempt in the following case, which may be taken as a fair sample of the disease under consideration:—

A widow, aged twenty-seven, presented herself for examination under the following circumstances: There was no history of consumption in her family, nor could I elicit any facts to show that she had been delicate or liable to cough before. Her husband had suffered from symptoms of rapid phthisis (cough, sweats, and diarrhoea) some months before marriage, and, finally, died of phthisis nine months after marriage.

During these nine months she was his constant companion and only nurse, and although warned of the danger, had slept with her husband up to the day of his death. There was no offspring from the marriage. Three months after marriage she began to suffer from a slight hacking cough (which she was quite unable to trace to cold), accompanied by rapid loss of flesh. The constitutional symptoms became aggravated; the emaciation speedily increased, and was accompanied by a succession of rigors with night sweats of a marked character. These were associated with dull aching pains all over the body. Six weeks after the death of the husband the cough returned with considerable exacerbation. Much expectoration, occasionally streaked with blood. Slight hæmoptysis was noticed. With these symptoms there was a return of night sweats, and subsequently diarrhoea set in.

When she presented herself for advice her illness had lasted sixteen months (her husband having been dead thirteen months). She was extremely emaciated and worn, her face thin and drawn; her complexion sallow, of a dull ochry hue, and her aspect was far more like a patient suffering from pyæmia than from pulmonary phthisis; the skin was hot and dry, and the pulse rapid (124). The following were the physical signs. Her chest was well formed, but thin; there was no local retraction or depression. Diminished resonance of percussion was found under both clavicles from the first to the third ribs in front, and the same sign was found over the supra-scapular fossæ. Auscultation showed the presence of some diffused, viscid, crepitant râles, confined to the end of inspiration from the first to the third ribs, in front, on the right side; fewer in front on the left, but harsh respiratory murmur and subcrepitant râles over the left supra-scapular fossa.

If it had not been for previous experience of similar cases, and for the limited pulmonary disease indicated by the above signs, I should have almost despaired of a favourable termination to the case, so great was her emaciation and want of vigour, more especially as she had for some time been unable to take cod-liver oil, and was at the time under most unfavourable conditions of climate. However, she improved with the use of iron and maltine; she gained flesh. The physical signs cleared away, and in four months she was restored to health; and when I last heard of her she continued well, and was about to return to America, the home of her husband's relations.

The other cases which I have in my note-book, although not so complete as this, have the same distinguishing features, and point to the same conclusion, that the disease is not a true phthisis, but in all points resembles a condition of pyogenic pneumonia or pyæmia.

But it will naturally be asked, What pathological evidence can be adduced in support of these surmises with regard to the nature of the disease? The following case, in which the symptoms and signs during life were made by an independent observer, and closely coincide with those of the case I have already detailed, is the only one to which I can appeal, but the pathological conditions are very decided, and quite distinct from those of phthisis. The patient was under the care of Dr. Williams, and I am indebted to his courtesy for permission to use the case.

A widow, aged thirty-nine, was admitted into hospital in August, 1878, with the following history and symptoms. No history of inherited predisposition to phthisis in any of her family could be obtained. Her husband had suffered from phthisis, and after a family of eight children (one of whom had died of phthisis, the others being all reported phthisical) had been born to them he died of that disease; the exact date was not given. Sixteen months before admission the woman began to suffer from a hacking cough (not traced to cold) and emaciation of a marked character. After eleven months' illness she had a slight attack of hæmoptysis, blood being mixed with the sputum; diarrhoea followed, and during the time she was in the hospital she suffered from rigors and night sweats.

The physical signs noted were diffused crepitation over both lungs, most marked at the lower half anteriorly.

In October she was attacked with pleurisy, and in November the right lung broke down, and a cavity formed. Three weeks before death she had phlebitis, with an erysipelatous blush over both forearms.

The post-mortem examination which I made at the end of December, 1878, showed a very peculiar condition of things. The left lung was adherent at the upper half, and the lobules were found stuffed with a caseiform material, the

bronchioles being pigmented at their bifurcation, producing a peculiar appearance, as if a big V was stamped or painted in the middle of each lobule. The lower portion of the lung was in an earlier stage of disease—a hard congestion of a patchy character being presented to view, resembling an infective pneumonia. The right lung was completely adherent except at a space at the lower anterior portion, where there was a small collection of recently formed pus. The condition of the lung was similar to that of the left, but the disease had progressed farther, and the caseiform material had broken down, leaving a cavity of the size of a Maltese orange. At first I could find no tubercle, but on careful search two racemose groups of recent tubercle were found below and in close proximity to the cavity. The spleen was pale, small, soft, and diffident, and resembled the pyæmic spleen. The lungs were carefully examined microscopically; and, naturally anxious to have my views corroborated, I submitted sections to Dr. Klein, who was good enough to examine them, and expressed the opinion that they indicated an infective pneumonia.

I must remark with regard to this case that I have never come across a case of ordinary phthisis which at all resembled it, and although I have been on the alert for indications regarding the nature of the clinical symptoms which appear to mark cases of acute infection, I have not had an opportunity of investigating any other case of the kind. If further observation should corroborate this evidence, it would, I think, lead to the conclusion that phthisis in its power of communicating disease must be looked upon not as a zymotic disease capable of sowing itself, and reproducing the same form of disease, with identical symptoms and signs, but rather as an ulcerative process capable of giving rise to pyæmia. This view of the infection of phthisis would induce less terror than the notion that it was a contagious disease in the generally accepted view of the term, and prevention might be expected from simple measures of hygiene, especially free ventilation of the patient's room. Such means might reduce the risk of infection to a minimum without preventing that assiduous care and attention which alleviates and soothes the last days of the dying invalid, and the devoted wife need not fall a victim to her duty and ministering care.

It may perhaps be necessary for me to state that cases come under observation with a history of possible infection of which the symptoms are less marked and intense, and in which the pulmonary disease is not distinctive enough to constitute a diagnosis. How far such cases may be classed with those acute and intense forms of disease which I have attempted to describe, and how nearly they may resemble ordinary phthisis, is a matter which will have to be decided by the features of each individual case. I wish especially to guard against the supposition that in all cases of infection the form and progress of the disease must assume the same strikingly marked features which appear to characterise the acute and intense form of the infective disease.

REMARKS ON STRICTURE OF THE URETHRA IN CONNEXION WITH INTERNAL URETHROTOMY.

By SURGEON-MAJOR T. J. MCGANN, I.M.D.,
CIVIL SURGEON, MYSORE.

THE gist of my communication lies in the fact that in several bad cases of stricture which have come under my care recently, I have at once, without any previous efforts to treat them by gradual dilatation, resorted to internal urethrotomy, and with very satisfactory results so far. The instrument I have used has been that of Mr. Teevan, which was described by him in March, 1878.

The natives of India are, as a rule, very reluctant to seek treatment for stricture, and will go on without such as long as they can pass urine, even in a very small stream, or squeeze it out drop by drop, and so relieve themselves for the time; and hence cases of extravasation, with sloughing of scrotum and perineum, are not uncommon, and less so still are bad strictures. It is, therefore, with the worst class of cases that one has, as a rule, to deal with, and even these rarely come to hospital until actual retention has occurred, with probably an over-distended bladder and rupture of the

urethra imminent, so that prompt measures are demanded. In Indian hospitals the supply of catheters and bougies is limited, and as they rapidly deteriorate from climatic causes, and become inefficient after very little use, and as it is the small sizes which are most frequently used, surgeons often find themselves with nothing but large ones in hand. I have, therefore, on occasions felt anything but pleasure at being called on to treat an urgent case, with perhaps a bladder distended to the umbilicus, a tight tortuous stricture, impassable to any instrument within my reach or obtainable in a reasonable time, aggravated, perhaps, by an indurated distorted condition of perineum. Under circumstances such as those enumerated, and with no very small instruments available, it will be readily conceived that puncture of the bladder has had frequently to be resorted to to relieve present urgent symptoms, and as a preliminary to other treatment; and although I have hitherto found puncture per rectum a perfectly safe operation, it will be admitted that it is undesirable to have recourse to it as a routine measure in every bad case of stricture that comes under treatment, albeit it gives time and admits of good results being achieved afterwards.

About a year ago I procured, through my friend Dr. Macgrath of Bayswater, Mr. Teevan's urethrotome, for a bad stricture complicated with numerous fistulae, which, after much trouble, I dilated up to No. 11, English, but which contracted again very rapidly, notwithstanding the occasional introduction of the full rigid instrument by the patient, and two of the openings never completely healed. After the free use of the urethrotome in this case the fistulous openings healed, and there was no tendency to further contraction.

The following are the cases previously alluded to in which urethrotomy was performed (from notes by Mr. Apothecary Costello):—

CASE 1.—Beeram Saib, Mahomedan, age thirty-five, admitted to hospital 2nd April, 1880, with tight organic stricture of long standing. Urine can only be passed in drops with much straining, bladder greatly distended, and rupture threatening. No instrument can be passed through the stricture, which is situated in the subpubic region; and after all efforts at catheterism failed, the bladder was punctured per rectum, and a cannula and tube tied in. For some days subsequently trials were made to pass No. 1 catheter or bougie, but without success. On the 10th the conducting bougie of Mr. Teevan's urethrotome having been passed through the stricture with a little trouble, the staff was screwed on, and it was made to follow the bougie by means of moderate pressure into the bladder. The pressure was only necessary to get the thickened part, or point of junction between the bougie and staff, through the stricture, and that being passed, the shaft of the staff passed readily enough. The sheathed knife was now adjusted, and a small incision having been made at the meatus to allow it to pass, it was passed down to the stricture, and the blade being protruded this was thoroughly divided. To ascertain that this was done, the blade was retracted after resistance had ceased, and the sheath pushed further on, but no further obstruction being encountered the instrument was withdrawn, and a full rigid catheter passed. The man was discharged with a urethra of the full calibre on the 25th April, the rectal wound having healed. Mr. Teevan conditions that urine should flow through the groove in the staff before operation, but in this case it was not, as the bladder was kept empty by means of the cannula in the rectum. There was, however, no difficulty in satisfying oneself that the instrument was in the bladder, both because of the direction and of the facility with which its point moved about in the viscus, &c. There was scarcely any bleeding from the operation.

CASE 2.—Buden Saib, Mahomedan, age fifty, admitted April 8th, 1880. Old-standing stricture; has fistulous openings in perineum. No. 1 catheter passed after much difficulty. Was treated by catheterism in Shimoga two years ago, when urethra was dilated fully, but it began to contract soon after. Urethrotomy performed on April 8th; very slight bleeding; No. 11 English catheter passed readily afterwards. Fistulae closed; No. 12 catheter passes readily. Discharged April 18th, with a large instrument to pass occasionally for himself.

CASE 3.—Bullaree, Hindu, age forty-five, admitted June 2nd, 1880, under Dr. P. H. Benson's care. Urine passing in drops; no catheter would pass; several fistulae in perineum. Urethrotomy performed same day; no bleeding. Discharged with urethra of full calibre on June 20th, No. 12 catheter passing easily, and fistulae closed.

CASE 4.—J. W.—, European, age thirty, admitted under Dr. Benson's care on July 10th, 1880. Had been treated by gradual dilatation some time ago, but stricture recurred, and urine passes now in a minute stream. Fistulous opening in perineum. No. 4 catheter à boulie passed with difficulty. Catheter withdrawn afterwards, and there was so much difficulty in reintroducing it, that Mr. Teevan's instrument was used, and the stricture cut on the 13th. The strictured portion not having been completely divided, I used the urethrotome again on Aug. 1st, and after that there was no further difficulty. No. 12 English catheter passed freely, and the man was discharged on the 22nd, with a full-sized instrument given him to pass occasionally, the fistula having closed some time previously—viz., soon after the urethrotomy.

In the last case there was a little fever after the operation, but not more than followed catheterism previously, and it was readily controlled by quinine and opium. I also noticed that in No. 4 a well-curved catheter with a stilet in it, so as to direct its point along the roof of the urethra, passed more readily than a soft straight catheter or bougie à boulie, the explanation of which I assumed was, that the latter became engaged in the old fistulous orifice or annular portion of the stricture, whereas the former glided over or through the gap made by the knife, and which was ultimately filled up with the "cicatrical splice," which remained less prominent than the indurated part in the unincised portion.

Four cases are of course too few to draw any conclusions from, but if, according to the highest authorities, organic stricture is not curable, strictly speaking—i. e., the indurated structures giving rise to it are never completely removed, and the urethral canal restored to its original healthy state, and there is a liability to its recurrence, and if it is an "operation perfectly safe and easy to perform," then it would seem to me that internal urethrotomy is the operation for severe and obstinate cases, if not even for milder ones where, as in India, the surgeon may lack the necessary instruments occasionally, or the patients be unreasonable and disinclined to submit to lengthened treatment, and want to leave before the "gradual dilatation" process has more than half done its work. At all events I now feel myself, whether rightly or wrongly, that I can attack most cases of stricture and treat them efficiently by internal urethrotomy, without having the prospect of having to puncture the bladder before my eyes as previously whenever I failed with catheterism; that is, of course, wherever the filiform bougie of Mr. Teevan's instrument will pass, and the percentage of cases where it ought to fail is, I think, very small.

THE CHLOROFORM DEATH-BILL FOR TWELVE MONTHS.¹

By ERNEST H. JACOB, M.D.,

PHYSICIAN TO THE LEEDS DISPENSARY AND THE LEEDS FEVER HOSPITAL.

IN a previous communication² I reviewed the great change that had occurred during the past few years in the substitution of ether for chloroform in surgical practice. In 1876 a return from the anæsthetists of the London and other large hospitals revealed the fact that, save for the aged and infants, ether had taken the place of chloroform in nearly all our great surgical centres, and not only this, but that the change was felt by the officers in charge of the administration to be one greatly to the advantage of the patients as regards their subsequent condition, as well as the mere avoidance of death while under the influence of the drug.

And yet, during the past twelve months, no less than twenty-five deaths have occurred from chloroform—I ought rather to say, have been recorded, for, no doubt, many occur which it is convenient and possible to say nothing about. Of these twenty-five, seventeen only occurred in Great Britain, fifteen being in hospital, and eight in private practice. The operations were mostly of the simplest kind. Dressing wounded fingers or toes, three; necrosis, four; extraction of teeth, two; amputation of the breast and lithotripsy, one

each; and one for applying a splint to a child's leg. The deaths appear to have occurred in the usual way from sudden syncope. As regards the post-mortem appearances, which are noted in fourteen cases, in five all organs were perfectly healthy. In eight only the heart was more or less "fatty" or "flabby," and in one there was emphysema of the lungs.

As regards locality, two deaths took place in the Edinburgh Infirmary, where, I believe, ether is not in use; two in the London Hospital, where ether is extensively used; and three in Liverpool.

During this period five deaths from other anæsthetics have been recorded. One each from ethylene dichloride and ethyl dibromide, and three from ether. Of the latter two occurred in America, one during extraction of teeth, no particulars being given, and one during an operation for hip disease, the patient suffering from valvular disease of the heart. The remaining case, the only one in England, was that recently reported by Mr. Hartley, which could not be said to be due to the anæsthetic, as the patient was almost in *articulo* from intestinal obstruction when the operation was commenced.

It can hardly be too strongly urged that the fatality of an anæsthetic cannot be deduced from the experience of one observer. The cases must amount to tens of thousands. During the past few years, however, there has been no lack of material for statistical inquiry, and the result is to be read in the facts I have stated.

A death from an anæsthetic administered for a trivial operation cannot be regarded as anything but a serious calamity. It is not for me to say that a grave irresponsibility rests on the surgeon who employs chloroform when a safer anæsthetic is available, but I think it cannot be long before the voice of the profession (if not of the public, as in America) demands some explanation for the use of an agent whose victims are numbered by hundreds.

Leeds.

ABSTRACT OF INTRODUCTORY ADDRESS,

Delivered at the Opening of the Winter Session of the School of Medicine, Surgeons' Hall, Edinburgh.

By DR. FRANCIS W. MOINET.

GENTLEMEN,—It has devolved upon me in the name of your teachers to address to you this morning a few words of welcome and encouragement on the occasion of the commencement of the medical session. We welcome you as fellow students in a noble profession, which has for its aim the prevention and relief of human suffering, in striving to accomplish which you will find ample reward for all the labours of mind and body you may expend upon it. I take it for granted, gentlemen, you have chosen your profession thoughtfully for the love of it, because unless you feel your hearts are in the work you will neither do justice to yourselves nor to your work. It is one which should thoroughly commend itself to you in its aim and endeavours apart from all extrinsic questions as mere pecuniary reward. Now is the time to think of your work only, and how best you are to prepare yourselves for its responsible duties. In thinking over what I would address you upon this morning, it appeared to me that our time would be most profitably occupied in directing your attention briefly to what I consider is the right spirit in which you should prosecute your studies. This I feel can best be done by trying to impress upon you the importance of entertaining a high opinion of your profession and a clear idea of its responsibilities; the first will make you careful to do nothing to tarnish its reputation, and the second should stimulate you in your work, so that you will do credit to yourselves and to the profession for which you are now going to prepare yourselves, and so maintain if not raise the estimation in which it is held by the public, and increase its power of usefulness. In treating your patients you should be satisfied that you have used all the possible means which science and experience have gathered for our use. This is the responsibility which you undertake when you go out into the world to practise your profession, and which, if properly realised by you now, will be the best stimulus to you to work hard as students, by

¹ Read before the Leeds and West Riding Medico-Chirurgical Society.

² On Ether as an Anæsthetic, THE LANCET, vol. ii. 1879, p. 539.

doing which you can alone hope to bear it with comfort to yourselves and benefit to the public.

Equal attention should be given to all subjects of study; they are so intimately connected with each other, and with the practical application of our knowledge in the treatment of diseases, that ignorance in any one of them will sure to be a cause of future difficulty. The trust which a patient places in us should make us careful to be honest to avoid any semblance of quackery. When a medical man allows the thought of the fee to come before other considerations he is not to be trusted as a worthy disciple of the healing art. In this way we will render ourselves more worthy of the confidence which the public place in us—a confidence which is of mutual benefit,—it encourages us in our efforts to do our best to repay them in receiving the results of these efforts, when they apply to us in their need. To do everything in our power to spread abroad a knowledge of the true means to prevent or arrest the spread of disease is, I hold, the duty of every medical man. If our professional advice was more frequently sought for as to the daily mode of life of our patients, there would be fewer diseases to treat, and our attention could then be more profitably directed to prevent rather than cure disease, which, if not easier, would be more beneficial to the community. I would also advise you in ordering alcoholic stimulants to be careful to order their discontinuance when satisfied that they are no longer required to meet the exigencies of the case, so that they could not advance as an excuse of the vicious indulgence the doctor's order. The same may be said of the use of narcotics, such as opium, chloral, or morphia; you must also remember that, as medical men, you must often necessarily be the confidant of your patient both in regard to personal and family matters. Not only the health, but often the happiness, of families may depend on your discretion. Cultivate, therefore, the habit of reticence about your patients; even in professional circles cases should only be mentioned anonymously. You must also do as much as lies in your power to advance the science of medicine. Bear in mind now that you are entering upon your life's work, and one which will demand all your energies, especially a sound mind in a sound body. Do not cram; work regularly, and you will thus economise both time and labour; your lectures will interest instead of wearying you, and the facts will be impressed on your memory, so that it will neither fail you at the examination table nor the patient's bedside. Do not during your student career devote your time to any especial subject; time enough for that when you have obtained your diploma. To be a good specialist you should be strong all round. Disease of special organs has such a close dependence upon constitutional conditions that it is impossible to separate the study of the part from the whole if you are to be successful in your treatment. These hints I offer to you as a help in going through your college career. And I give you this encouragement, that if you put your hearts in the work now it will surely become a pleasure, and when once that is the case you need not fear examinations, responsibilities, the attainment of professional reputation, and a fair amount of worldly success.

CASE OF POISONING BY PARAFFINE.

By HORACE ELLIOTT, M.R.C.S.,

LATE HOUSE-PHYSICIAN AND HOUSE-SURGEON, WESTMINSTER HOSPITAL.

A SHORT time back a child two years of age was brought to me by its mother, who stated that the child had been sent to a shop with an elder sister to purchase some paraffine. The paraffine was put into a tin can, and given to the younger child to carry. As they were going home they stopped to look at a street row; while doing so the younger child removed the cork, and drank some of the paraffine.

The child was seen about twenty minutes afterwards, and was found to be in a state of semi-collapse, being very pale; the surface of the body was cold and clammy; the pulse small and feeble; the pupils were widely dilated, but acted slightly to the light from a candle. The breath smelt strongly of paraffine. The little patient was dazed and very drowsy, and could only be kept awake with difficulty. Did not cry. Vomited slightly before I saw it, and again soon afterwards. Emetics were administered, which only acted slightly, the vomited matter smelling very

strongly of paraffine. The child was not allowed to go to sleep, and about two hours afterwards it began to rally; the surface of the body becoming warmer, and the pulse more frequent; the patient cried; there was no diarrhoea. Next morning the child was quite well, the pupils being normal, and the breath smelling slightly of paraffine. I was unable to ascertain the quantity swallowed, owing to its being in a tin can.

From the above notes, it will be seen that the symptoms somewhat resembled those of poisoning by belladonna.

Bristol.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla enim est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

KING'S COLLEGE HOSPITAL.

LEFT-SIDED EPILEPTIC HEMIPLEGIA AND APHASIA;
RECOVERY.

(Under the care of Dr. FERRIER.)

FOR the following notes we are indebted to Mr. P. H. Emerson, house-physician.

A. W—, aged twenty-seven, was admitted into the Todd ward on Monday, June 21st last, and transferred to Dr. Ferrier's care. All the following facts were obtained by questioning the patient, who comprehended and wrote the answers himself on a slate. His father, mother, and six brothers and sisters were all alive and healthy. He himself was married and had four children healthy, except the eldest daughter, aged six, who had had two fits, which from the description were apparently epileptic; otherwise she, too, was healthy. He had been a whitesmith for nine years, over and above serving an apprenticeship of five years. He was a right-handed man.

About 2.30 P.M. on Nov. 20th, 1869, he fell from a scaffold twenty-five feet high. In falling he struck a "padlock" with the left arm and thigh, and was so turned over that on reaching the ground he fell on his head. He was picked up insensible, and remained so until the next morning. From this fall he said he received a severe cut in the head, parallel with the middle line half an inch to the right, and extending from the level of the hair in front to the occipital protuberance behind. Six weeks after this he had his first fit (December, 1869). He had a second fall from a scaffold on Feb. 20th, 1870, followed in twenty minutes by his second fit. Altogether he had had eighteen fits. He remembered fits on July 15th and 23rd, 1875; one in December, 1879; three on March 23rd; one on June 5th, and one on June 9th, 1880. He could not remember the exact dates of others. The last two fits were the nearest together. On Nov. 30th, 1877, a piece of steel flew off from his chisel into his left eye, which led to its excision one week before Christmas, 1878. He had had lead colic three times in 1878 to 1879. Twice he had a sore-throat, but denied having had syphilis. Never had any other illness.

All the fits had been similar. Aura, he said, begins in the left hand with involuntary semi-closure and opening of hand, followed in about half an hour by pain in the left leg. About half an hour before the fit he feels a pain round abdomen, which creeps upwards as far as the larynx in front to a level with the third cervical vertebra behind, he then gets twitchings in the left side of his face, and about ten minutes before the fit these symptoms spread to the other side of the body. He is then seized with vertigo, and straightway falls unconscious. He falls on his face, foams at the mouth, bites his tongue, and struggles violently. The fit lasts from half to one hour. On recovering he feels too weak to stand, and usually rests for about one hour. After the fit he is unable to work again for a week. He stated that he has the aura before each fit, and has never had an aura without a fit following it, has never had more than one fit a day, and has gone a year without a fit. Since the first

fit two, he said, had come on after unusual exercise, as a long walk, lifting heavy weights, &c. Fits had occurred at home and at work; the first fit lasted forty-five minutes. They have been more severe lately. In no case had the fits been associated with the symptoms of plumbism. When he felt a fit coming on he called for wet bags for his head.

The last fit came on on June 9th, in the usual way. He was paralysed in the left arm and leg for two days after the fit. Was speechless after the fit, and had only spoken once since up to the time of admission, saying, "Fetch me the teapot." He was very violent during the fit, requiring two men to hold him, and was very excited afterwards. He was given a large dose of chloral and bromide of potassium, which quieted him. He had no difficulty in micturition or defecation. The arm got well before the leg.

On admission he had a slight scar on the forehead, to the right of the middle line, under the hair. None other to be detected. He complained of great pain in the right side of the head (parietal region, where he said the cut was received in the first fall), increased on slightest pressure or percussion. The left angle of the mouth was slightly lower than the right. There was very slight difference in action of the sides of the face. The facial sensibility was perfect. There was no paralysis whatever of the left arm, and sensibility was intact. Tendon-reflex was well marked in both knees. There was no appreciable difference between the two. When he held his legs in the horizontal position the left gave way first. Abduction and dorsal flexion were deficient in the left foot; sensibility was normal. The tongue movements were perfect; the lip movements were also perfect; he could whistle and swallow well. When asked whether he had headache he nodded assent, and when asked where he pointed to the right side of the forehead. On ophthalmic examination the retinal veins of the right eye were large, the disc pinkish, and the margin defined. With Gelée's tube he heard a watch twenty-two inches from the right ear and sixteen inches from the left. Understood perfectly questions put to him, but could not utter a single word; could not make any of the vowel sounds. He could write on a slate an intelligent reply to questions, and write names of objects shown him, as well as words spoken to him; but he was quite unable to pronounce the words. He complained chiefly of vertigo. Heart and lungs were normal. There was no blue line on the gums. Urine sp. gr. 1010, alkaline, no albumen; excess of phosphates.

On the 24th he had slept well, and taken food well. He still complained of slight vertigo. No pain; felt "strange." Was told to practise vocal sounds. Ordered ten grains of iodide of potassium, three times daily.

On the 25th, after dinner, he first uttered letters: O, R, and A, and several others. He could not articulate a single word, and soon gave up trying, as he said it caused him to perspire, and brought back the pain in his head. Still had slight vertigo.

On the 26th he said, "Better this morning," in a low voice. Spoke several sentences, but could not go on for reasons given above. In the evening read short extracts from a newspaper. Next day he spoke freely, but still in a low voice. Got up for a short time.

On the 28th he had slight pain in the head; but on the 29th he spoke in his natural voice. No vertigo, no headache.

On July 7th he was improving; and on the 9th, tested with dynamometer, the right hand was 110, left 100.

On 14th he was discharged, recovered.

Remarks by Dr. FERRIER.—Dr. Ferrier remarked that there could be little doubt that the symptoms in this case depended on a cortical lesion of the right hemisphere in the region of the fissure of Rolando. This was indicated (1) by the localised pain, intensified by percussion, especially over this area; (2) the occurrence of unilateral spasms, beginning always in the left hand, and followed by loss of consciousness when they became general; succeeded, after several attacks, by loss of power without loss of sensibility in the parts especially attacked by the spasms. The fact that the leg remained paralysed longer than the arm indicated a greater concentration of the distinctive effect of the lesion in the upper extremity of the ascending convolutions.

As to the etiology, the first, and considering the character of the affection, most likely hypothesis, was a syphilitic lesion of the cortex. Syphilis, however, was denied, but denial was by no means synonymous with disproof. In any case the treatment adapted for specific lesions was that most likely to be beneficial—viz., full doses of iodide of potassium, which was prescribed.

Another fact to be considered was that the patient had had one or two attacks of lead colic, and as encephalopathic affections, accompanied with intense headache and epileptiform convulsions, are not uncommon in connexion with lead poisoning, the question was whether there was any reason to suspect anything of this nature. The facts did not give much support to this hypothesis. The symptoms had never coincided with any other signs of lead poisoning, and the total absence of a blue line in the gums showed that there was no impregnation of the system with lead.

We had, however, a sufficient cause of the phenomena in the history of a severe blow on the head from a fall six weeks before the occurrence of the first epileptiform attack. The present condition of the scalp did not quite corroborate the patient's account of the severity of the injury; but even without this, the injury was no doubt sufficiently grave to have set up a superficial meningo-encephalitic irritation, for such a result may occur without marked external lesion.

An unusual feature in the case was the occurrence of absolute aphasia with left-sided hemiplegia in a right-handed man. The case was a typical instance of pure ataxic aphasia unaccompanied by amnesia or agraphia. Here only the power of utterance was abolished, and this in the most absolute manner, while words spoken and written were clearly comprehended, and the patient could think intelligently and consecutively, and express his ideas in graphic symbols.

It is not common in aphasia, with right hemiplegia, depending on affection of the left hemisphere, to have such a clear separation as in this case between word-execution, and word-memory, together with the expression of ideas in written symbols. Though there are innumerable shades in the degrees in which these faculties are respectively implicated, yet word-execution and word-memory are usually affected together, though the defects in word-memory may not be such as to appreciably impair the simpler forms of ideation. The defect, however, becomes apparent when more complex trains of thought are demanded. In this case there was a total absence of intellectual deficiency, and the patient could follow without difficulty, and give precise answers to questions involving considerable thought and discrimination. Here merely the power of word-execution was defective, and the very facts of this case, though apparently not conforming to the rule that the left hemisphere is the principal one concerned in speech, in reality confirm it. The affection of the right hemisphere caused speechlessness, probably merely by disturbance of the accustomed synergy of the hemispheres in this volitional act; whereas the complete retention of the memory of words and their associations, internal speech, and the power of expressing ideas in the graphic equivalents of articulate symbols, all indicated the greater preponderance in respect to these faculties of the sound left hemisphere.

NORTHERN HOSPITAL, LIVERPOOL.

CASE OF DISEASE OF RECTUM (SYPHILITIC?); STRICTURE; COLOTOMY; DEATH, AFTER SIX WEEKS, FROM EXHAUSTION.

(Under the care of Dr. W. MACFIE CAMPBELL.)

FOR the notes of this case we are indebted to Dr. James Allen, late house-surgeon.

Mary C—, aged forty-five, widow, was admitted Aug. 22nd, 1878. She had suffered for more than a year from some disease of the rectum; had thin watery discharge, lumpy motions, occasional constipation, varied with looseness, with slimy and bloody stools. Was treated by suppositories and dilatation. In July, 1878, had a shiver, followed by high temperature and diarrhoea. Had great abdominal and rectal pain, which subsided under poultices and opium. From that time till her admission she had several returns of this watery, foul-smelling diarrhoea.

On admission she was very much emaciated; was in constant pain, with frequent watery stools and tenesmus. The countenance was pinched and distressed. On examining the rectum by the finger a rough tubercular surface was found stretching from the sphincter to a contraction about three inches distant. The strictured portion would barely admit the point of the index-finger. A thin sanious foul discharge followed the withdrawal of the finger. She was ordered suppositories of mercurial ointment and morphia.

The pain remained constant, and the attacks of diarrhoea

and constipation were very distressing. She was evidently sinking, therefore, upon Sept. 5th, a consultation was held with a view to deciding whether colotomy should be performed. On the morning, however, the temperature was 103° 6'. She had passed a very bad night, and the operation was postponed. Next day the temperature was lower, but her general condition remained as before, the pain especially being very great, and on the day following, after consultation with Mr. Manifold and Mr. Puzey, colotomy was proceeded with under ether. Some difficulty was experienced in laying hold of the bowel owing to its emptiness and deep situation. The edges of the cut colon was secured to the skin by four silk sutures, and carbolie catgut was used to the intermediate portions. These catgut sutures were quite useless, and gave way in less than ten hours. The temperature rose the same evening to 102° 8'.

On the following day the temperature was 103° 2'. There was considerable alvine evacuation from the artificial anus, and only purulent discharge from the rectum, with great relief to the pain.

On Sept. 12th there was occasional fæcal discharge by the rectum. The artificial anus had greatly receded, some of the silk sutures having given way. Fresh silk sutures were applied.

On the 16th the wound was glazed, indolent looking, and there was absence of granulations. There was occasional fæcal discharge from the rectum, with decidedly less purulent discharge. The tongue was apthous; the tonsils ulcerated; and there were ulcers on the sides and angles of the mouth, which were relieved by touching with nitrate of silver.

On the 20th the apthous state of the mouth still continued. Glycerine and lime-water were given, with seeming benefit at first.

The further progress of the case was bad. On Oct. 2nd diarrhoea set in. On the 12th there was burrowing of pus from the wound towards the sacrum underneath the superficial muscles. Bedsores formed. There was an entire absence of any union about the wound. On Oct. 23rd she died exhausted.

Necropsy.—The most important points in the examination was some pneumonia at the apex of the right lung. The kidneys and liver were amyloid, the latter having a large white cicatrix (?) on its upper surface. The stomach and small intestines were empty, and the mucous membrane was covered by a catarrhal coat. The splenic flexure of the transverse colon was bent down abruptly in front of the descending colon, and at the level of the artificial anus it bent acutely upwards again. The descending colon was collapsed, lying along the spine. The artificial anus was in the angle of the descending loop of the transverse colon above described. Adhesions were extremely slight, and easily broken down. The mucosa of the rectum was hypertrophied. There were two strictures, both admitting the point of the forefinger—one near the anus, the other higher and out of reach from below. There was slight ulceration, but signs of cicatrisation going on. The disease seemed to be confined to the submucous tissue.

Remarks by Dr. CAMPBELL.—No history of syphilis was made out, and her character was good. The operation was undertaken for the purpose of giving rest to the inflamed rectum, and so giving time for cicatrisation to commence, when perhaps dilatation might have restored some available potency to the bowel. The complete absence of action about the wound disappointed our hopes in this direction, the patient dying from deficient vitality. The relief, however, of pain, absence of straining, and freedom from the constant discharge, gave great comfort to the patient, and made the operation so far a success. A remarkable feature in the case was the position of the transverse colon, its splenic flexure lying anterior to the descending colon at the point immediately opposite the outer edge of the quadratus lumborum, at the usual distance from the crest of the ilium.

STATISTICAL SOCIETY.—The title of the essay to which the Howard Medal will be awarded by this Society in November, 1881, is "On the Gaol Fever, from the earliest Black Assize to the last recorded Outbreak in recent times." The successful competitor will be granted the sum of £20 in addition to the medal.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Mr. A. P. Luff has obtained the open scholarship of £150, and Mr. J. Holdsworth Fisher that of £125.

PATHOLOGICAL SOCIETY OF LONDON.

Multiple Exostoses.—*Sebaceous Tumour of Leg.*—*Cancer of Lung.*—*Blood in Diabetes.*—*Tumour of Knee-joint.*—*Recurrent Epithelioma in Lung.*—*Mucous Polypus of Umbilicus.*—*Ataxic Arthropathy.*—*Hemiatrophia Facialis.*—*Telostitis.*—*Morphea.*

The ordinary meeting of the Pathological Society was held on Tuesday, Nov. 2nd, the President, J. Hutchinson, Esq., in the chair. Several cases and specimens of interest were exhibited. The President announced that fresh and living specimens of interest, and that were urgent, would be welcomed at the meetings devoted to the discussion on rickets. Drs. Moore, Barlow, Lees, and Gee, and Messrs. Holmes, Howard, and Parker, had signified their intention of taking part in the debate, and he hoped that Sir W. Jenner and Dr. Dickinson would also speak.

The secretary read a report by Messrs. Howse and Taylor on Mr. Gay's specimen of Recurrent Tumour of the Mamma. The growth consisted of three parts, which differed slightly in appearance, but were all composed of spindle-shaped cells, either without any stroma at all, or with a small amount of structureless intercellular material. It was therefore a spindle-celled sarcoma.

The PRESIDENT showed photographs of a case of Multiple Exostoses sent to him by Mr. Windsor of Manchester. The tumours exist around both shoulders, elbows, knees, and ankles; they are quite symmetrical in position, but are larger on the right than the left side. There is a distinct history of heredity, the father having similar outgrowths in the same situations, and exostoses being found in four generations, at least, chiefly about the knee. In the museum of the Newcastle Infirmary the President had found a skeleton with a large number of exostoses. Mr. Price of Margate had also published a similar case in THE LANCET, and ten years ago he himself had had a lad in the London Hospital under his care with exostoses growing near the large joints; he removed the largest of these, which was near the knee, and he nearly lost the patient from inflammation. He had never seen these multiple exostoses in the female sex.—Dr. PAYNE had made the autopsy on a case shown to this Society by Mr. Arnott—a woman about eighteen years of age, from whom a large exostosis near the knee-joint was removed, death resulting from inflammatory complications. Exostoses were found on every bone in the body except the skull, pelvis, and ribs. He did not know the family history.—Dr. POORE had published in THE LANCET a case of a little girl under his care at the Charing-cross Hospital, who had several exostoses. No hereditary history known.—Mr. BARKER had seen a case at University College Hospital of a girl aged seventeen, with symmetrical exostoses on the bones of the fingers, wrists, elbows, and femora. No history known.—Dr. STURGE mentioned the case of a man forty years of age with remarkably symmetrical exostoses growing from the humeri, ulnæ, radii, metacarpal bones, scapulae, and clavicles.—Mr. PEARCE GOULD had seen a few years ago twin brothers, about five years of age, each presenting exostoses on the upper and lower ends of the humerus, which were symmetrical and alike in both except that one humerus had no exostosis on its upper end. There were also rickety "spines" on the tibiæ in each leg. The case was of interest as showing some hereditary influence.—Mr. EVE remarked that the specimens of such exostoses in St. Bartholomew's Museum showed all the outgrowths springing from the epiphysal line. He showed a lower jaw-bone on which was a large exostosis springing from the inner alveolar wall on each side at the level of the bicuspid and molar teeth, exactly symmetrical.—The PRESIDENT was glad to have elicited so many examples in females. In the family of the case he specially brought forward there had been a close intermarriage—two first cousins, three generations back—which may have had some influence in the production of the condition.

The PRESIDENT also showed a Tumour which he had

removed the day before from the leg of a woman forty-six years of age. The growth had existed twenty years, and for ten years had been ulcerated, fungated, and in its present condition. At first sight it resembled an epithelioma, but the tumour overhung the margins of the aperture in the skin. There was no warty growth, no infiltration, no disintegration, and the surface was florid, clean, with a sweet discharge. In the groin were several enlarged glands. The tumour was found to adhere to the deep fascia, part of which was removed with it. The enlarged glands were also removed. — Mr. PARKER had made a hurried examination of the growth, and had found it to consist of lobes of epithelial tissue, which he regarded as proliferated sebaceous glands, separated by strands of fibrous tissue. The growth in the glands was of a similar nature. The case differed from ordinary sebaceous tumours in its infecting the glands, and was of interest as showing that there is no hard and fast line of separation between benign and malignant tumours. — Dr. THIN had examined Mr. Parker's sections, and thought they resembled those of the growth on the cheek shown last year by Mr. McCarthy. In a case of an ulcer over the scapula, which had existed forty-three years, he had found a very similar tissue in the thick tumour-like margin—loose connective tissue, with epithelial masses in the meshes. He pointed out that at present there was no evidence of the development of these tumours from sebaceous glands; the epithelium differed from that in these glands, and there was no sebum to be found. At the suggestion of the President, the specimens were referred to the Morbid Growths Committee.

Dr. N. MOORE related a case of Primary Cancer of Lung and Embolism of the Middle Cerebral Artery. The lung was hard and shrunk, with dense masses of cancer, continuous with a large mass around the root of the lung. The cervical and mediastinal glands were also enlarged. There was no other growth elsewhere, so that it must be considered a primary tumour of the lung. In structure it was made up of a firm fibrous stroma, with tubes and spaces lined by epithelium; it was therefore a cancer of glandular origin, and he believed it originated from the crypts of the bronchial mucous membrane. Just before death the patient was seized with aphasia and right hemiplegia, and an embolism of fibrin was found in the left middle cerebral artery; this must be considered an accident in the case. — Mr. R. PARKER referred to his paper on Primary Cylindrical Cancer of the Lung read before the Medical and Chirurgical Society, in which he had fully described one case and referred to two others. He could find no reason why cancer should not develop primarily from the lung. In the fetus the infundibula are lined by columnar cells, and it is the pressure of the air which changes the shape of the cells, which are not in nature different from those in the bronchial tubes.

Dr. N. MOORE also exhibited some Blood recently obtained from a patient who died of Diabetes in St. Bartholomew's Hospital. The man, eighteen years of age, had suffered from the disease for two or three years, and had become very emaciated; a day or two ago he was greatly distressed by some news, became suddenly worse, unconscious, and in a few hours died. There were no convulsions or direct symptoms of acetonæmia. At the autopsy Dr. Moore noticed the blood to be of a pink colour, and that the serum which separated was milky in appearance. There was no change in the oxyhemoglobin as examined by the spectroscope, the red corpuscles were normal, the white cells rather abundant, but the serum contained a very large amount of fat granules, which rose to the top of some blood in a test tube. Dr. Gamgee had mentioned the pink colour of the blood in connexion with acetonæmia. Dr. Klein had recently lost fifty guinea-pigs quite suddenly, and he noticed both the pink colour and milky serum of the blood, but there was no reason to think the animals had diabetes. It was probable therefore that this peculiar change in the blood was met with apart from acetonæmia. — Dr. CAVAFY asked if the urine had been examined with perchloride of iron. — Dr. N. MOORE replied that it had not. — Dr. F. TAYLOR asked if any fat embolisms had been found, and whether there was any well defined condition to which the term acetonæmia could be fairly given. He had seen many deaths from diabetes, and most of them were from collapse and coma. He had seen two cases of so-called acetonæmia, but there was no convulsion. — Mr. M. BAKER asked what was the condition of the alimentary canal, and whether the condition of the blood could be explained by the sudden ingestion of a large quantity of fat. — Dr. MOORE replied that the patient had been

fed on the usual diabetic diet; that the stomach was empty and the intestines filled with dry yellow, fecal matter. He agreed with Dr. Taylor that it was difficult to define the condition of acetonæmia, but what he meant by it was a nervous condition with a strong odour of acetone before death. He should place his case in the category of those dying from collapse and coma. He had not made a special search for fat embolisms.

Mr. R. J. GODLEE showed a Tumour which he had removed from the knee-joint of a woman, aged thirty-eight. She had suffered from synovitis of the joint for four years. The tumour was felt on the outer and upper side of the patella, freely movable laterally but not vertically. He had excised it by cutting into the joint, hooking up the mass and cutting through the pedicle. The patient did well. In structure the growth was simple fibro-cellular tissue.

Mr. GODLEE also showed several microscopical specimens of Epithelioma, especially illustrating the recurrence of the squamous form in the lung, which is usually considered a rare condition. In the first case from which the specimens were taken the man had an epithelioma of the tongue and mouth, with many enlarged glands in the neck, and a large mass over the upper part of the sternum, which was inflamed and crackling. An incision into it let out turbid serum. At the autopsy several small epitheliomatous tumours were found scattered over the left side of the chest and abdomen, but not reaching across the middle line. The mass over the chest communicated with a large growth in the mediastinum by a large hole through the manubrium. In both lungs many small tumours were found, and similar ones in the liver, kidney, supra-renal capsules, and under the peritoneal surface of the diaphragm. Examination of these tumours showed them to be very much like one he had recorded in the Path. Soc. Trans., vol. xxvi., where there was also a recurrence in the lung and pleura. In the tongue and most of the smaller growths there was a very irregular collection of epithelial cells, with very little stroma and imperfect "nests"; in most cases there was an absence of the common serration of the cells. In the kidney the growth was very typical. He thought these specimens illustrated the principle that the further a tumour deviates from the normal tissues, the more malignant it was; the irregular arrangement of the connective tissue and the epithelial spaces marked out this growth as very heterologous, and it showed a more marked malignity than most epitheliomata in which recurrences in internal organs were rare. The other case was an epithelioma of the bladder, met with in a man seventy-eight years old, who suffered from dribbling of urine and difficulty in micturition; he was greatly emaciated and pale. At the post-mortem examination a large tumour was found growing from the posterior and upper part of the bladder, in the centre of which was a large ragged cavity leading through into the peritoneum; there was chronic cystitis and acute peritonitis. The only secondary deposit was a small patch in the back of the left lung, grey in colour, mottled with white specks. The primary tumour was an irregular epithelioma; in the lung the arrangement was more regular, and in places the growth was almost like true skin, with papillæ and horny epidermis. — The PRESIDENT referred to a case of cancer of the tongue, which had recurred locally several times, and had been removed on each occasion. There was a recurrent growth in the lungs just like that in Mr. Godlee's case.

Mr. PEARCE GOULD showed a microscopical section of a Mucous Polypus of the Umbilicus. The Polypus was met with in a boy five months old, in whom it was noticed when the cord fell off. It was soft, florid, pedunculated, about the size of a large pea, with a small central aperture. The pedicle was ligatured, and the growth removed, and prepared for examination by Dr. Gibbes. It was a true mucous polypus, composed of branching tubes lined by a single layer of cylindrical epithelium, with a finely fibrous and nucleated stroma. From its close resemblance in structure to the mucous polypi of the rectum, Mr. Gould suggested that it was developed from the remains of the umbilical vesicle.

Dr. PAYNE showed a living specimen—Joint Disease in Locomotor Ataxy. A man, aged thirty-four, had syphilis ten years ago. In June, 1879, he suddenly felt great weakness in his legs, in which he had had sudden sharp pains for two years previously. There was then well marked ataxia, which much improved under anti-syphilitic treatment. Five months ago he returned to the hospital complaining of his left knee, in which there was considerable synovitis, but

no evidence of any definite change in the bones; in the right knee there was a little thickening of the upper end of the tibia. Gastric disturbance had been quite absent until a week ago, when he was seized with vomiting of clear fluid. There was also a small ulcer in the sole of the foot. Dr. Payne considered this as probably a very early condition of the peculiar joint change met with in locomotor ataxia. Mr. Nettleship had examined the man's eyes, and found that there was no disease of the optic nerve, the pupils were motionless to light and nearly so to accommodation.—Dr. BUZZARD had questioned the man, and found that he owned to attacks of retching at times during the last three or four years. Out of nine other cases of ataxic arthropathy as many as six had distinct gastric crises.—Mr. BARROW asked whether this were not syphilitic disease of the knee.—Dr. PAYNE thought that time only could answer that question; but the joint had become affected while the man's general condition was being improved by anti-syphilitic treatment.

Dr. PAYNE also showed a man, forty-two years of age, who when eight years old had measles, and afterwards, under the left side of the lower jaw, there developed a swelling larger than an egg, which gradually subsided. From that time the left side of the head and face ceased to grow. In 1848 he was seen by Romberg, and was one of the cases on which he founded his views on trophic nerves. All the left side of the head and face, with the doubtful exception of the back of the head, is markedly smaller than the right; there is no impairment of sensation, nor paralysis of muscles. The affected part corresponds with the distribution of the fifth cervical nerve. Hearing is less acute on the left side, and he says his sight, smell, and taste are not so good as on the opposite side. There are bald patches above the left ear and in the left eyebrow. No affection of the limbs; tongue very much smaller on the left side, and protruded much to the left; but it is doubtful whether this is due to paralysis or to the altered shape of the parts. Facial nerve not affected. No difference in vascular supply or sweating on the two sides; and in this it differs from cases of injury to the sympathetic nerve. Dr. Payne considered the atrophy to be due to some affection of the fifth nerve.—The PRESIDENT remarked that this was the most extreme example of this hemiatrophy that he had ever met with. In his opinion such a condition followed on morphea, and he had himself published cases to illustrate this. In Eulenberg's essay on the vaso-motor nerves it is suggested that morphea is due to an irritation of these nerves keeping up a constant contraction of the vessels, and so leading to subsequent atrophy. His own explanation, however, of this case was that it was due to some disease of the vaso-motor nerves travelling in this case along the branches of the fifth nerve, as there is no loss of sensation, nor are the muscles supplied by the fifth nerve implicated. The President exhibited a middle-aged woman with very large and symmetrical patches of morphea on the lower extremities and abdomen; it had existed six years. The patches in the thighs were markedly symmetrical, and not corresponding with the distribution of any nerve; but on the abdomen there was a long oval patch sloping down just in the same way as herpes zoster does, with which this disease has great analogies. He had never before seen the disease symmetrical. It was limited to the lower extremities as much as paraplegia, and at other times attacks upper limbs only. Sensation was unaffected, pain was unusually severe.—Dr. POORE regarded Dr. Payne's case as arrested development, not atrophy, the left side of the face was that of a child. The skin of the left side was quite unaltered in texture, and had no resemblance to morphea now, and the vessels on that side were larger than on the right. He thought that the cause of the affection had quite passed away, and that it was a mistake to speak of any affection of the nerves as now existing. He suggested that the connexion between the fifth and vaso-motor nerves had been interfered with, and sensory impressions failed to be conveyed to the vaso-motor nerves governing the vessels. The large size of the vessels looked as if one of their incitements to contraction had been lost.—Dr. BUZZARD compared it to infantile paralysis of the lower limbs, and suggested that the cause was to be found in a myelitis of the medulla oblongata.—Dr. PAYNE adopted Dr. Buzzard's view, and suggested that the seat of the lesion was probably in the Gasserian ganglion. It was not simply an arrest of development, the wrinkles on the left side marked the cheek as twenty years older than the right.

Dr. LEES showed a child who had recovered from severe

inflammation of the distal ends of the diaphyses of the left humerus, left femur, left radius, and upper end of right humerus; there was suppuration at two of these seats of disease. The child was syphilitic, and was treated by mercury, and had made a very excellent recovery. It had been called epiphysitis; as the seat of the disease was the end of the diaphysis, telostitis was a better name. The multiplicity and severity of the affection, the early age of the patient—six weeks at the onset of the malady—and the good recovery, made the case one of unusual interest.

Card specimen by Mr. Shattock: Dissection of Cleft Palate in Adult.

MEDICAL SOCIETY OF LONDON.

Pleurisy with Effusion.—Aneurism of Ascending Aorta.—Atrophy of the Stomach.

AT the meeting of this Society on the 1st inst., Mr. F. J. Gant, President, in the chair—

Dr. DE HAVILLAND HALL read notes of a case of Pleuritic Effusion. The patient was a discharged soldier, aged thirty-two, admitted into Westminster Hospital on July 23rd, 1880. His illness dated from April 1st, when he had the usual symptoms of an attack of acute pleurisy. He was confined to bed for eight weeks, at the end of which time, though a good deal better, he still complained of considerable dyspnoea. On July 19th he caught a fresh cold and had a relapse. On admission, the patient, who was suffering from incomplete aphonia, presented all the symptoms and physical signs of extensive left pleural effusion, dullness extending all over the front of chest, except quite at apex, and passing across to the right side of sternum. Posteriorly there was a boxy note in the supra-spinous fossa, and absolute dullness from angle of scapula downwards. At first it was not possible to detect the position of the apex beat, but on July 27th it was found impinging half an inch to inner side and below the right nipple. After a fortnight's treatment with diuretics and iodine he was tapped, and forty-two ounces of straw-coloured fluid were drawn off and all treatment by drugs suspended. The aspiration was followed by improved breathing over the affected lung. On September 3rd, as the condition of the patient remained stationary, he was again aspirated, and 110 oz. of clear, straw-coloured fluid withdrawn. While the last pint of fluid was flowing he complained of intense pain in the left chest, especially posteriorly; the pulse became so feeble and the general aspect of the patient so alarming, that the aspirator had to be withdrawn, though the fluid was flowing freely. The pain lasted some hours, but was relieved by the subcutaneous injection of morphia. On Sept. 7th there was harsh breathing all over left front. On Sept. 30th aspiration was again resorted to, and fifty-five ounces of similar fluid drawn off; extreme pain again led to the withdrawal of the aspirator, whilst the fluid was still flowing. He was discharged much relieved on Oct. 12th, in order to go to the seaside, and to be readmitted if necessary on his return. After alluding to the large amount of fluid drawn off, Dr. Hall said that the point on which he wished to get the opinion of the Society was as to the quantity of fluid it is desirable to evacuate at a single sitting. He quoted the views of Walshe, Anstie, and Fraenkel on the subject, and did not agree with the latter in laying down a hard and fast rule that not more than a definite amount should be removed at once, but was disposed to coincide with Anstie that the withdrawal of fluid must be arrested when the patient begins to complain of constricting pains in the chest or epigastrium. After both aspirations the fluid remained quite clear. On the evening of the first tapping the temperature rose to 101°, and then rapidly fell; on the second occasion it only rose to 99° 8', and on the third occasion the rise to 99° 6' took place on the evening of the day following the aspiration. The incomplete aphonia which was present on admission was merely of catarrhal origin, and in no way connected with the effusion, as in a case recently recorded in THE LANCET by Dr. Poore.—Dr. THOROWGOOD was not quite satisfied with the use of the aspirator, seeing that the operation had to be repeated

so often. It was his habit to suspend the operation as soon as pain was complained of or the patient showed distress. He referred to a case under his care in which pus in the first instance was drawn off. A second aspiration a month later brought away blood mixed with serum. He thought this due to an exudation of blood corpuscles through the thin walls of new bloodvessels. The operation was persevered with and the patient recovered. He asked whether any Fellow had seen recovery follow a single operation with the aspirator.—Dr. SYMES THOMPSON mentioned a similar case to that of the author in which he had followed the suggestion of Mr. Parker, and introduced air into the chest in place of fluid. In many cases it was better to remove the fluid by a syphon rather than with an aspirator.—Dr. GILBART SMITH referred to a method introduced by his colleague, Dr. Hensley, at the City-road Chest Hospital, by which cases, especially of purulent effusion, were treated. Two trocars were used, and by an ingenious arrangement of stop-cocks the effusion could be withdrawn from an opening simultaneously with the introduction of carbolised water, plain water, or iodised water through the other; or the direction of the current could be reversed, in case of a blocking of the tubes.—Dr. SANSOM mentioned a case where a single aspiration had been sufficient.—Mr. PEARCE GOULD considered tapping was often too long delayed; it should be resorted to before the lung had become bound down by tough adhesions. He did not see the benefit of the introduction of carbolised water or air, and thought that the more slowly the fluid was abstracted the better.—Dr. WARNER referred to a case under his care six weeks ago at the London Hospital. On admission a large quantity of serous fluid was withdrawn by the aspirator. A month later thirty-eight ounces of pus were removed; rapid accumulation followed, which necessitated a third operation in ten days more. This not giving relief, Mr. Couper's advice was sought, and he inserted a second tube at the angle of the scapula, when a large quantity of pus gushed out, and continued to flow with expiratory movement for some time. This has resulted in the improved physical signs and condition of the patient. He also gave instances of a too rapid withdrawal of pleuritic effusion.—The PRESIDENT pointed out the decided advantage of counter openings for the prevention of the accumulation of fluid.—Dr. HALL, in reply, stated that in one case in which he had withdrawn seventy-seven ounces, no return of the fluid had occurred. It was not advisable to tap during the feverish stage unless dyspnoea were urgent. His plan was to insert a drainage-tube should the second tapping be followed by return of the effusion.

Dr. SYMES THOMPSON brought forward a specimen of Aneurism, involving the whole ascending aorta—from the pericardium to the aortic arch. The vessel was studded with patches of atheroma, and several calcareous spiculae projected from its inner surface. The dilatation above the sinuses of Valsalva was as large as a Tangerine orange, and a sacculus pressed upon the apex of the left lung. The right lung was covered by tough and thickened pleura; in the upper lobe were two small cavities, with semi-fluid caseous contents, and a larger cavity full of foul grumous fluid occurred in the lower lobe, where also were numerous dilated bronchi. The left lung, although congested at the apex, was otherwise free from disease. The symptoms during life were not characteristic of aneurism. When admitted into the Brompton Hospital in June the patient complained of cough, expectoration, and dyspnoea on exertion, and there was some oedema of legs and abdomen. There was dulness and bronchial breathing under the left clavicle, and dulness with crepitation and rhonchus at the right base. The area of cardiac dulness was increased leftwards and the apex beat was half an inch outside the left nipple. There was no murmur. The cough increased, the dropsy extended to the upper extremities, and the patient died on September 12th. He had suffered from pleurisy twelve years before, but never from rheumatism or syphilis. He was forty-four years old, but had been in failing health for ten years. Dr. Symes Thompson remarked that when an aneurism compresses a bronchus and leads to secondary changes in the lung the primary disease is apt to be masked, and the tumour being deep-seated, the diagnosis between chronic pleuro-pneumonia and aneurism becomes difficult. The urgency of the dyspnoea, the pain and palpitation, awakened grave suspicion in this case, which was strengthened by the persistent and anomalous disturbance within the chest.—The base of the lung had the appearance on section of multiple abscesses dispersed through it. These

"abscesses" are really distended bronchial tubes full of retained secretion, the peribronchial tissue being thickened by inflammation. It seems probable that pressure upon the nerves at the root of the lung, by lowering the vitality of the organ, rendered it liable to inflammatory changes, just as complete destruction of these nerves leads to pulmonary gangrene. The pressure on the nerves may also have caused—as suggested by Dr. Risdon Bennett—paralysis of the bronchial muscles, leading to retention and accumulation of secretion. It was not clear in the present case that the bronchus was much compressed by the aneurism, but the nerve-plexus must have been seriously involved.—Dr. EWART described the post-mortem appearances found in this case; alluded to the difficulties of diagnosing the presence of aneurism, and referred to the fact that the superior cava generally suffers pressure.—Dr. GILBART SMITH referred to the important series of cases showing the effects of pressure upon the bronchi brought before the Pathological Society by the late Dr. Pearson Irvine. The present case was unusual in the right and not the left bronchus being the seat of pressure. While admitting that nerve-pressure might have some share in enfeebling the lung, as shown long ago by Sir W. Gull and Dr. Habershon, he considered that both lungs should be affected by such pressure on the pulmonary plexus. Probably the pulmonary condition was due to narrowing of the bronchus, leading to an enlarged and emphysematous condition from interference with expiratory rather than inspiratory efforts. In proportion as the calibre of the vessel became restricted, inflammatory and disintegrating changes would be set up by the retention of secretion. The fetid character of the secretion in Dr. Thompson's case showed that ingress of air was not wholly prevented.—Dr. SYMES THOMPSON, in reply, said that the pupils and pulse were equal, and there was no alteration of voice or laryngeal cough.

Dr. THOROWGOOD read notes of a case of Atrophy of the Stomach. The patient was a woman, aged twenty-three years, admitted into the West London Hospital on Sept. 6th on account of constant vomiting of all food. There was no sign of any thoracic or cerebral disease. The region of the stomach was very tender on pressure, but no tumour could be felt in any part of the abdomen. There was no diarrhoea and no vomiting of blood. A variety of medicines, reputed valuable for the arrest of vomiting, were vainly tried; but it was only after a hypodermic injection of morphia that any tolerance of the mildest nourishment could be obtained. Life was maintained chiefly by nutrient enemata of beef-tea. The patient died on Oct. 5th, having on the day previously vomited blood for the first time. There was no very marked emaciation. All the organs were sound with the exception of the stomach, which was remarkably thin and wasted. When cut open some grumous fluid escaped, and the lining membrane was smooth, free from rugæ, and of a yellowish hue. At the cardiac end some arborescent congested vessels were seen. A portion was given to Dr. Fenwick for examination, and he found well-marked intertubular gastritis with granular and fatty degeneration of the tubules. Dr. Fenwick was disposed to look upon a subacute gastritis as the essential cause of the wasting of the stomach.—Dr. SANSOM called attention to the administration of enemata of defibrinated ox-blood in quantities of four to six ounces twice or thrice a day, as recommended by the Therapeutical Society of New York. He had carried this out successfully in a case of idiopathic progressive anæmia when the stomach rejected everything. After a time the stomach became tolerant, and arsenic was administered. Dr. Sansom thought the method offered a good prospect of successful treatment in numerous cases in which the stomach was wholly or in a considerable degree intolerant of food.—Dr. TIMMS thought that in this case no treatment would have been successful; but less advanced cases had derived much benefit from the use of hydrochloric and other mineral acids.—Dr. DOUGLAS POWELL referred to a case under his care at the Middlesex Hospital, where the diagnosis was extremely difficult; obstinate vomiting and extreme emaciation were present, without any evidence of cancerous disease, gastric ulcer, or uterine disorder. Great improvement had followed treatment by nutritive enemata and peptonised food. He thought Dr. Sansom's suggestion of much value.—Dr. DOWSE pointed out that Dr. Thorowgood's case was of inflammatory origin, and not due to a lesion of the semi-lunar ganglia, in which case atrophy would occur apart from inflammation.—Dr. THOROWGOOD replied, and the meeting adjourned.

Reviews and Notices of Books.

The Royal London Ophthalmic Hospital Reports. Edited by JOHN TWEEDY, F.R.C.S. Part I., Vol. X. August, 1880. London: Churchill.

THE new volume of the Ophthalmic Hospital Reports opens well, and Mr. Tweedy is to be congratulated on having collected a valuable series of original articles. Mr. Lawson discusses the treatment of sympathetic ophthalmia. He considers that whilst sympathetic irritation may be arrested by removal of the injured eye, this proceeding will not stay the progress of sympathetic ophthalmia, and he therefore holds that if the injured eye retain any sight it should not be removed when sympathetic ophthalmia is established, a point in which we are disposed to agree with him, having seen several cases where the injured eye, after sympathetic ophthalmia had destroyed the opposite eye, retained sufficient vision to be very useful. We coincide with him also in deprecating any operative interference, such as iridectomy or sclerotomy, in the eye secondarily affected during the earlier stages of the inflammation, though it may be improved at a later period either by an iridectomy or by the removal of the lens. Great caution, however, should be exercised in meddling with such an eye, as if inflammation be set up sight is irrevocably lost. Mr. Lawson finds sclerotomy useful where pain is experienced. He places several cases on record.

The second paper, which is a very valuable one, is by Dr. Brailey on a Theory of Glaucoma. After alluding to the theories of Donders and Weber, both of which Dr. Brailey believes have an element of truth in them, he thinks there is both an increased inflow of blood into the eye, and obstruction to the exit of the lymph and fluids secreted. The enlargement of the vessels is probably the consequence of an affection of the vaso-motor nerves, and the connexion between neuralgia and mental anxiety, which is no doubt of very common occurrence, may thus be accounted for. The obstructed escape of the aqueous humour is due to the application and adhesion of the periphery of the iris to the cornea. He gives a classification of cases of glaucoma. Upon the whole Dr. Brailey's views seem to us to be the nearest to the truth, and the best substantiated that have hitherto been advanced.

A very different theory has been suggested to account for glaucoma by Dr. Priestley Smith, in the next following article to that of Dr. Brailey. Starting with the observation that the intra-ocular fluid escapes from the interior of the eye at the angle of the anterior chamber, and that this angle is closed in glaucomatous eyes, he endeavours to show that the closure is due to two factors, an increase in the size of the lens, and a swelling of the ciliary processes. This proposition he endeavours to maintain by a considerable number of photographic drawings.

The next paper is by Mr. George Berry on Central Amblyopia. This affection seems in the great majority of cases to be a toxic affection most commonly caused by the abuse of tobacco; the vision is noticed to become rather rapidly impaired, so that the patient finds he is unable to read, and his general health is sometimes impaired. In the defectively sensitive part there is more or less red-green blindness. The prognosis is good, since recovery usually takes place if the patient has strength of mind sufficient to enable him to give up smoking.

Mr. Couper gives a drawing and description of a new ophthalmoscope, which seems to be convenient and useful.

Dr. Litton Forbes furnishes a paper on Keratotomy, in which he shows that the refraction of the eye may be determined by simple examination of the lights and shadows thrown by a concave or plane mirror on the cornea. The

plan seems to have answered well in his hands, but would probably require much practice and very close observation.

Mr. Morton gives a note in which he describes some remarkable phenomena of pulsation in the vessels in cases of embolism of the carotid artery of the retina. Mr. Lawson suggests the use of variously-sized seeds as a means of determining the vision of children too young to be tested by means of types. Mr. Gunn gives some notes of the mode of treatment adopted at Moorfields for ordinary cases of gonorrhoeal ophthalmia, iritis, cataract, &c. Finally, Dr. Brailey and Mr. Edmunds give a long and carefully drawn-up report of the condition of the optic nerve and other parts of the eye in cases of increased tension. Altogether the number is a very good one.

The Dissector's Guide. By D. J. CUNNINGHAM, M.D., C.M., F.R.S.E., Senior Demonstrator of Anatomy, University of Edinburgh. Part II. The Abdomen. Edinburgh: MacLachlan and Stewart. 1880.

AMONG the numerous manuals of dissections which are used by students in our anatomical schools, we think that Dr. Cunningham's new work must take a conspicuous place. Primarily designed for the students of the Edinburgh University, and so following the methods in vogue there, it has such intrinsic merits that when known in other schools it is sure to become a favourite. The second part is much fuller than that previously issued, and in many ways a great improvement on it, and we regret that the author should have deemed it necessary to publish the work in this fragmentary fashion. We hope that the other parts will be speedily issued, and the whole work republished in a single volume, for a "guide" subdivided into parts is rarely acceptable to the student, and never meets with the appreciation which would be accorded to it if published in a more convenient form. The fulness with which the methods of dissection are described, and the omission of all details of minute anatomy, which, as the author observes, are altogether out of place in a text-book upon Practical Anatomy to be used in the dissecting room, constitute the special features of the work. The various procedures necessary for examining the structures in the male and female abdomen are most carefully pointed out, and no one can follow Dr. Cunningham's instructions without gaining a thorough knowledge of their anatomy as far as this can be seen with the unaided eye. The descriptions of the peritoneum and pelvic fascia are remarkably lucid and comprehensive. Besides the ordinary illustrations in standard anatomical works, many new diagrams and plates are introduced, and these are very clear and of great service in explaining the text. We must congratulate the publishers on having done everything in their power towards making the book acceptable to the student and the teacher.

The Ocean as a Health-Resort. By W. S. WILSON, L.R.C.P., M.R.C.S. Small 8vo, pp. 260. London: J. and A. Churchill. 1880.

WE have read every page of this book, and have derived from it both instruction and amusement. In the present day, when voyages are so often recommended on the score of health, it is very useful to have a practical adviser—at once a sailor, a man of science, and a medical practitioner—to tell both doctor and patient what to do and what not to do, what a voyage at sea is really like, what are its shortcomings, and what are the benefits likely to arise from it. All this will be found in Mr. Wilson's book, and we should advise all who are going a voyage for the first time to furnish themselves with a copy of it.

THE Court of Quarter Sessions have voted £35,000 for enlarging the Stafford Lunatic Asylum.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 6, 1880.

WHAT has happened at Guy's Hospital is happening, or may happen, at any moment in similar institutions elsewhere. The inter-relations of governors, medical officers, and nurses are almost everywhere strained and "gritty." Why is this? We think it is because the general arrangement of affairs—the organisation as it may be called—is faulty, and in all ways calculated to go wrong and give rise to a great deal of unnecessary friction, and to become destructively heated, whenever the smallest mishap occurs, or interlocking "departments" are the least bit shifted. Let us see how such things can be, and so try to find a remedy.

The governors of a hospital *are*, and must ever be, its responsible managers. This much should be distinctly laid down at the outset of every discussion of "hospital management," whether what follows is intended to affirm principles broadly, or to state and criticise a special set of circumstances which may encompass a particular institution. When we contend for the introduction of a medical element into the system of hospital management, and assert that such an element is *necessary*, we do not mean to imply that a hospital ought to be handed over to its physicians and surgeons, but that there should always be a sufficient number of medical men on the Board of Governors, and that the policy pursued should clearly recognise that the aims and ends of the charity are exclusively medical. The governors are the managers, but they are not, therefore, autocratic, and bound by no law of procedure. There is such a thing as constitutional government, and constitutional government is the only sort of rule which can be finally safe or successful in connexion with hospitals. The administrative staff of a fairly large hospital may number from thirty to forty physicians and surgeons, who practically serve the institution gratuitously, and whose work and status bring it fame. This fact should, in itself, be sufficient to convince any sensible body of men acting as governors that they cannot treat the hospital under their control empirically, or expect its staff to submit to ordinances promulgated without due consideration. Nor is this all; the staff must be made party to every detail in the system of government if the business of the institution is to be carried on harmoniously. We are now speaking of *general* business. In regard to *professional* business—that is to say, the surroundings, accommodation, feeding, and disciplined nursing, of the sick—none but the most wrong-headed and fatuous of Boards of Governors would presume to interfere. If the medical staff of a hospital were to invade the treasurer's office and direct that the accounts should be kept on some particular system, and were to claim the right of displacing the clerks, or if they were to intrude into the kitchen and insist on engaging the cook and her assistants, or into the laundry and claim to superintend the washerwomen, they would have far better and more cogent reasons to offer in explanation of their audacity than those which the lay governors of a hospital can adduce in ex-

tenuation of the insufferable folly of seeking to control the "nursing."

There is something so preposterous in the encroachments recently made by the governing bodies of hospitals on the province of medical duty, that it must be confessed the profession has been a little remiss in not making a proper stand against the movement. It may hereafter become an interesting topic of inquiry to what we owe this outburst and exercise of energy. For the moment, however, we are too much concerned with the practical question to indulge in speculations as to the metaphysical. The duty of the instant is to assert that the medical profession cannot tolerate the assumption of distinctly medical authority in the treatment of the sick, and that rather than sanction a course like that recently pursued, the better portion of the profession would withdraw from hospital charity, leaving it to the misguided trustees of public funds and property bequeathed for the benefit of the sick poor, to work out their folly. It is within the province of the governors of a hospital to administer its funds, and to select the *personnel* of its establishment, subject to the traditions and needs of the institution, the proper judges of what these traditions and needs require being skilled counsellors: for example, in all that concerns the medical interests, care and treatment of the sick, inclusive of accommodation, diet, and nursing, the medical and surgical staff are obviously the legitimate advisers. It is within the province of the governors to see that the charity is not misdirected, squandered, or abused; and it is their duty to exercise the sort of control which a constitutional government exercises over the general affairs of a state or community; always remembering that civilians do not attempt to manœuvre armies in the field, to navigate fleets, or interpret laws and administer justice. On the same principle the lay governors of a hospital must refrain from interference in matters so obviously professional as are the care and treatment of the sick. It is not difficult to trace the limits of the authority entrusted to the governors of hospitals, or to define the functions they are expected to perform. It should not be difficult, with the combined good sense of the gentlemen who devote time and trouble to hospital management, and the sagacity and judicious and dignified firmness of a staff of educated physicians and surgeons, to secure that these limits shall be duly recognised and observed.

The medical officers of a hospital are practitioners at whose disposal public philanthropy or private benevolence has placed a house of shelter and an organisation for the cure of the sick. It is the professional business of physicians and surgeons to administer remedies, to direct the general management, and to superintend the nursing of their patients. With their own hands, or by those of the pupils their personal fame or that of the institution has brought around them, they should perform all operations, dress all wounds, and generally discharge the duties which compose the detailed treatment of disease. We are speaking plainly all round, and the truth needs to be spoken to the medical staffs of hospitals not less than to their governing bodies. It is, very much, to the neglect of practical instruction in "dressing," which has notably increased of late years, that some of the worst evils now rife in the hospitals are due. In the pursuit of *higher* branches of scientific education,

pupils have been allowed to neglect the humbler, but not less useful, functions of the "dresser." Dressing, properly defined, includes much that is now left to nurses. In the old days pupils applied *all* dressings, whether of simple lint, ointment, or plaster. They, of course, and only they, applied splints; they, and only they, exercised any "discretion" as to the treatment of the sick. There were, happily, no "sisters" in those days, and no matron ever presumed to vary an order, or herself assume the function of treating the sick. The women of the establishment acted as servants; their chief as housekeeper and disciplinarian of the female attendants under her, and she was content in this purely *domestic* department, if only her fidelity and that of the women serving under her were approved. We repeat that it is in large measure because "dressing" has come to be more restricted in its offices for the comfort of the sick "nursing" has grown out of due proportion, and become mischievous to the system of which it forms only a small and wholly subordinate part. How, we ask, can pupils be properly trained and instructed for the daily business of practitioners among the sick, if they are not permitted to learn the minor and practical details of their calling in the wards of a hospital? Does the study of medicine or surgery consist, can it be achieved, in walking round the wards of a hospital, making *scientific* investigations at the bedsides of *selected* cases, and picking up a smattering of morbid anatomy elsewhere? The older physicians and surgeons could direct the application of blisters and poultices, and even order the creature comforts of the sick chamber, because they had obtained a practical knowledge of details in the wards of the hospitals. It is much to be feared that the present generation of practitioners are not so expert; and looking to the way in which clinical study is prosecuted, the cause of the altered state of things is not far to seek. If the medical officers of hospitals do not wish to be crowded out of their proper sphere, to find their functions curtailed and their authority crippled, they must reoccupy the province from which they have practically retired, and by their own hands and the aid of their pupils—to the lasting advantage of these young men—perform their full functions, and put in exercise the authority they claim. It can only be wrested from them by their own consent. In so far as the consent to encroachment has been tacitly given, it must be wisely, courteously, but firmly and unhesitatingly, withdrawn.

The "nurses" in hospitals are, and should be content to be, servants of the medical staff, and nothing more. In so far as their position and duties differ from those of servants in private houses attending on the sound of body and mind, they are the agents by which Medicine strives to work a cure, and all such agencies must, in the nature of things, be gathered up into the hands of the physician or surgeon who treats the case. Great social misconception and a multitude of personal mistakes have arisen from the exceptional enterprise of Miss NIGHTINGALE in the Crimea. She found an army without nurses, and in a beneficent mission which will go down to history as a marvel of self-sacrifice and skill, she filled the gap and supplied the pressing need. This circumstance did not, however, warrant a host of imitators, crazy to find a means of extending the area of woman's work, in organising a movement to usurp the position of independent "ministers to the sick" in the

hospitals at home. Trained nurses, like trained cooks or trained seamstresses, are useful and necessary in their place, but it is an essential part of their duty, and ought to be part of their discipline, to act under the physicians and surgeons to whose wards they are attached. "Systems of nursing" are absolutely bad and relatively mischievous. Individuality in treatment is a logical consequence of the individuality of morbid manifestations. Moreover, every physician or surgeon who takes a practical interest in his work has his own notions of nursing, and it is essential to the success of his practice that these should be carried into effect. The only difficulty that arises in acting up to this principle grows out of the introduction of "systems" and "methods" of nursing excogitated by incompetent persons, as the most expert and experienced of women—being without medical knowledge—must ever be. It is of course desirable in a large hospital to adopt one general system, but it is obvious to every unprejudiced person that the system so adopted must be one devised or approved by the medical and surgical staff. This is so plainly the fact that it seems waste of time and space to enforce it. The authority of a matron ought to be strictly limited to the control of nurses and the domestic business of the household; she has no place or function in the wards of a hospital except to see that they are duly cleansed, and the general arrangements kept in good working order. She cleans and oils the machinery, but she can have no part or interest in the way it is employed, the purposes to which it is put, or the end it is designed to answer. Obedience to orders, and the expert discharge of the personal offices required for the comfort of the sick, comprise "the whole duty" of the hospital nurse. The moment she wanders beyond the limits of this sphere of action, she is out of her depth, and her activity is to be condemned. It is not necessary to argue with nurses as to their duty, and it is needless to define it. One word covers the case completely—they must "Obey." When they are not simply obeying, they are, or ought to be, performing the function of kindly and expert attendants on the sick; but their duty as attendants is to be merged in, or subordinated to, their duty as servants of the physicians and surgeons on whose patients they are required to attend. If these general principles were clearly understood, there would be little chance of trouble arising in our hospitals, and no danger of a dead-lock.

WHATEVER may be the fate of metallo-therapy—and in the opinion of most authorities it is scarcely doubtful—there can be no question that the clinical investigations to which it has given rise have added to our knowledge of the physiology and pathology of sensation. It has indeed furnished us with more facts than we can yet interpret, but we cannot on that account doubt the truth of observations which rest on the concurrent testimony of many well-qualified observers. The facts are of a range very much wider than at first appeared at all likely to spring from the observations of M. BURQ. Almost every day fresh investigations come to hand, showing the strange and unexpected manner in which sensation may be modified in functional disorders of the nervous system. Of not least interest in this particular are some observations which have been published by M. GRASSET

of Montpellier, regarding the action of blisters in modifying perversions of sensibility.

The observations relate to a man who was suffering from left-sided hemianæsthesia alleged to be of six years' duration, and in whom right-sided anaesthesia had been previously and unexpectedly removed by a blister applied for pleurisy. The loss of sensation is supposed by M. GRASSET to have been due to an organic lesion of the brain, but its course and the circumstance of the previous attack of right-sided anaesthesia, render it difficult to accept this view of the nature of the case. The application of a blister over the deltoid was followed by the return of sensibility in the greater part of the limb. The restoration did not, however, return first in the neighbourhood of the blister, but in the hand, and it extended as far as a little above the elbow, the neighbourhood of the blister remaining insensitive. Another blister was then applied to the thigh, and was followed by a recovery of sensibility in the whole leg. The loss of sensation was thus reduced to the left half of the trunk, neck, and face.

M. A. ROBIN found some time ago that saturnine hemianæsthesia could be removed by the action of jaborandi, the diaphoresis appearing to be attended with a return of sensibility. The use of the drug was also suggested by a statement made by M. GRASSET's patient—viz., that when he was anaesthetic on the right side he only perspired on the left. Accordingly six grammes of infusion of jaborandi were given. Perspiration was equal on the two sides. Immediately afterwards no change in sensibility could be discovered; but twenty-four hours later, after severe perspiration during the night, sensibility returned in the anaesthetic parts.

The mode of action of diaphoresis in removing anaesthesia is a subject on which there is considerable room for divergence of opinion. M. ROBIN suggested that it is by modifying the vascularity of the anaesthetic parts. M. GRASSET, however, rejects that opinion, on grounds supplied by the further history of his patient, who presented the oscillation so often noticed in cases of functional disease. Six days after the recovery of sensibility just mentioned, there was a partial loss of sensibility on the left side of the face, passing away on the following day. A little later he had another return of partial anaesthesia in the left thigh, between the hip and the knee, which passed off after free purgation. A few days later he had another attack of partial insensibility in the same region, disappearing after three days' duration, with spontaneous sweating. This anaesthesia was just in that part of the thigh to which the blister had been applied. Still later anaesthesia occurred in the left arm and hand, sharply but irregularly limited, not according to nerve-distribution. A mustard-leaf was applied to the back of the forearm, and left in position for more than an hour, causing abundant redness, but no immediate influence on the sensibility. A few hours later, however, sensation gradually returned, the recovery commencing at the upper part of the limb. Another attack of anaesthesia was quickly removed by the application of the magneto-electric apparatus.

M. GRASSET sums up, in a series of conclusions, the main lessons of this instructive case. He points out that it establishes clearly that a blister possesses an "æsthesiogenic"

action at least as great as a magnet, a metal, or an induction current. It thus affords an additional proof of the modification of perception of sensation by peripheral influences. It affords also another reason for accepting the now scarcely doubtful principle, that metals and magnets in such cases have no specific action. At the same time the facts give no support to the view that any of the æsthesiogenic agents produce their effects by a simply peripheral action, whether circulatory or nervous. On the contrary, they demonstrate that the effect of a local application may cause return of sensibility to an anaesthetic limb in all parts except the region to which the blister was applied. Moreover, its action brings into view some of the central relations of sensation, and, taken with other facts, seems to show that there are certain regions the representation of which in the sensory centres or region of the brain (posterior fibres of the internal capsule, M. GRASSET thinks) is more or less distinct; these are the upper limb, the lower limb, the anterior aspect of the trunk, the posterior aspect of the trunk, and the face. Some of these may be subdivided, but the central subdivisions represent articular segments rather than the distribution of any special nerves. Each of these regions has a certain solidarity, and suffers or recovers as a whole.

The Times, in a recent leader, expressed the opinion that the occurrence of a death in an English convent without a proper certificate and registration would furnish an occasion for legislative interference. Mr. SHIRLEY F. MURPHY, the medical officer of health for St. Pancras, was allowed on the following morning to point out that during last year no less than 24,723 deaths in England and Wales were registered, and the bodies buried, without the production of any medical certificate, and without any inquiry before a coroner. It is true that registrars are instructed to report all cases attended with any suspicious circumstances to the coroner previously to registration. It cannot, however, be anything but unsatisfactory, from every point of view, that the responsibility of defining what constitutes suspicious circumstances should rest with the registrar; and it is certain that very few coroners consider the neglect of parents to provide medical attendance for their sick child to justify the holding of an inquest. Under a new *régime* it should be distinctly provided that one of the main objects of holding an inquest is to ascertain the cause of death, when no other satisfactory evidence is forthcoming. How far this is the case at present we learn from an official return just issued by the Home Office. It appears that 27,056 inquests were held in England and Wales during last year, at an average cost of £3 each. From the verdicts, it would seem that in no less than 9776, or more than a third of the total number, the cause of death was not determined; indeed, in so many as 3046 cases the unsatisfactory verdict of "Found dead" was returned. The Births and Deaths Registration Act enacts that the "cause of death" is one of the several particulars concerning a death which is the subject of an inquest to be certified by the coroner, for entry in the Death Register. This enactment is ignored, however, by a large number of coroners, hence the perpetuation of the old-fashioned and comparatively meaningless verdicts, "Visitation of God," "Found dead," "Accidentally

killed," &c. In a large proportion of cases of sudden death from natural causes, the medical attendants of the deceased would be prepared to give satisfactory evidence of the true cause of death, but their evidence is not called for. At the present time, when the laws affecting coroners are under consideration for the purpose of revision, it is well not to lose sight of the necessity for instituting some system of certification in cases where no medical certificate is forthcoming, and where no inquest is held. A memorial has recently been presented to the Home Secretary, under the advice of the medical officers of health in Wandsworth Union, praying for legislation, with a view to check the present dangerous facility for the registration of uncertified causes of death. It is proposed in this memorial that the duty of inquiry and certification of causes of death, not otherwise certified, should be imposed upon medical officers of health. The subject is too important to be lost sight of, but it is so intimately connected with the present defects of the law relating to coroners, and the suggested remedy is so bound up with the present unsatisfactory *status* of medical officers of health, that we can scarcely hope for a prompt alteration of the present condition of things with regard to registration of deaths.

Annotations.

"No quid nimis."

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE above newly-formed society held a very successful opening meeting on the 28th ult., under the presidency of Mr. Bowman. The laws of the society were read and approved, and the number of members of council was increased to admit some well-known provincial ophthalmologists into that body. After these preliminaries the society at once entered upon its special work. Dr. Gowers exhibited and described two very interesting cases of optic neuritis; Mr. Nettleship exhibited a case of tumour of the iris. A feature in the proceedings, which might with advantage be followed in some other societies, was the discussion of cases exhibited before the reading of papers was commenced. The paper of the evening was by Mr. J. Hutchinson, detailing a case of retinal hemorrhages in a young man, and discussing their association with the gouty diathesis, with constipation and increased arterial tension. Several members took part in the discussion, of which we hope next week to give a brief report. Already a very considerable list of original members has been obtained, including many physicians and surgeons, in addition to pure ophthalmologists, and the proceedings of the first meeting showed that the society did not intend to limit its operations to ophthalmic surgery only, but that the wider bearings of disorders of the eye in connexion with disease are included in its work. At the commencement of the proceedings a resolution was passed authorising the council to put themselves in communication with the Board of Trade in reference to the question of colour-blindness in persons engaged in signalling, a subject which, the President pointed out, had already engaged the attention of foreign Governments, and the importance of which can hardly be overrated.

LIBEL CASE IN INDIA.

WE have received from India a full report of the proceedings in the case of Surgeon G. C. Hall, Indian Medical Service, *versus* Surgeon-Major K. McLeod, editor, and Mr.

F. F. Wyman, publisher of the *Indian Medical Gazette*, for defamation in imputing to him unprofessional conduct. It appears that Dr. Hall, while holding the appointment of superintendent of the central prison at Allahabad, established an Eye Hospital in that city, and carried it on at his own expense. This institution met with so much success that after some time a larger house and more complete equipment became necessary for its efficient working. In view of the increased expense Dr. Hall made an application to the Government, through the head of his department, to take it over and to maintain it. He was informed that before doing so the Government would require evidence to show that the hospital was likely to prove self-supporting, and he was requested with this object to forward to them his subscription list. As he had hitherto supported the hospital chiefly at his own expense, no such document existed. In order to obtain the information required, he inserted in the *Indian Herald* an advertisement stating that subscriptions were urgently needed for the hospital, the number of cases which had been treated in it, with the number of operations and their results, the average cost of the institution, and the means at its disposal. Upon this advertisement the *Indian Medical Gazette*, in an editorial article, commented as follows: "Our attention has been drawn to the fact that a medical officer serving in a large town in the north-western provinces is in the habit of soliciting by advertisement subscriptions to an Eye Hospital which he has established. The medical transactions of the institution are set forth in the advertisement: 'There have been 180 major operations, including 95 cataract operations and 31 iridectomies; with one exception these have all been successful.' The advertiser is certainly entitled to be congratulated on this marvellous success, but it is hardly consistent with the feelings and usages of the medical profession. We are not surprised to find that the line he has elected to adopt has not met with the approval of his brother officers serving in the same province, and we have no hesitation in pronouncing his proceedings in this matter unprofessional." For this article Dr. Hall brought his action for defamation against the editor and the publisher. The magistrate, in his judgment, says very justly that "the sting of the article complained of, the essence of the libel charged, is of course contained in the ironically conveyed insinuation that the successes advertised were not really obtained, and in the stigma of unprofessional conduct fixed upon the advertiser. There can be no doubt in the mind of any reader of ordinary intelligence that the words 'the advertiser is certainly to be congratulated on this marvellous success' do convey, and were meant to convey, the ironical insinuation I have referred to." In addition to his own evidence, Dr. Hall called only one witness; but as the Court desired to have the evidence of a medical officer of standing on the professional points involved, the senior medical officer in Allahabad attended at the request of the magistrate for that purpose. Six witnesses were examined, by commission, for the defence, which was based on the grounds that the advertisement was rightly styled unprofessional, and was of a nature which has always been condemned by the leading professional journals in England and by the profession at large; that the statistics were rightly styled "marvellous," as being quite unprecedented; that the advertisement led readers to presume that Dr. Hall was the performer of these operations; and that the accused in publishing the article acted in good faith. In a long and carefully drawn up judgment the magistrate, Mr. Markham, reviewed the whole of the evidence, and came to the conclusion that there was nothing unprofessional in the advertisement, and that no one but Dr. Hall could have signed it. "If," he says, "an unpretending, unegotistical advertisement like that in question, soliciting subscriptions for a charity and showing that that charity is deserving, is unprofessional, and

is so chiefly because it is signed by the medical man most intimately connected with the charity, then the sooner the canons of what is called medical etiquette are reformed in this respect the better." And again he observes:—"It does not do or state any of the things which its detractors say are unprofessional. Its object is one which all the witnesses say it is strictly proper for a medical man to do—viz., the collection of subscriptions for a charity, and giving the details of operations performed in a hospital is stated by all to be usual. It is true, as a matter of fact, that the operations were his own, but Dr. Hall hides these facts from the general public to whom his advertisement was addressed." Mr. Markham held that the statement that the results were "marvellous" was not true, and that the insinuation that they were falsely stated was unfounded; "the criticism conveys not an opinion properly so-called, but a slur on the private character of Dr. Hall, in that it insinuates he has been capable of publishing false statistics of his skill in order to 'herald forth' his success." On the question of good faith he also decided against the defendants, because good faith is defined by the Indian penal code to be "the doing or believing a thing *with due care and attention*," and he was of opinion that the evidence failed to show that due care and attention had been exercised by the defendants in ascertaining the facts of the case before publishing the libel. The Court thereupon found against the defendants on all the pleas, and sentenced Surgeon-Major McLeod to a fine of 300 rupees, or, in default, simple imprisonment for one month, and Mr. Wyman to a fine of 150 rupees or fourteen days' imprisonment, the expenses of the prosecutor to be paid out of the fines.

We have gone very carefully through the whole of the evidence submitted to the Court, and the judgment of the magistrate, with the result that we concur with him generally in the conclusions at which he arrived. We regret much that an officer of Dr. McLeod's standing should, with the best possible intentions, but from want of due consideration, have placed himself in so unpleasant a position, but, on the other hand, it is a satisfaction to find Dr. Hall completely and honourably acquitted of any unprofessional conduct. But although Dr. Hall has cleared himself from the serious imputation cast upon him, we are sorry that we cannot congratulate him on the course he thought it advisable to adopt for that purpose. Before commencing legal proceedings against a member of his own profession and an officer of his own service, it would, in our opinion, have been only courteous and proper to have given Dr. McLeod an opportunity of withdrawing the imputation, which we are disposed to think he would have done had those explanations been given which were elicited in the course of the trial. It was not in good taste to commence proceedings for libel without first endeavouring to settle the matter in a friendly manner. We also think it would have been much better, and equally effectual for the purpose intended, had Dr. Hall contented himself with stating the number of operations without giving the results, more especially as it appears from his evidence that they were all specially selected cases—a circumstance which must have materially affected the question of success.

UNQUALIFIED ASSISTANTS AND MEDICAL CERTIFICATES.

WE are repeatedly asked whether it is lawful for a medical practitioner to sign a certificate of the cause of death of a patient who has been solely attended by his unqualified assistant. The unsatisfactory state of registration law which permits, and indeed enjoins, the registration of every death whether or no any satisfactory evidence of its cause is forthcoming, is just now beginning to attract the attention which it has long demanded. Our correspondents' inquiry

has a somewhat important bearing upon this subject of un-certified causes of death, a considerable proportion of which is due to the practice of unqualified assistants. The form of medical certificate provided by the Registrar-General, if fully filled in, affirms that the registered practitioner signing the certificate had "attended" the deceased person, and also the date when the patient was last seen. Section 40 of the Births and Deaths Registration Act of 1874 enacts that any person who wilfully makes any false certificate or declaration under or for the purpose of this Act, and gives or sends such false certificate as true to any person, shall for each offence be liable on summary conviction to a penalty not exceeding £10, and on conviction on indictment to fine or to imprisonment with or without hard labour for a term not exceeding seven years. There can be no question that any practitioner who signs and issues a certificate declaring that he has "attended" a deceased person whom he had not seen during his or her illness makes such a false certificate as was contemplated by the above-mentioned section of the Registration Act. Under the present state of the law no one can give a legal medical certificate of the cause of a death unless the deceased person have been attended during his or her last illness by a registered medical practitioner. It is difficult to say whether the profession or the public suffers most from the abuse of the system of employing unqualified assistants.

THE RATIONALE OF COLD-CATCHING.

THE maintenance of a healthy body may be stated as an equation of force, and, by the doctrine of the correlation of forces, an equation of heat. We are compelled in dealing with the indefinable property of life—i. e., vitality—to seize upon the idea and grapple with its formula, as our want of, knowledge of the truth will best enable us. It is not the whole truth to say that the equation of internal and external heat is the problem of health preservation, because heat is only one form of motion, and, as regards the phenomena of life, electricity, magnetism, and psychic and nerve-forces, whatever these may be, are factors in the production of the result; but heat is at once the readiest expression, and, so far as we know, plays the most prominent part in the maintenance, of the health. Therefore it is not only permissible, but scientifically accurate, to lay great stress on this factor—namely, temperature—in dealing with the problem of avoiding cold and preserving a normal state of vitality. There are, accordingly, three propositions which it seems well to press on public attention at a season when great and sudden changes of external temperature beset us, and the perils consequent on such changes are especially rife. The chief, and in one sense the only, source of animal heat, is within us. We wear clothes to prevent the radiation of heat generated within our bodies to the objects around. In a state of nature, even in the tropics, it suffices to dispense with clothing in order to be normally temperate; but the use of sunshades and puggeries may serve as an illustration of the use of clothing or apparatus to prevent the access of heat from without. Practically the human organism must be maintained at a temperature equal to 96°5' of Fahrenheit in all climates. The differences of the normal temperature are very small. What is then required is as follows:—The body must generate enough heat, by the conversion of food into heat, or work into heat, to raise the body to the normal standard, *plus* whatever may be lost to surrounding objects. The use of non-conducting clothes may minimise the loss, perhaps prevent it altogether, but this will not secure a healthy temperature unless the organism generates heat sufficient for the supply which the conditions of life demand. If therefore the demand is exceptionally great at any time, the strain on the internal sources of heat will be increased in a corresponding degree, and upon the satisfaction of the demand so created will depend the pre-

servation of health. As we have said, this is not the whole truth, but it will suffice for the purpose of a practical suggestion to limit what we have to say to this aspect of the question. By habituating the organism to work at a low pressure, so to say, it is unfitted to cope with special circumstances creating an extraordinary demand. If a man has the rooms and passages of his house heated to what is called a "comfortable temperature," he practically habituates himself to produce little heat; and it may happen that even the stimulus of exercise will not evolve so much extra heat, or the recourse to additional clothing will not so minimise the loss of heat, as to render the low supply generated within his organism adequate to the need of emergencies. If this failure happens he is "delicate" or "susceptible to cold," and his health is always in jeopardy. Sometimes, by the use of a diffusible stimulant, such as alcohol in some form, or tea or coffee, he may so excite the heat-producing faculties of the organism, before going out into the cold, as to ward off a "chill"; but the effect of these artifices is very transitory, and they generally bring depression in their train. It is better policy to establish such a habit of heat-production as shall render the supply equal to all probable demands. This can be most readily accomplished by the use of the cold or tepid bath—as a stimulant to reaction, not a heat-abstractor and depressant,—and by the avoidance of such wraps as, while they minimise the loss of heat, obviate the necessity for a large habitual production. A volume might be written on this subject of temperature regulation, and a volume *must* be written if the whole truth about the nervous and other forms of force concerned in the maintenance of vitality is to be told; but what has been said will suffice for the hint we are, at the moment, concerned in offering.

THE REQUIREMENT OF GREEK IN THE PREVIOUS EXAMINATION AT CAMBRIDGE.

A DISCUSSION took place in the Arts Schools at Cambridge on Tuesday, Oct. 26th, on the report of an influential Syndicate, which had been appointed to consider a memorial sent by schoolmasters and teachers, including the headmasters of Eton, Winchester, Westminster, St. Paul's, Harrow, and Rugby, Matthew Arnold, C. Darwin, Sir J. Hooker, Professor Huxley, Professor Tyndall, Dr. Vaughan, and the Bishops of Exeter and Winchester. The memorial stated that "the present regulations, according to which a knowledge of Greek is required from all candidates for the Previous Examination at Cambridge, have the effect of excluding a large and increasing number of able and deserving students from the benefits of university education," and it respectfully prayed that the University would be pleased to take into consideration some means whereby candidates for an honour degree may be relieved from the obligation of passing an examination in Greek.

After much deliberation and inquiry, the Syndicate reported—(1) in favour of the relaxation of the requirement of Greek in some cases; (2) that the relaxation should be restricted to candidates for honours; (3) that a knowledge of French and German should be accepted as a substitute for Greek.

THE ABSORPTION OF SNAKE-POISON.

A COMMUNICATION to the Académie des Sciences by MM. Couty and Lacerda illustrates a source of fallacy in the estimation of the virulence of certain snake poisons. Bothrops jararaca is a small snake reputed to be but slightly venomous. They have found, however, that its poison introduced into the blood is very active, while they have ascertained that when introduced into the cellular tissue, it produced but slight toxic symptoms, apparently in consequence of the slowness and difficulty with which it is absorbed. Local symptoms of irritation are much more

marked than general symptoms. Inflammation and local abscesses were caused, but no symptoms similar to those which followed its introduction into the blood, although the subcutaneous dose was five or six times as great as that which had determined toxic symptoms when introduced into a vein. The local inflammation produced was always of a low order—phlegmonous abscesses beneath the skin, or in the muscles; hæmorrhagic pneumonia or pleurisy, when the injection was into the lung; meningo-encephalitis when into the brain, and some of these lesions by their violence caused death, but never the specific effect which was found to follow injections into the subcutaneous tissue. Another interesting fact which was ascertained is the tolerance exhibited by the stomach. The only visible lesions produced there were a few spots of extravasation in the small intestine, scarcely ever in the stomach, and this even although the dose introduced into the stomach is six or ten times greater than that which, introduced into the blood, would be immediately fatal, and introduced under the skin would cause an enormous abscess. But in some of these cases in which the alimentary canal suffered so little, certain distant lesions were found—endocarditis, scattered pneumonia, and some fatty degeneration of the liver.

CROSSED PARALYSIS OF THE SYMPATHETIC.

A REMARKABLE effect of removal of the superior cervical ganglion has been observed by MM. Dastre and Morat. Their experiments, made upon dogs, related not only to the effects of removal of the ganglion, but also to those following the division of its chief branches, especially of the intercervical filament. The animals experimented on were examined at different periods after the operation—four days, eight days, and three weeks. Recovery quickly followed the removal of the superior cervical ganglion: the same evening the animal took food in the ordinary manner, and seemed well. Eight days later, the animal having been slightly curarised, the vagus and sympathetic nerves were divided on the side on which the ganglion had been extirpated. If then the central end of the nerve was stimulated, of course no dilatation of the buccal vessels on the same side followed, but there ensued the unexpected effect of dilatation of the buccal vessels on the opposite side; and this effect was arrested by section of the right vago-sympathetic trunk. This demonstrates the path by which this interesting crossed action was produced.

A VETERAN PROFESSOR.

M. CHEVREUL has finished, for the fiftieth time, his lectures at the Museum of Natural History on the Application of Chemistry to Organised Bodies. Each course has consisted of forty lectures, making a total of two thousand in all. M. Chevreul is in his ninety-fifth year, and he is still an indefatigable worker in the laboratory. His father reached the extreme age of a hundred and ten. The American Association for the Advancement of Science, assembled for its twenty-ninth session at Boston, has sent the eminent *savant* a congratulatory telegram expressing the hope that he will be spared to continue his labours until the end of the century.

THE MEDICAL OFFICERSHIP OF ST. MARYLEBONE.

ON Thursday afternoon the vestry by ballot (Mr. Churchwarden Howard in the chair) appointed A. Wynter Blyth, M.R.C.S., F.C.S., to this position; the numbers for the successful candidate being 69 out of a total of 109 present, 4 of whom lost their votes through being a minute or two late.

THE classes in the Medical Faculty of the Aberdeen University were opened in Marischal College on the 27th ult.,

when introductory lectures were delivered by Professor Pirrie (Surgery), Professor Struthers (Anatomy), Professor Stirling (Physiology), Professor Ewart (Natural History), Professor Shand (Practice of Medicine), Professor Davidson (Materia Medica), and Professor Stephenson (Midwifery). The address of Professor Struthers dealt more particularly with the system of medical education and graduation in Scotland compared with those of England. Professor Stirling spoke on Animal Magnetism; while the remarks of Professor Stephenson were directed to the Relations existing between Hospital and University.

DR. ROBERT GREENHALGH, one of the consulting physicians of the Samaritan Free Hospital, has just presented to that institution a portion of his medical library, consisting of 600 volumes, together with his obstetric instruments. The books are given with the view of forming the nucleus of a permanent library for the use of the staff. We think that Dr. Greenhalgh has done a good work by thus bestowing his books in order that his colleagues may have the opportunity of using such a valuable collection. We need scarcely add that the committee of the Samaritan Hospital have most cheerfully accepted Dr. Greenhalgh's gift, and are making suitable arrangements for the proper care of the books and instruments.

THE death is announced on the 25th ult. of Anthony Beale, Esq., late Surgeon-Major Bengal Medical Establishment. Mr. Beale was educated in Edinburgh, and entered the East India Company's service soon after obtaining the diploma of the College of Surgeons. He served through the Punjab campaign in charge of a battery of Bengal Artillery, and was for many years surgeon on the personal staff of the Governor-General, Lord Canning, whom he accompanied to England after the Mutiny. Mr. Beale retired from the service in 1859, and for many years has resided in Royal-crescent, Cheltenham, where his death took place very suddenly and unexpectedly last week. Mr. Beale was unmarried.

A NEW district hospital, designed for twelve beds, has been opened at Shepton Mallet. The new building stands upon a plot of ground about an acre in extent, and about 100 yards from the old hospital. The design is Gothic, and the material used is stone from a quarry in the neighbourhood, with Bath stone dressings. The construction and arrangements of the edifice are spoken of favourably.

THE death of one of the sisters of charity from diphtheria, contracted during attendance upon the sick of the disease, is announced from Poltava. She was a member of the third detachment of sisters sent by the Red Cross Society to the relief of that district during the still persisting epidemic.

THE entries of students at Owens College, Manchester, this session are as follows:—First year's students, 54; second year's, 57; third and fourth, 75; for partial courses, 25; total, 211.

A CLASS is to be formed at the Military Female Hospital, Chatham, under the superintendence of the Principal Medical Officer of the district, for the purpose of instructing the soldiers' wives in midwifery and general nursing.

THE following gentlemen are candidates for the vacant office of Assistant Physician to the Middlesex Hospital: Dr. Biss, Dr. Burnet, Dr. G. C. Henderson, Dr. C. Hood, and Dr. Wm. Murrell.

A COURSE of stenography has been organised at the Academy of Medicine, St. Petersburg, and one hundred students have intimated their intention of following it.

DR. B. W. RICHARDSON, F.R.S., has been elected to fill the vacancy on the London School Board, caused by the death of Mr. Watson, one of the representatives or Marylebone.

DR. BELL FLETCHER has been appointed President of Queen's College, Birmingham.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

THREE reports have been issued from the Medical Department of the Local Government Board, all from the pen of Dr. H. F. Parsons, and referring respectively to the Llanelly Urban Sanitary District, the Pontardawe Rural Sanitary District, and to the Stourbridge Registration District. Each of these reports will require brief consideration.

Llanelly.—This report is of peculiar interest, as illustrating the progress of sanitary improvements among a large industrial population. Llanelly has been the subject of four official sanitary inquiries. It was inspected on behalf of the General Board of Health in 1850, by Mr. G. T. Clark; again in 1866, under instructions from the Privy Council Office, by Dr. Hunter; still again, and also from the Privy Council Office, by Mr. Netten Radcliffe in 1870; and now, for the fourth time, by direction of the Local Government Board, by Dr. H. F. Parsons. These several reports enable us to follow the sanitary history of the place somewhat closely from the period of the unreformed state of the district to the present time. Dr. Parsons' inquiry appears to have been called for by an undue prevalence of scarlet fever and "fever" in the town; but although this close attention of the Government would seem to imply that Llanelly was particularly in need of exterior incentives to induce it to carry out properly its sanitary functions, on the whole it would seem that, having regard to the circumstances of the place, the local authority has been far from neglectful, and, under considerable difficulties, has effected great changes. Systematic and costly works of sewerage and water-supply have been carried out, leaving few parts of the district now to be provided for. At the time of Mr. Radcliffe's inspection in 1870, 8400 yards of sewers had been constructed; now 32,000 yards exist. Again, in 1870, the water-supply consisted of 8,000,000 gallons held in reserve, and a temporary supply derived from the river Llidi, the waters of which were intercepted and distributed by gravitation to the town. Now the valley of the Llidi has been dammed, and a reservoir formed holding 160,000,000 gallons, admitting of a much larger and more detailed distribution of water in the town. Further, at the time of Mr. Radcliffe's visit it was estimated that five-sixths of the population used common privies, or adopted other and less formal means for the deposit of their excrement. Now, 1530 houses are provided with waterclosets, 836 with pail-closets, 616 with the common privy, and only 169 are without any appliances of this sort. Corresponding advances appear to have been made in the general cleansing and cleanliness of the town. Dr. Parsons shows that these great changes have probably been followed by equally great changes in the prevalence of "fever" in the town, for unfortunately, from peculiarities in the district, the data do not exist which would enable an accurate opinion to be formed on this score, and on the mortality of the place generally. But Llanelly has always had an ill reputation for fever; and Dr. Parsons' inquiry proves that this still in a measure continues, and would seem to throw doubt upon the efficacy of the sanitary measures which have been adopted by the local authority. This, however, is far from being the case. A careful inquiry into the conditions under which the more recent cases of fever have occurred leaves little doubt that the fever of the district is enteric fever, and that it is dependent upon favourable conditions in particular houses. In other words, these conditions, although they have been largely ameliorated

throughout the town generally, have been far from eradicated. The first steps which had to be taken were to make provision for the effectual sewerage, water-supply, and filth-removal of the town. Until this was done the detailed abatement and prevention of the recurrence of nuisances in individual houses could not be carried out. Now that the fundamental sanitary requirements of the town have been virtually completed, it has become possible to deal effectually with individual houses in detail, and this is the kind of work which is now more particularly required from the local authority, and which is needed to give full effect to the measures previously carried out. It is no reflection upon the local authority to say that this detailed work is in arrears, not only as it concerns the local conditions provocative of enteric fever, but as regards the prevalence of infectious diseases generally. Reports, such as this report of Dr. Parsons on Llanelly, are invaluable to local authorities, enabling them clearly to see the position in which they stand with regard to their various efforts at sanitary improvement, and showing, from the health aspect, in what respects these efforts need to be amended or supplemented.

TYPHOID FEVER AT BURLEY-IN-WHARFEDALE.

We have been favoured with the following particulars of the recent outbreak of typhoid fever at Burley-in-Wharfedale, a village where the Rt. Hon. W. H. Forster, the Chief Secretary for Ireland, resides. The first case came under observation on the 19th September and was followed by eighteen other cases from that date to the 13th October. Of these eighteen cases three ended fatally. All the cases occurred among the wage-earning classes. The cause to which the outbreak is assigned was the foul condition of the ashpits and privies in connexion with the cottages. In Burley there is, it seems, no systematic cleansing out of these places, although the attention of the Local Board has been repeatedly called to the subject. The duty of attending to the emptying of the ashpits and privies has been thrown upon the occupier, quite irrespective of his ability to secure such emptying so as to avoid or prevent nuisance. As a consequence there has been terrible neglect, in the face of which both the occupier and the Sanitary Authority appear to have been helpless. In a recent inspection it was found that some of the ashpits and privies had not been cleansed for eighteen months, and the usual practice would appear to be to cleanse them once every year in October, when it suits the convenience of neighbouring farmers to cart away the accumulated filth. The occupiers, in fact, have to depend upon the farmers for the cleansing of the ashpits and privies, and the farmers are not prepared to carry out the cleansing except when they want the accumulated filth for deposit on their fields as manure. The cleansing, in other words, has to be carried out, as a rule, not with reference to the health of the community, but with reference to the fertilisation of the adjacent lands. The ash- and privy-pits are improperly constructed, and admit of the collection in them of much foul liquid. It is complained that, although covered in, they are not ventilated, but it is obvious that either rain finds its way into them, or that "slops" are deliberately thrown in, and that in either case the essential requisite of a common privy, if it is to be used with the least degree of nuisance—namely, dryness of the contents—is set aside. Until this requisite is secured, ventilation of the ash- and privy-pit becomes of secondary importance. The cottages to which these barbarously-constructed out-offices are attached are described as "very handsome," and when it is added that the offices were designed by the architects who also designed the cottages, their hopelessness from a sanitary point of view follows almost as a matter of course. The pits have drains, and their offensiveness must necessarily be extreme. The water-supply of Burley, derived from moorland springs, is exonerated from all suspicion of having any part in the determination of the fever.

THE ARREST OF INFECTION.

A case of no little importance with reference to the arrest of infection was heard before the stipendiary magistrate at Liverpool, Mr. Raffles, on the 20th inst. A woman, the keeper of a provision shop, was summoned by the Health Authority for exposing herself to the public in clothing which had been in a position liable to become infected. The summons was laid under the 126th section of the Public Health Act, 1875. It was stated in evidence that on the 15th inst. the defendant was serving customers in her shop, having at

the same time four children suffering from scarlet fever, and whom she was nursing personally. She was warned not to attend the shop, and it was intimated to her that it should be shut up. Further evidence was produced with a view of showing that the clothing which the woman wore would, under the circumstances, be infectious. Mr. Raffles observed that he did not see that the case came under the section of the Public Health Act referred to, and the solicitor who conducted the prosecution remarked that that was his own view, and that there was no law to meet these cases. The authorities were very anxious to stop the disease in the way observed in this case, and he hoped they would be in a position next time Parliament met to obtain a provision which would prevent one of the most dangerous practices that could prevail in a town like Liverpool. We wish that these remarks had been continued, so as to give some indication how the difficulty was to be met of compensating or of preventing actual pauperism of petty shopkeepers, who would have to cease attending upon their business under circumstances similar to those occurring in this case. Does the Liverpool authority propose to make the alternative of removal of the cases to a hospital indiscriminate in its application?

The public health committee of the Aberdeen Local Authority recently determined to recommend that a clause should be inserted in the Bill which is to be applied for by the Town Council in the ensuing session of Parliament to the following effect:—"In order to secure more prompt action in dealing with infectious diseases, every medical practitioner practising within the burgh shall, within twenty-four hours of the same coming to his knowledge, report to the local authority every case of cholera, small-pox, measles, scarlet fever, scarlatina, diphtheria, typhus fever, enteric fever, and whooping-cough occurring in his practice, and stating the house or place where the patient is being treated, under a penalty not exceeding forty shillings; and if it be found on inquiry by the local authority that the diagnosis of such practitioner was correct, such practitioner shall be paid by the local authority a sum not exceeding two shillings and sixpence for every such case so reported and verified; and in order to facilitate the making of such reports, every such practitioner shall, from time to time, be furnished, on application to the local authority, with printed forms stamped for postal transmission; provided always that the local authority may, from time to time, alter and vary the list of diseases of which such reports shall be made." The council agreed to this recommendation, and granted authority to carry out the object in view.

Mr. N. C. Collier, the medical officer of health for Fulham, in his report for the third quarter of the year, speaks favourably of the health of his district. Writing of the individual who was sent to prison, at the instance of the Sanitary Authority, for refusing to quit a house unfit to live in, in accordance with a magistrate's order and after thirty-six applications to the police-court, and who unfortunately died in prison, Mr. Collier observes: "Surely the comfortable ward of a prison infirmary was preferable to a house containing nothing but an atmosphere reeking with stench. It was not known as a fact that he was ill. Had he complained to the warrant officer he would have been at once taken to a hospital or workhouse." With reference to reported typhoid fever at the Wormwood Scrubs Prison, Mr. Collier states that he has been unable to discover any sanitary defect on the premises, but confirms the report of the prison being exposed to nuisance from piggeries.

At a public meeting recently held in the Mission Hall, Great Arthur-street, St. Luke's, resolutions were passed asking the Home Secretary to introduce a Bill amending the Artisans and Labourers' Dwellings Improvement and Streets Improvements Acts, so as to enable the Metropolitan Board of Works and the Commissioners of Sewers to build proper dwellings to accommodate the labouring classes displaced by the carrying out of the Acts; regretting the action of the Metropolitan Board in refusing to seek Parliamentary powers to effect this object; and calling upon the Board to request the Peabody Trustees to fulfil at once their engagements relating to the Whitecross-street improvement scheme. A further resolution was passed approving of the action of the Local Rights Association in endeavouring to obtain proper dwellings for the people; and expressing a hope that a deputation would wait upon the Home Secretary urging upon him to take further action in this matter.

Colonel Bolton, the water examiner, in his report on the state of the water-supply of the metropolis for August, says that the water of the Thames at the intakes of the several companies who take their supplies from that source was good from the 1st to the 13th Sept., when it became bad, and continued so until the 25th. After that date it was good for the rest of the month. The filtration to which the water was subjected before delivery for use failed to free it "from the effects of the organic matters, principally arising from vegetation brought down by the flood waters."

Dr. Stevenson, the medical officer of health for Paddington, has written to *The Times*, and, in view of the recent outbreak of scarlet fever in his district, determined by infected milk, and of the prevalence of the disease in rural districts from which the metropolitan milk-supply is in part derived, he advises that, during the coming winter, all milk used in the metropolis should be boiled. With regard to any objection which may be urged on this score, he states that it is the usual practice to boil milk before drinking it in France, Germany, Switzerland, and India.

The magistrate of the Southwark Police-court has granted a summons against an official of the vestry of that district for having removed and destroyed a feather bed, the property of a poor woman, on which a case of scarlet fever had been treated, no compensation having been made. The bed was removed ostensibly for disinfection, but destruction was substituted for disinfection. It was complained also that the bed, although the feathers had been put into a clean tick after the recovery of the case, had been carried away in a slop-cart.

The Thames Conservators recently took proceedings against the Wokingham Rural Sanitary Authority for permitting sewage to flow into the Kennet from a sewer into which opened the drains of six or eight houses. The case was heard at quarter sessions, when it was contended that the sewer was a private one, not under the control of the Sanitary Authority. The contention was accepted by the Bench, but a case was granted for a higher tribunal, the decision of the magistrates involving questions of very considerable importance with reference to sewers in rural sanitary districts.

Blandford, it would appear, has neither a proper water-supply nor proper sewerage, and its Local Authority turns a deaf ear to the remonstrances not only of its own ratepayers but even of the Local Government Board. It is reported that the Central Authority, finding written communications ineffectual, has declined further correspondence with the Local Authority, and intimated that the responsibility for any mischief arising from the insanitary condition of the place would rest with them. This is not the usual course adopted by the Local Government Board when default of sewerage is in question.

The surprisingly low death-rates in some of the suburbs of London is deserving of comment. Surbiton has recently reported a death-rate of 8.4 per 1000 of its estimated population, and last year its death-rate averaged only 11.4. Putney, moreover, has lately reported a death-rate of 10.9. Surbiton, however, we learn, is determined to have the health in the future even better than in the present, for it has adopted by-laws relating to new buildings on the model of those suggested by the Local Government Board.

One of the Harbour Trustees of Barmouth, Mr. Wm. Jones, has withdrawn his name from the Trust, in consequence of the Local Board persisting, with the assent of his colleagues, in their intention to carry the drainage of the town into the harbour, and its having been represented to the Local Government Board that he was an assenting party. Mr. Jones has protested against this intention, believing that it will be an injury to the place by proving mischievous to the health of the East-end, and deterring outsiders from visiting it.

The Town Council of Beccles have adopted a report of the Sewage Committee recommending that the plans of Mr. T. Miller, C.E., be carried out for the utilisation of the town sewage, and that forty-five acres of land belonging to the Corporation, situated near Puttock-hill, be devoted to that purpose.

A suggestion has been made to the Mayor of Plymouth by Dr. Pearce and others, to plant the West Hoe and convert it into a garden, in the interest of the health of the inhabitants of the town.

Mr. G. Weston, the superintendent of the works department of the Paddington Vestry, after an inspection of the method of burning of town refuse followed in Leeds, has recommended his Vestry to adopt the same method for dealing with the Paddington refuse.

An immunity from zymotic diseases in Padstow during the past twelve months is attributed to an efficient ventilation of the sewers carried out not long ago.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality showed no further increase last week, notwithstanding the unseasonably low temperature that prevailed. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4830 births and 3244 deaths were registered last week. The births were 355 and the deaths 31 below the average weekly numbers during 1879. The deaths were within five of the number in the previous week, and were equal to an annual rate of 22.6 per 1000 of the estimated population, against 21.7 and 22.6 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 19.3 in Bradford, 20.1 in Leeds, 21.3 in Newcastle-upon-Tyne, and 21.4 in Sheffield and in Portsmouth. The rates in the other towns ranged upwards to 25.3 in Salford, 25.5 in Norwich, 26.3 in Brighton, 26.9 in Liverpool, and 27.5 in Hull. During the past four weeks of the current quarter the death-rate in these towns averaged 22.1 per 1000, against 20.7 in the corresponding periods of the four years 1876-9.

The deaths referred to the seven principal zymotic diseases, which had steadily declined from 1239 to 472 in the nine preceding weeks, were last week 473; of these, 167 resulted from scarlet fever, 119 from diarrhoea, 63 from whooping-cough, and 47 from fever, principally enteric. The annual rate from these seven diseases averaged 3.3 per 1000 in the twenty towns, and ranged from 1.8 in Norwich to 6.3 and 6.4 in Sunderland and Leicester. The 167 deaths from scarlet fever showed a further increase upon the numbers in recent weeks, and exceeded the number registered in any previous week of the year; this disease showed the largest proportional fatality in Sunderland, Leicester, and Oldham. Measles was most fatal in Salford and Leicester. The highest death-rates from enteric fever occurred in Leicester, Salford, and Leeds. Of the 18 deaths from diphtheria, 10 were recorded in London, 2 in Birmingham, and 2 in Sheffield. The fatality of diarrhoea showed a further decline, but still exceeded the average for the season. Two more fatal cases of small-pox occurred in London, but not one in any of the nineteen other towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily declined from 116 to 77 in the five preceding weeks, rose again to 105 on Saturday last; no less than 38 new cases of small-pox were admitted to these hospitals during the week, against but 16 and 12 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 323 in the seven preceding weeks, further rose to 333 last week, which, however, exceeded the corrected weekly average by but 7; 232 were attributed to bronchitis, and 66 to pneumonia. The annual death-rate from lung diseases was equal to 4.7 per 1000 in London, and 6.5 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 24.2 per 1000, against 22.4 and 19.6 in the two preceding weeks, and were 1.6 per 1000 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 14.2 and 20.6 in Leith and Aberdeen, to 29.5 and 44.8 in Greenock and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 135 and 107 in the two previous weeks, rose to 149 last week; they included 51 from scarlet fever, 34 from diarrhoea, 28 from diphtheria, 16 from whooping-cough, 13 from fever, 7 from measles, and not one from small-pox. The annual death-rate from these

seven diseases averaged 6·0 per 1000 in the eight towns, and was no less 2·7 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the eight Scotch towns ranged from 1·9 and 4·0 in Perth and Aberdeen to 7·1 and 10·5 in Leith and Greenock; scarlet fever was exceptionally fatal in Leith, and the high zymotic rate in Greenock was principally due to whooping-cough and diphtheria. The fatal cases of scarlet fever in the eight towns, which had been 52 and 47 in the two preceding weeks, rose again to 51 last week, of which 26 occurred in Glasgow, 14 in Edinburgh, and 8 in Leith. The 13 deaths from fever, of which 8 were recorded in Glasgow, showed a further decline from those returned in the previous week. The deaths referred to diarrhoea, which in the six previous weeks had steadily declined from 69 to 14, rose again last week to 34, and showed a marked excess upon the average number in the corresponding weeks in recent years; the largest proportional fatality occurred in Dundee. The 28 fatal cases of diphtheria included 9 in Glasgow, 7 in Edinburgh, and 4 both in Greenock and Paisley. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 66, 98, and 120 in the three preceding weeks, were 121 last week; the annual death-rate from these diseases last week was equal to 4·8 per 1000 in the eight Scotch towns, against 4·2 in London.

HEALTH OF DUBLIN.

After a slow but steady decline in the rate of mortality in Dublin extending over several weeks an increase was recorded last week. The annual death-rate in the city, which had continuously decreased in the six preceding weeks from 39·3 to 33·7 per 1000, rose again last week to 34·8. During the past four weeks of the current quarter the death-rate in the city has averaged no less than 33·5 per 1000, against 20·8 in London, and 21·7 in Edinburgh. The 210 deaths in Dublin last week showed an increase of 13 upon those returned in the previous week, and included 36, or 17 per cent., which were referred to the seven principal zymotic diseases, corresponding with the number returned in the previous week; 13 resulted from scarlet fever, 10 from diarrhoea, 6 from fever, 6 from whooping-cough, 1 from measles, and not one either from small-pox or diphtheria. The annual death-rate from these diseases was equal to 6·0 per 1000 in Dublin, while it did not exceed 3·0 in London, and was 6·3 in Edinburgh. The 13 deaths from scarlet fever were within 3 of the number in the previous week; the fatal cases of diarrhoea, however, which had steadily declined from 44 to 7 in the five preceding weeks, rose again to 10 last week, and exceeded the average number in the corresponding week of recent years. The deaths referred both to whooping-cough and fever showed an increase upon the numbers in the previous weeks. The annual death-rate from fever (principally enteric), which had averaged rather less than 1 per 1000 during last quarter, has been equal to 1·1 per 1000 during the past four weeks. The deaths of infants showed a further decline last week from recent weekly numbers, whereas there was a marked increase in the number of deaths of elderly persons, owing probably to the large number recorded in public institutions.

REPORT OF THE LOCAL GOVERNMENT BOARD.

II.

THE observations of the Report on the Sale of Food and Drugs Act of 1875 are of unusual interest. It would appear that a considerable number of additional authorities have availed themselves of the advantages to be derived from a compliance with the provisions of this Act in regard to the appointment of an analyst. The number of authorities who had appointed analysts to the time of the report was 237, including the county authorities generally and a large majority of the boroughs. The number of analyses made during the year was 17,049, exceeding by 850 the number made during the previous year. The number would, no doubt, have been greater had it not happened that in a large number of districts the Act had been practically sus-

pended by a doubt being entertained whether articles purchased for the purpose of analysis came within the meaning of the words "to the prejudice of the purchaser," contained within the 6th Section of the Act. In the end, however, a decision of the High Court of Justice, to the effect that the words in question did not, as had been contended, defeat the object of the Act, set the doubt at rest; and since this the decision has been embodied in an Amendment Act.

The articles most commonly found to be adulterated, taken in the order of adulteration from the highest to the lowest, so far as number of adulterated samples are concerned, were gin, spirits other than gin, drugs, milk, mustard, coffee, and butter.

With respect to spirits, the adulteration was of an innocuous character, water only being usually added.

As regards *drugs*, the remarks of the report are so important that we give them in detail:—"We regret to find that drugs continue to be largely adulterated, no less than 171 samples being reported against out of 613 submitted to analysis (25·4 per cent.). One result of adulteration of drugs is, that a person habituated to the use of a certain medicine in an adulterated state may be seriously affected by suddenly taking the genuine article. Thus 'paregoric' is a popular domestic medicine, practically identical with the official preparation formerly called compound tincture of opium, of which opium is the leading ingredient. Certain samples, however, of so-called paregoric, which were analysed in Derbyshire, contained no opium whatever, and large doses might be habitually taken without producing the sedative effect desired, whereas, if the patient were suddenly supplied with genuine paregoric, and were to take it in the quantities to which he had been accustomed, the change might be attended with unexpected and probably disastrous results. Similarly, in the case of sweet spirits of nitre, some samples were found entirely destitute of the nitrous ether, which is the most important constituent of the real compound; and others were diluted with amounts of water varying up to 40 per cent. of the whole. Cream of tartar has been found largely mixed with sulphate of lime; and tartaric acid with lead in quantity sufficient to injure health. Fluid magnesia has been reported to have only 3·3 grains of magnesia per fluid ounce, instead of 5 grains, which is its proper proportion; and tincture of rhubarb bought at one shop has been found of scarcely more than half the strength of that bought at another. We must repeat the opinion which we have expressed in former years, that this state of things demands serious attention, and that strong efforts should be made to secure the sale of genuine drugs of proper strength."

With respect to *milk*, although the number of samples found to be adulterated was large, it was less than in the previous year. Thus the percentage of adulteration had sunk in the provinces from 21·6 in 1878 to 19·4 in 1879; and in the metropolis from 25·4 to 23·3. The proportion of adulterated samples of milk varies much in different districts. This is very marked in the metropolis, and it is not clear how far these differences represent the relative advantages and disadvantages of the respective districts as regards milk-supply, or to what extent they depend on the system adopted of procuring samples, or on other conditions. Generally the adulteration consists of simple dilution with water; but sometimes chemistry is called in to aid in the adulteration, as in the case of a sample where just such an amount of sugar has been added as would bring the sample up to the specific gravity of genuine milk; or where an alkali has been introduced to conceal the badness of milk that has become sour.

The entire money loss sustained by the consumers of milk, to say nothing of the loss of nutriment, by the addition of water, must in the aggregate be enormous. The following attempt at an estimate of this loss for London is given:—"If we assume that in London each person consumes only two pints of milk weekly, or rather over a quarter of a pint daily (and this considering that over one-eighth of the entire population consists of children under five years of age, is probably a moderate estimate), the yearly consumption of the metropolis alone will be found to amount to nearly twenty-three million gallons a year, representing, at 5d. a quart, an expenditure not far short of two millions sterling. If nearly a quarter of this milk be adulterated with about 16 per cent. of added water (and this seems, from the analysts' reports, to be the average proportion), it follows (on the hypothesis that the samples analysed are fairly representative of the entire supply) that Londoners are paying between £70,000 and £80,000 a year for water sold under

the name of milk. This unremunerative outlay might certainly be diminished with advantage by the more extended use of the Sale of Food and Drugs Act."

It is further observed that persons who adulterate are not likely to be very particular as to the quality of water which they use for the purpose; and this is the more important, considering the part which water has frequently been shown to play in the dissemination of infectious disease.

The preparations ordinarily sold as mustard consist for the most part of mixtures of mustard flour, wheat flour, and a little turmeric, and so long as they are not palmed upon the purchaser as genuine mustard there is little to object to in them. The percentage of adulterated samples of coffee continues high, mainly from the practice of selling mixtures of chicory and coffee without adequate notice to the purchaser. In respect to butter, the substitution of "butterine" (a preparation made from beef-fat, mixed with milk and colouring agents, and churned), for the genuine article is seemingly on the increase. Opinions differ as to the wholesomeness of the preparation. The report quotes the following opinion of a public analyst of "high reputation" in this country, namely, that "genuine butterine, which can be purchased retail at less than one shilling a pound, is often more palatable and more digestible than the inferior Canadian and other butters which are washed up, and prepared for the English market, and sold at a little higher price." But, alas! the procuring even of genuine butterine appears to be not unattended with difficulty.

THE SERVICES.

Surgeon Macnamara is mentioned by the late General Brooke, in his despatches reporting the disaster at Maiwand, as having done very good service in attending the wounded during the retreat to Kandahar on that ill-fated day.

Deputy Surgeon-General A. Smith, C.B., late Principal Medical Officer of the Cabul Field Force, has arrived in England invalided for disease of the liver contracted during the campaign.

The appointment of Head of the Statistical Branch, War Office, Whitehall Yard, is vacant by the decease of Deputy Surgeon-General B. Tydd on the 24th ultimo.

MILITIA MEDICAL DEPARTMENT.—The undermentioned officers resign their commissions; also are permitted to retain their rank, and to continue to wear their uniform on retirement:—Surgeon-Major Edward Tweddell Atkinson, North York Militia, dated 3rd November, 1880; Surgeon-Major Joseph Marshall Lynn, Armagh Militia, dated 3rd November, 1880.

ADMIRALTY.—Staff-Surgeon Charles J. Fennell to the *Téméraire*; Staff-Surgeon John Malvany to Portsmouth Dockyard, in lieu of a surgeon; and Staff-Surgeon James Boadley to the *St. Vincent*, in lieu of a surgeon. Mr. Francis G. Wright has been appointed Surgeon (additional) to the *Duncan*. George H. L. Bankier and John A. MacMunn, M.B., surgeons, to the *Duke of Wellington* (additional), for temporary service at Haslar Hospital; and Joseph Crossley, M.D., surgeon, to the *Royal Adelaide* (additional), for temporary service at Plymouth Hospital.

Surgeon James C. Howard has been appointed Surgeon and Agent at Dungarvan and Ballynacourt.

Correspondence.

"Audi alteram partem."

FISH-EATING AND LEPROSY.

To the Editor of THE LANCET.

SIR,—In your journal of Oct. 30th Mr. James Startin records a case of leprosy with some comments on the hypothesis that fish-eating is the cause of that disease. He says that his case "could not possibly be ascribed to the eating of bad fish, for he [the patient] had none." Now, it so happens that I had made a note respecting the same case as supporting the fish hypothesis. I saw the man at the meeting of the Pathological Society, where Mr. Startin produced

him and put to him the questions: "Are you fond of fish?" "Yes, very." "Did you eat fish in India?" "Whenever I could get it." He had been a soldier and had lived in various parts of India where leprosy is endemic. Those who believe that leprosy is due to some poison taken into the system in connexion with fish by no means think that it is necessary under all circumstances to eat fish largely. It is thought probable that in some cases small quantities of fish of a bad kind (and we especially suspect fish in hot climates and all fish that has been potted) may produce an effect which requires large quantities of less unwholesome kinds. I am well aware that such a suggestion is very difficult of credence to anyone who has not studied the facts of leprosy widely. I never yet met with a leprosy patient who did not deny at once that he had ever eaten bad fish, or who was even inclined to admit that he had eaten fish of any kind or in any quantity likely to make him ill. Usually, I believe, I have failed, even after full explanation, to make the patient think that the fish hypothesis was at all probable. The more such patients are questioned the more strongly they repudiate the accusation of having eaten decomposing fish, and the more they endeavour to minimise their admissions as to fish-eating at all. We must collect our facts very carefully if we would avoid being misled. A remarkable example of the risk of error occurred to me last summer. A sharp lad of thirteen was brought to my house by his mother. He was the subject of leprosy, and had lived in India. I put to his mother, in the boy's presence, my usual questions as to fish-eating habits. She told me that her husband was a connoisseur in fish, and always had it on his table when it was obtainable; and she added spontaneously, "This boy follows his father in the taste, and is much more fond of fish than his brothers and sisters." For clinical purposes I admitted the lad into the London Hospital, and gave a lecture on his case, part of which the lad heard. The result was that he told his dresser that he never had eaten any fish, that he had heard a doctor say it was not good for him and never took it. With this revised statement I was confronted at my next visit to the hospital. Which was to be trusted, the boy's statement or his mother's? I sent for his mother again; she positively assured me that he had never abstained from fish until I ordered him to do so, and that in India, for a boy, he had been a large fish eater. Of this, however, I am very sure, that whoever sees that boy in the future will be told by him that in India he never ate any fish.

In the earlier part of his narrative Mr. Startin records of his patient, "He states he had plenty of food, and very little fish; a few sardines and other tinned fish, but this he had only occasionally, and it was fresh." After such an admission, I cannot see how it can be fairly asserted that the disease, "could not possibly be ascribed to the eating of bad fish, for he had none." The man was a common soldier; he had lived thirteen years in India in various parts, and no doubt with very varying opportunities as regards the abundance of fish. I have recorded the man's replies to my questions, and I think that Mr. Startin goes very far beyond the facts when he asks us to accept as proved that none of the fish partaken of in those thirteen years was "bad," in the sense of being unwholesome. I have criticised Mr. Startin's statements at some length because they concern an exceedingly important question, and further because his narrative is a very good specimen of the kind of facts which are adduced to disprove the hypothesis which I with others think probably true. In the freest manner it is asserted of this or that patient who is a leper, "He had never eaten fish," or of some district where leprosy prevails that "fish is never used," but when the facts are sifted they always in my experience turn out to be of the same kind and value as those now before us. Some very remarkable instances of this I felt it my duty to comment on in my College of Surgeons lectures last summer. I have investigated the facts in detail, as much as I have been able; and my present experience is this—that I have not seen a single instance of leprosy in which the fish hypothesis was impossible; nor do I know of a single district where the facts, when sifted, are strongly opposed to it. I know well that there are many isolated cases, and many localities respecting which it seems at first sight improbable, but there are none in which it is impossible. Against the few seeming exceptions we must place the huge mass of evidence in support of this theory which the observations of leprosy in all parts of the world afford. Let any sceptic read Dr. Liveing's excellent lectures, keeping in mind during the perusal what I have ventured to suggest as

the possible potency of small quantities of fish, and the great proneness to exaggeration of statement on the part of many writers. Dr. Liveing himself combats the hypothesis, but I shall be much astonished if anyone can read his book without being strongly impressed with the absence of evidence in support of any other, and the great strength of that in reference to fish.

Before concluding may I ask Mr. Startin to give, either privately or through your pages, the references as regards his assertions as to Rawal Pindi, the Naga Hills, and the Nuggs of Arakan. If he will kindly do so, I will do my best to examine the facts, and will record my conclusions at a future time.

I am, Sir, yours, &c.,

JONATHAN HUTCHINSON.

Cavendish-square, W., Nov. 1st, 1880.

CHOLERA IN INDIA.

To the Editor of THE LANCET.

SIR,—In his report on the cholera history of 1875 and 1876, published a year ago by the Government of India, Dr. Bryden has done me the honour of criticising some statements made in my Punjab Sanitary Reports; and as I find that his observations have been taken as unanswerable in an official report on the cholera of 1878, because they were left unanswered, I shall feel obliged if you will allow me, even at this late date, to make a few remarks on the subject in the columns of THE LANCET. The discussion relates to a matter which deeply concerns the public welfare. The object of Dr. Bryden's remarks is to show that "in dealing with cholera, sanitation must be directed against the inevitable," the statements of mine which he criticises being intended to show that of all preventable epidemic diseases, none can be so readily and effectually prevented as cholera, provided the attack on it be conducted with the requisite skill.

I shall now quote Dr. Bryden's remarks on the statements he has selected for criticism. At page 310 of his report, he writes as follows:—"In 1867 the Meean Meer cantonment suffered heavily; in the great epidemic of 1869 it escaped altogether. The inference was made that the water-supply had been so secured from contamination that the outbreak of cholera in the future was not to be dreaded. The very next epidemic of 1872 swept down on the cantonments, and 185 cases occurred in a strength of 1300, of which 123 were fatal." These remarks refer to the following statement, made at page 17 of my Punjab Sanitary Report for 1868:—"The facts stated leave no room for doubt that there were abundant facilities at Meean Meer for the propagation of cholera through the drinking water, that by the closure of the cesspools those facilities were greatly lessened, and that by the disuse of the wells and their attached open reservoirs those facilities have been almost altogether removed. There are still some grave defects in the water-supply of the station, which, it is to be hoped, will be shortly removed; but even as matters now are, a repetition of the terrible epidemics of past days is impossible." Now, I must admit that in making this statement I fell into two errors—first, I altogether underrated the danger inherent in the grave defects referred to. I considered the disuse of wells situated within leakage distance of deep cesspit latrines a great improvement, but I under-estimated the risks of contamination to which the new source of supply, a small open canal cut, flowing through a thickly-inhabited country, was exposed, as is proved by the fact that the dead body of a native was removed from the cut, where it must have lain some time, only a few days before the arrival of Dr. Cunningham, when he visited Meean Meer to investigate the circumstances of the epidemic in question. Of course, this dead body could have had nothing to do with the causation of that epidemic; but the discovery of it, which was quite accidental, shows how greatly I under-estimated the "grave defects" referred to in the extract from my report above quoted. The second error I made was in under-estimating the force of the obstruction which the scheme then in contemplation for removing the "grave defects" would experience. In my simplicity I believed that the grave defects would be shortly removed, but to my sorrow nothing whatever had been done to remove them when I left the Punjab, seven years after

the prediction, to the failure of which Dr. Bryden refers, was made. But terrible as was the epidemic of 1872, its horrors fell far short of those of 1856 to 1861, which were the ones I had in view when the passage was written. The epidemic of 1861 killed 24 per cent. of the troops; the epidemic of 1872 only 8 per cent. Considering all the circumstances of the case, I do not think that the partial failure of my prediction will be regarded as giving support to Dr. Bryden's thesis, that, as regards cholera, "sanitation must be directed against the inevitable." I adhere to my old opinion, that with a proper water-supply an epidemic of cholera would be impossible at Meean Meer; but at the same time I am by no means sanguine that the projects which have been so long under consideration will realise that happy deliverance.

Dr. Bryden's next observation, to which I desire to reply, is as follows:—"In the epidemic of 1869 the Lahore Lunatic Asylum lost 33 out of a strength of 200 inmates. No other community at Lahore suffered in any such ratio. The conclusion arrived at was that the sand through which the drinking water of the lunatics passed had been impregnated with cholera evacuations. Among the first to suffer in 1872 were these same lunatics. In the epidemic of 1875, out of a strength of 275 lunatics in the asylum, there were 27 cases and 19 deaths. It is not likely that the contingency of sand-poisoning should have occurred in three successive epidemics, and the Sanitary Commissioner for the Punjab does not urge this theory in writing of the outbreak of 1875." Does Dr. Bryden really suppose that there is only one means by which water may become contaminated? Under the system of supply now existing in India, the modes of contamination are infinite in variety. In my report for 1869, referring to the cholera virus, I said that in places "where the water-supply is entirely exposed to excremental pollution, no amount of personal precautions can bar its entrance into the stomach. So multitudinous are the avenues by which it effects a lodgment that it is impossible to guard them all—through the bath, in milk, in butter, on uncooked vegetables, or fruit; and finally, in drinking water it has innumerable facilities for reaching its breeding ground in the stomach and bowels." In 1872, as in 1875, there were many channels by which cholera-matter might have gained access to the stomachs and bowels of the lunatics. My report for 1869 only indicated the channel by which I considered that on that occasion the enemy had effected a lodgment in greatest force.

I shall now only add this: wherever the water-supply of a locality has been placed on a moderately satisfactory footing (unfortunately there are not many such places in India), the liability of the population to cholera has instantly been either greatly reduced or almost entirely extinguished. Everyone knows the truth of this statement as regards Calcutta and Bombay, where the European residents have for the last ten years been nearly as free from cholera as the inhabitants of London. But there are other instances which, if less known, are not less conclusive. Since the municipal water was laid on to Fort William eight years ago, the troops stationed in that once unhealthy place have been almost entirely free from cholera, although the men are still exposed to infection, when, as they will do, they go out into the purlieus of the town and suburbs, and also through milk, which it is next to impossible to get free from adulteration in Calcutta. They have, in fact, been almost as healthy as if they had been quartered in one of the healthiest camps in England. The death-rate for the six years ending in 1878 was only 10 per thousand of strength. The city of Nagpore is another illustration in point. This place was formerly a great sufferer from cholera. In 1871 water was laid on to the town, in iron pipes. There has not been a single epidemic in the town since, although stray cases have occurred from time to time, and the adjacent district has suffered severely on three different occasions. In 1878 there were 3356 cholera deaths in the Nagpore district, and only 69 in the town. In the district the ratio of cholera deaths was 54 in the town, 6 per 10,000 of population. There can be little doubt that many of the cases that occurred in the city contracted the infection in the neighbourhood external to the city. Kohat is another memorable illustration. This place, in Dr. Bryden's system, has a very mysterious importance attached to it as a great cholera focus. He speaks of the terrible outbreak of 1869 among the troops as "the result of a single affluat of the cholera miasm." Certain it is that if, in former days, cholera got into the vicinity of the cantonment, it never failed to commit sad havoc among the troops. And

what is the case now? In 1872 the duct which supplies drinking water for the cantonment, and which is described in the Punjab Sanitary Report "as a lounge for dogs and a receptacle for the surface drainage of the station," was made tolerably safe against contamination. Two epidemics have since visited the locality. The one of 1876 passed over the station quite harmlessly. In 1878 the adjacent town and district suffered severely; but in the cantonment there were only eight deaths registered, and this though the place was crowded with 7000 troops and followers, brought there by the field operations in the Kurru Valley, and was in a very insanitary state in consequence. The last case I shall refer to is that of the emigrant coolies on the Brahmaputra steamers. For nearly twenty years cholera had made terrible havoc among these poor people, in spite of all the efforts of the Bengal Government to prevent it. Four times on each voyage of about eighteen days the arrangements on board the steamers for the coolies were inspected by medical officers of the highest ability, and almost invariably pronounced very good—perfect cleanliness, good food, good clothing, plenty of room, excellent water. But in spite of all these advantages, the dreadful mortality continued from year to year, and it was a common thing for from thirty to sixty dead coolies to be thrown overboard in the course of a few days. All other explanation of these fearful catastrophes failing, it was concluded that the coolies, who mostly belonged to one of the primitive Indian races, had such a strong predisposition to cholera that human efforts were powerless to control it. And the Government had settled down in the belief that it was a struggle with the inevitable. But in the end it turned out that although four times in each voyage the water-supply was pronounced excellent, it was in reality extremely bad. The Bengal Government at length adopted structural precautions, which made it impossible for any but pure water to be used for any purpose whatever; and, behold, the predisposition of the coolies to cholera vanished, and the mortality among them became so small that the Superintendent of Emigration at Dhubri reports that he now finds it inconvenient to record it any longer in centesimal ratios. The results obtained in these cases, harmonising as they do with European experience, teach no doubtful lesson. They show that the struggle with cholera is not the hopeless contest that Dr. Bryden supposes.

In conclusion, let me say that, although I have for years felt it my duty to combat the views put forth on this subject by Dr. Bryden, I feel sure that that officer deserves the nation's gratitude for the herculean labour, under the guidance of brilliant genius, with which he has brought order into the once dreary chaos of Indian medical statistics.

I am, Sir, yours truly,

A. C. C. DE RENZY,
Deputy Surgeon-General, Punjab Frontier Force,
late Sanitary Commissioner, Punjab.

ON THE COMPULSORY INTIMATION OF INFECTIOUS DISEASES IN EDINBURGH.

To the Editor of THE LANCET.

SIR,—At the last meeting of the Social Science Congress I gave the statistics relating to the carrying out of the compulsory intimation of infectious diseases. The Local Act in question came into operation on November 7th, 1879, and up to September 6th of the present year—a period of ten months—no fewer than 4502 intimations had been received by the authorities. These comprised: typhus, 22 cases; typhoid, 226 cases; diphtheria, 127 cases; scarlatina, 917 cases; measles, 3210 cases. In 412 cases the circumstances were such as to justify the removal of the patients to a hospital with the concurrence of the medical attendant.

As your readers are aware the intimations are made by the medical profession, who are furnished with suitable slips and stamped envelopes, and who receive 2s. 6d. for each intimation. Last July a sum of £519 was sent out to the profession, and so convinced is the Corporation of the value of the information thus received, that they have set aside £1000 to cover the expenses of the current year.

Our experiment has been a great success. No complaints have reached us from the medical profession, who have loyally assisted the authorities in carrying out what was feared would be an unworkable and objectionable clause. The

information as to the existence of infectious disease has been prompt and effectual, which, I am convinced, would not have been the case had we trusted in great part to a poor, ignorant population to supply it. No doubt here we enjoy exceptional advantages from the large number of students attending our hospitals and dispensaries, and it is comparatively rare to find a person dying without medical advice. This is mainly due to the custom introduced by myself some twenty years ago, of causing an official inquiry to be made by the police into all cases of death occurring without a medical man seeing the patient during life. This inquiry entails on the relatives considerable annoyance, and has gradually led them to recognise the importance of seeking medical assistance. One of the subsidiary advantages of this procedure is, that the number of uncertified deaths in Edinburgh is very small.

To the health department the intimations have proved of great service—first, in showing how inadequate was the existing accommodation for infectious diseases in our various hospitals; and second, in enabling us to arrive at the true cause of outbreaks of these diseases, and thus prevent their spread.

Yours, &c.,

HENRY D. LITTLEJOHN, M.D.,
Medical Officer of Health.

Edinburgh.

"DENTAL SURGEONS," "SURGEON-DENTISTS."

To the Editor of THE LANCET.

SIR,—As a Fellow of the Association of Surgeons practising Dental Surgery, permit me to offer you my best thanks for the very able remarks contained in your issue of last week relative to the continued abuse of the above-mentioned titles by totally unqualified persons, as well as by such as have merely a licence to practise dentistry from the College of Surgeons. The "Dentists Act," as you justly say, has become a delusion and a snare, but it is some satisfaction to know that but for the opposition this statute met with at the hands of those of us who, being surgeons by diploma, practise dentistry merely as a specialty of surgery, matters would have been far worse than they are now.

Let it not be forgotten that it was due to no want of zeal or activity on the part of the gentleman who framed this measure, that the medical profession was not crippled and harassed by a clause which he strove hard to include in the Dental Bill, making it illegal for qualified medical practitioners to style themselves or pursue their calling as dental surgeons until they had first registered their names on the list of his unqualified friends—friends from whom he has lately received a testimonial. This clause was after some trouble withdrawn, but it leaves no doubt as to the democratic nature of his views.

Again thanking you for the support which on every occasion you have given to those of us who have at heart the best interests of the profession, as well as that of the specialty we practise,

I am, faithfully yours,

W. DONALD NAPIER.

George-street, Hanover-square, Nov. 4th, 1880.

IRELAND.

(From our own Correspondent.)

UP to the present time candidates for the Fellowship of the Royal College of Surgeons in Ireland were permitted to send in applications for examination at irregular periods; but by a recent regulation of the Council it has been determined that for the future all candidates for the fellowship shall undergo examination at the ordinary sessional examinations. Doubts are entertained whether the new method will work as satisfactorily as the older system.

Introductory lectures have been given at several of the medical schools and hospitals in Dublin. Last week Mr. Swanzy, Professor of Ophthalmic Surgery in the Royal College of Surgeons, gave the inaugural address in the Medical School, and Dr. Quinlan at St. Vincent's Hospital; and last Monday addresses were delivered at the Meath Hospital, and Ledwich School of Medicine, by Messrs.

Hepburn and Benson respectively. The session commenced in October, but the strange regulation still prevails of having the introductory delivered in November instead of the early part of the previous month.

The election for Members of Council of the Surgical Society of Ireland took place on the 1st inst., when all the outgoing councillors were re-elected. Thirty-four members of the society recorded their votes.

Compulsory attendance on medical lectures has of late received a good deal of attention, and the Colleges of Surgeons and Physicians in Ireland have recently adopted regulations relative to this subject; while the University of Dublin has a stringent rule to the effect that no certificate shall be granted to any student who does not at all events attend three-fourths of the course delivered. It is, however, one thing to compel a student to attend a certain number of lectures, and quite another to guarantee that he derives instruction from such attendance. Here the various examining boards are at fault, except the Queen's Colleges, which carry out the following arrangement, that guards against an absence from lectures or a merely nominal attendance. For example, a daily roll-call is in force in every class, and class examinations are frequently held, while no credit is given for attendance when deficient preparation for lecture or deficient study of the subject is exhibited by the student. The class-certificate therefore of the Queen's College system not alone shows the payment of a fee and the entry of a name on the class-roll, but is besides a guarantee of continuous study of the subject lectured on on the part of the student during the whole session. The President of the Queen's College, Galway, in his recent report for the past session, draws particular attention to this method, as avoiding the well-known abuses of the lecture system.

A deputation from the Irish Medical Association waited, last Monday, on the Chief Secretary for Ireland with reference to the limitation of salaries of medical officers of health which exists, and also as to the exclusion of public health salaries and lunacy fees in computing retiring allowances for Poor-law medical officers. The scale proposed by the Local Government Board when the Public Health Act of 1874 became law was a maximum of one-fourth of the salary of the dispensary medical officer; but the maximum had been given in very few instances, and the Association were of opinion that even this amount would not admit of adequate remuneration for services zealously performed in most districts. In 1878 the Act now in force was introduced, it being understood that there should be no maximum scale, but that each salary should be decided on its merits; and it was contended that the average salary for medical officers of health was now only about half of the average maximum prescribed by the repealed Act of 1874. The question which the Association wished the Chief Secretary to consider was whether the Treasury had any right or power to enforce the repealed scale; for if it was intended that due effect should be given to the provisions of the Public Health Act, it was desirable that a liberal minimum scale of salary should be fixed, in order that proper and independent supervision should be provided, and that efficient officers should be equitably remunerated. The second subject brought forward was in connexion with superannuation, and it was pointed out that of late the Local Government Board had refused their sanction to a portion of the pension granted to two Poor-law medical officers, stating as their reason for so doing that they had been advised that salaries payable under the Public Health Act and fees for examination of lunatics should not be included in the computation of pensions, inasmuch as they were emoluments which accrued under Acts passed after the latest Superannuation Act. The Chief Secretary, in reply, referred to the important position which dispensary medical officers held throughout Ireland, and the faithful and devoted manner in which they discharged their duties; and observed that it was hard to expect sanitary improvements to be carried out unless the sanitary medical officers were satisfied with their position, and felt they were fairly treated in the matter of remuneration. He felt that a strong case had been made out, and although it was a matter for the Treasury he would promise that the views of the deputation would be considered.

The Visiting Committee of the Guardians of the South Dublin Union have recommended, in reference to Dr. MacCabe's recent report on the management of the Kilmainham Small-pox Hospital, that the clothes of every patient should, on admission, be destroyed, and that a nurse be appointed to each of the hospitals for night duty. The

arrangement of having paid and responsible nurses for irresponsible pauper nurses is a great improvement, and the change will be carried out without delay.

The Committee of the Home for Incurables, Cork, have made an appeal for funds to complete the institution, one of the first of its kind in the United Kingdom. One thousand pounds are at the present time required to pay off existing charges on the building account, and a similar amount to complete the hospital. I have little doubt but that the necessary funds will shortly be subscribed for so deserving a charity.

At a meeting of the Cork Board of Guardians held last week, Dr. Wall reported that a woman named Keegan had been admitted to the Union Fever Hospital on the 25th ult., having been landed that day at Queenstown from one of the American emigrant steamers, and declared to be suffering from small-pox. It eventually proved, however, to be a case of varicella, and the patient was transferred to the shed originally constructed in the workhouse for the reception of small-pox patients, perfect isolation being secured. At the same meeting a deputation from the ratepayers waited on the Cork Board of Guardians and presented a memorial on the subject of the increased amount of stimulants used in the workhouse, but Dr. Callaghan, one of the medical officers, showed that the consumption in the Cork workhouse compared very favourably with the amount consumed in the North and South Dublin Unions. While the cost of stimulants in the former place averaged £10 per week, in the Dublin Unions the expenditure amounted to £25 weekly. After some discussion it was decided to refer the memorial to the medical officers to report on the subject on that day fortnight.

Dublin Hospital Sunday will be held on the 14th inst.

Dublin, Nov. 2nd, 1880.

PARIS.

(From our own Correspondent.)

THE chief event of last week was M. Pasteur's long promised communication to the Academy of Medicine, on the attenuation of the virus of fowl's cholera (*choléra des poules*). The assertions of M. Pasteur are so important that it will be well to give a translation from the official bulletin. It is as follows:—

Of the different results which I have had the honour to communicate to the Academy concerning the affection commonly known as *choléra des poules*, I take the liberty of reminding you of the following.

(1) Cholera of fowls is a disease virulent in the highest degree. (2) The virus consists of a microscopic parasite that can be easily multiplied by culture, outside the body of the animal that the disease affects. Hence the possibility of observing the virus in a state of perfect purity, and the demonstration that it is the sole agent of disease and death. (3) The virus offers various degrees of virulence. Sometimes the disease is followed by death; sometimes, after having given rise to morbid symptoms of variable intensity, it ends in cure. (4) The differences observed in the power of the virus are not only the result of observations of the natural course of things, but can be produced by the experimenter at will. (5) As a rule, in all virulent diseases fowl's cholera does not recur, or rather recurrence happens in a degree which is inversely proportional to the severity of the first infection; and it is always possible to push the preservation so far that subsequent inoculation with the most virulent virus will produce no effect. (6) Without wishing to affirm anything at present as to the relation between variolous virus and human vaccine, it is evident from what precedes that in fowl's cholera there exist states of the virus which, relatively to the most virulent virus, perform the same office as human vaccine does in relation to variolous virus.

Vaccine virus produces a benign disease—vaccinia—which gives immunity from a graver disease, variola. In the same way fowl's cholera has states of attenuated virulence which cause the disease but not death, and in such conditions that the animal can, after recovery, submit to inoculation with a very virulent virus. The difference is great, however, in some respects between the two classes of facts, and it may be well to remark that as regards our knowledge, and our deductions, the advantage is with the study of fowl's cholera: for where

the relations between variola and vaccine are still a matter of controversy, we know that the attenuated virus of fowl's cholera is derived from the virulent virus, special to the disease, that we pass directly from the first to the second; in a word, that their fundamental nature is the same.

The time has now come to explain the chief assertion, which forms the basis of most of the preceding propositions—namely, that variable degrees of virulence exist in the cholera of fowls. Surely a strange result when it is considered that the virus of this affection is a microscopic organism, which can be handled in a state of perfect isolation, as one can experiment with the yeast of beer, or the mycoderma of vinegar. And yet if this mysterious datum of variable virulence is considered calmly, it will be recognised that it is probably common to the different species of this group of virulent diseases.

Where, then, is unicuity in any of the scourges which compose this group? To quote an example, do we not see epidemics of severe variola, and others which are almost benign, without being able to explain the difference by external conditions of climate, or by the constitution of affected individuals? Do we not also see great contagions die out, to reappear later, and again become extinct?

The theory of the existence of variable intensities of the same virus is not then calculated to surprise either the physician or the well-informed, notwithstanding that it is of immense interest that it be scientifically established. In the particular case under consideration, the mystery lies in the circumstance that the virus being a microscopic parasite, the variations in its virulence depend upon the will of the observer. This is what I must establish with certainty.

Let us take as our starting-point the virus of the cholera in a very virulent condition, the most virulent possible, if we may use the expression. I have already made known a curious way of so obtaining it. It consists in collecting the virus from a fowl which has just died, not of the acute, but of the chronic disease. I have observed that the cholera is sometimes seen in this form. Such cases are rare, although it is not very difficult to meet with examples. Under these circumstances the fowl, after a severe illness, wastes away, but keeps alive for weeks or months. When it succumbs, which happens when the parasite, which had hitherto been localised in certain organs, passes into the blood and there develops, it will be observed that whatever may have been the original virulence of the virus when inoculated, that which is extracted from the blood of an animal which has taken long to die, is of considerable virulence, generally killing ten times out of ten, and twenty out of twenty.

This being stated, let us now make successive cultures of this virus, in a state of purity, in a decoction of fowl's muscle, taking each time the germ of the new culture in that which preceded it, and let us try the virulence of these different cultures. Observation shows that the virulence does not change in an appreciable degree. In other words, if we allow that two virulences are identical when, by operating on the same conditions upon the same number of animals of the same kind, the proportional mortality is the same, we also recognise that for our successive cultures the virulence is the same.

Hitherto I have neglected the interval between two successive cultures, that is to say, between one sowing-time and the following. Let us now consider this point, however small it may be apparently. For an interval of from one to eight days the successive virulences remain unchanged. For an interval of a fortnight the same result. For an interval of a month, six weeks, or two months even, no change will be observed in this respect. As, however, the interval increases, a few signs of little apparent value appear to indicate a weakening of the inoculated virus.

The rapidity of death, for example, if not the proportion of the mortality, becomes lessened. In the different series inoculated will be seen fowls which cling to life, very ill, and very lame, for the parasite, in its propagation through the muscles, has reached those of the thigh. The pericardites run a longer course; abscesses appear around the eye; the virus has lost, in fact, its *foudroyant* character. Let us now increase the periods between the successive cultures. Let us extend them to three, four, five, or eight months, and more, before studying the virulence of the development of the new microscopic being. Now the scene will change entirely. The differences in the successive virulences, which were hitherto *nil*, or at the most doubtful, are about to exhibit themselves with considerable effect.

With such intervals between the germ-sowings, we find

upon culture that instead of identical virulences—that is to say, of a mortality of ten fowls in ten inoculations—the mortality falls progressively to nine, eight, seven, six, five, four, three, two, or one, in ten, and sometimes even there is no mortality at all; the disease manifests itself in all the individuals experimented on, and all recover. In other words, by simply changing the mode of culture, by simply separating the periods of germ-sowing, we have a means of obtaining progressively decreasing virulences, and, finally, a true vaccine virus, which does not kill, but communicates a benign disease, preservative from its mortal form.

It must not, however, be thought that in all these attenuations everything happens with a constant and mathematical regularity. One culture which has been kept for six months may still show considerable virulence, whilst another may have become greatly attenuated after three or four months. We shall see the explanation of these anomalies, which are, however, anomalous only in appearance. Sometimes, indeed, there is a sudden jump from a great degree of virulence to the death of the microscopic parasite in a very short interval, and on passing from one culture to another one is surprised by the impossibility of development. The parasite is dead. The death of the parasite is, in fact, a common circumstance, occurring constantly when there is a sufficient interval between the cultures.

And now the Academy is aware of the real motive of the silence which I have hitherto observed, and why I claimed a period of delay before making known my method of attenuation. Time was an element of the question.

In the course of these changes what becomes of the microscopic organism? In changing its degree of virulence in so marked a manner, is there any change of form or appearance? I will not say that there is no morphological relation between the parasite and the different degrees of virulence which it presents, but I must confess that I have hitherto been unable to detect any, and if it exists in reality the extreme smallness of the parasite prevents its recognition by the microscope. The cultures appear the same in all virulences. If slight differences are sometimes seen they would seem to be accidental only, for they disappear, or are produced in an inverse manner, in the next culture.

It is equally worthy of remark that, if one takes each variety of virulence as the starting-point of new successive cultures made at short intervals, each variety of virulence keeps its own special intensity. If, for instance, an attenuated virus only kills once in ten, it keeps this virulence when the successive cultures are not made with too great an interval between the germ-sowings.

Another point is worthy of remark, although it is in strict accordance with what has been observed—viz., that a germ-sowing interval which suffices to destroy an attenuated virus does not kill a more virulent virus, which may perhaps be again attenuated, but which does not then necessarily become extinct.

The important question must now be raised as to the cause of the diminution of the virulence. The cultures of the parasite are necessarily made in contact with the air, for our virus is an aerobe being, whose development is not possible without it. We naturally inquire whether the weakening influence on the quality of the virulence does not reside in the contact with the oxygen of the air. May not the little organism which constitutes the virus, abandoned in presence of pure air, to multiply in a field of culture, undergo a modification, which will remain permanent, even when the organism is withdrawn from the modifying influence?

We can inquire, moreover, whether any other principle of atmospheric air, a chemical or fluid principle, can account for a phenomenon which by its incomparable strangeness warrants every hypothesis.

It is easy to understand that the solution of this problem, should it be explained by our first hypothesis, that of the influence of the atmospheric oxygen, can be easily enough determined by experiment; for if the oxygen of the air is indeed the modifying agent of the virulence, we can easily have the proof by the effect of its suppression.

To this end let us conduct our cultures as follows:—A suitable quantity of decoction of fowl is sown with the seeds of our most virulent virus, and glass tubes are filled to three-quarters of their volume and then hermetically sealed. Owing to the air that still remains the development of the virus will begin, which is seen by an increasing cloudiness of the liquid; the progress of the culture then exhausts all the oxygen contained in the tube. Then the cloud falls, the virus is deposited on the sides of the tube, and the cultivat-

ing liquid clears up. Two or three days are required to produce this effect. The little organism is henceforth uninfluenced by oxygen, and will remain in the same condition as long as the tube is sealed. What will now become of its virulence? To be more sure, let us prepare a large number of such tubes, and, at the same time, an equal number of tubes of the same culture, but freely exposed to the action of pure air. We have said what becomes of these cultures exposed to the contact of the air. We know that they experience a progressive diminution of their virulence: we shall not return to them. Let us speak only of the cultures in closed tubes. If they be opened, one after a month's interval, after having made a culture by the germsowing of a portion of its contents, let its virulence be tried. Let another be opened after two months, and again another after three months, and so on with a fourth, fifth, sixth, seventh, eighth, ninth, and tenth tube at intervals of from two to ten months. There I will pause for a moment. It is remarkable—and experiment proves it—that the virulences are always identical with the original virulence, with that of the virus which was used in the preparation of the closed tubes. As to the cultures which have been exposed to the air, they are always either extinct or else possessed of very feeble virulence.

The question which we have studied is then solved: it is the oxygen of the air which weakens or extinguishes the virulence. This is probably more than an isolated fact, we may here be in possession of a principle. It may be hoped the inherent action of atmospheric oxygen, a natural force which is everywhere present, will be found efficacious in other virus. In any case, the probable grand generalisation of this method of the attenuation of virulence by a cosmic influence is a circumstance which is well worthy of attention. May we not presume henceforth that it is to this influence we may attribute the limitation of great epidemics?

The facts which I have had the honour to communicate to the Academy suggest numerous immediate or indirect inductions. As to these I am bound to the greatest reserve. I shall not feel authorised in publishing them until I am able to announce them as demonstrable truths."

Obituary.

DEP. INSP.-GEN. EDWARD GOODEVE, M.B., Q.H.P.,
LATE BENGAL ARMY.

THE members of the Indian Medical Services, as well as many others in India and at home, will learn with profound regret that Deputy Inspect.-Gen. Edward Goodeve, M.B., late Professor of Medicine, Senior Physician to the Medical College Hospital in Calcutta, and Honorary Physician to the Queen, died on the 27th of October last, at his residence in Stoke Bishop, near Bristol, at the age of sixty-four years. The following brief outline of his career (communicated) conveys but a faint impression of him whose services it so briefly records.

"Dr. Edward Goodeve was born at Bury Hall, Alverstoke, Hants, on Jan. 27th, 1816. He was educated at private schools in England and France, and studied his profession under his brother William, who was a leading surgeon and a teacher of anatomy in Bristol, where he also was a very attentive student at the Royal Infirmary. He then went to London, where he became a dresser, under the late Sir W. Lawrence, for two years at St. Bartholomew's Hospital. Sir William was so much pleased with his pupil that when his work at the hospital was over and he had taken his degree, unsolicited he obtained for him an assistant-surgeon's appointment to Bengal.

"Dr. Edward Goodeve arrived in Calcutta early in 1841, and was shortly afterwards selected as travelling physician to the Bishop of Calcutta, Dr. Wilson, with whom he made several long expeditions. In 1843 he went to Cawnpore as civil surgeon, and remained in that capacity for several years; meantime, however, serving with the British forces in both Sutej campaigns, for which he received a medal and two clasps (Chillianwallah and Guzerat). In 1850 he was appointed Assistant Apothecary-General and Professor of Materia Medica in the Calcutta Medical College. Shortly afterwards he relinquished these offices, and became Professor of Medicine and Physician to the College Hospital—

offices which he held till he retired from India in 1864. In this position he rapidly acquired a large and important private practice. In 1864 he returned to England, and in 1866 he was sent by the Home Government to Constantinople to represent England in the International Cholera Commission.

"On his return to London he established himself as a consulting physician, but his health giving way, he gave up entirely the practice of his profession and retired into the country, finally living during the last few years at Drinagh, Stoke Bishop, a beautifully-situated villa on the banks of the Avon, about two miles from Clifton. He contributed two most valuable articles (on Diarrhoea and Cholera) to 'Reynolds' System of Medicine.' He married twice—firstly, Miss Renoux, of Jersey, in 1842; secondly, Miss Allen, in 1866, but he left no children alive. Some years ago he suffered from a slight attack of paralysis, from the effects of which he never entirely recovered. He had been for a long time in bad health, and though the symptoms were rather obscure, he doubtless sank at last from cerebral affection, seriously injuring his digestive and respiratory functions, and death appeared to be caused by a sudden and violent accession of the disease."

The death of this distinguished medical officer has removed one of the brightest ornaments of the old Indian Medical Service, a most able teacher and accomplished gentleman, one in whom centred all that did honour to the office of physician, and gave grace and charm to the character of friend. His whole career from the day he landed in India was one of marked utility. His military services during the Sutej campaigns were important, and distinguished by as much ready promptitude and skill in surgical operations in the field as by devoted attention to the sick and wounded in hospital.

But it was in Calcutta, during his long connexion with the Medical College and Hospital, as Professor of Medicine and Senior Physician, that his great work was done and his merits became conspicuous. It was there, as a teacher and among the European and native population (for he was equally well known to all), that he acquired the fame that will, in India as well as at home, attach to his name as a physician, and that gave him the high position that he held among his brethren.

Of retiring and undemonstrative nature, his judgment, skill, and knowledge of disease were yet of the highest order, while his powers of diagnosis were only excelled by his skill in treatment. Deeply versed in the knowledge of pathology, and excellent alike as physician or surgeon, he rapidly attained pre-eminence. His most valuable researches on dysentery, diarrhoea, enteric fever, cholera, and the so-called red-fever of Bengal, form the most important of his written contributions to the annals of medicine.

His name still is, and long will be, familiar as a household word in Bengal. His pupils, scattered over India and Ceylon, no less than his colleagues and friends everywhere, will deplore his death, whilst they hold him in grateful remembrance; for no medical officer ever made a deeper mark, none will be longer remembered as a teacher and benefactor of the natives of India, than Edward Goodeve.

In addition to the duties he performed in connexion with the Medical College and Hospital, he was a member and sometime President of the Faculty of Medicine in the Calcutta University, of which he was also a Fellow and an Examiner in Medicine; he was moreover an honorary Physician to the Queen. But besides and above all this, he was the physician in whom all reposed confidence, and was much beloved by all who enjoyed the privilege of his friendship.

His whole life and conduct form a beautiful model, on which a young medical officer might well endeavour to frame his own career.

EDWIN HEARNE, J.P., M.B. LOND., F.R.C.S.

WE have to record the death of Dr. Edwin Hearne, who died at Southampton on the 22nd ult. of apoplexy. Dr. Hearne was born near Taunton in the year 1820. His father was a large farmer, descended from an old Somersetshire family. Dr. Hearne was originally intended for a business career, but his tastes being of a more ambitious nature, he entered as a medical student at University College in 1840. He there distinguished himself by carrying off many class prizes, and in 1844 graduated M.B. at the University of London, taking honours in physiology and comparative

anatomy, as well as in medicine and surgery. He was afterwards house-surgeon at University College Hospital, and was a favourite pupil of Liston. So anxious was he to qualify for the highest position in his profession, of which he was an ardent lover, that he spent some time in studying at the Paris hospitals. On his return he happened to land at Southampton, and was so struck by the improving look of the place that he settled there in 1845 and soon acquired a large practice. He was a most accomplished surgeon and an expert operator. In politics he was a very advanced Liberal, and he worked with heart and soul in the cause. His mind was original and thoughtful, and his temperament vigorous and bold. This continually involved him in scientific and political controversies.

In 1864 the wear and tear of his large practice, combined with his other work, brought on a painful affection of the nervous system, which resulted in torticollis. This obliged him to give up active practice, and he retired to Germany for a time, but by the use of subcutaneous injections of morphia he subdued to a great extent the distortion of the neck, and resumed practice as a consulting physician. His health, however, was never sufficiently re-established for him to do much work, yet he took great interest in social and municipal matters, and became also an ardent sportsman. He was well known amongst hunting men as a straight and fearless rider to hounds; and in *Bailey's Magazine* the "White Doctor," as he is called, is described as a hard man to beat.

Dr. Hearne was a frequent writer, both on medical questions and in the local press. He was for some time a member of the Borough Council, and had been a magistrate for Southampton during the past fifteen or sixteen years. Few men have lived more active lives or sustained more arduous labour; and though possessed of singular vehemence of temperament, there was a softer side to his nature, which often found expression in acts of kindness and consideration unknown to the outside world.

THOMAS HOPGOOD, M.R.C.S.

MR. HOPGOOD (whose death was announced in our issue of Oct. 23rd) was the last of the old practitioners of Chipping Norton, Oxfordshire. He had been in practice in that town since his qualification in 1846. For some time past the deceased gentleman had been in failing health, never having recovered a severe illness he had two and a half years ago, when he was suddenly seized with severe rigors and became unconscious after exposure for several hours in the cold upon business connected with the office of mayor. During the past winter he was confined to his bed for some time from an attack of bronchitis. From this, however, he so far recovered as to be able to resume his professional duties. A few weeks since he became seriously indisposed, and died on the 8th ult. He was not one of the old school who cared little about the progress of medicine and surgery, but his greatest interest was in hygiene, and he lived, as he said, to see the greatest improvement that had ever taken place in the town—the supply of good water, and with it the almost total disappearance of fever. Mr. Hopgood had for a lengthened period taken an active part in the municipal affairs of the town. He was elected a member of the Council in the year 1862, and on the death of Mr. Alderman Rawlinson was promoted to an aldermanic chair, which he occupied up to the time of his death. Mr. Hopgood had also three times filled the office of chief magistrate of the borough—viz., in 1863, 1873, and 1877. He leaves three sons, all of whom are in the profession. Mr. Hopgood during his last severe illness was attended by Dr. Hutchinison, of Chipping Norton.

A MEETING, over which Sir Joseph Fayrer presided, was held on Monday in the Langham Hotel, at which it was determined to form a Sanitary Assurance Association "for the purpose of securing to its members, at a minimum cost, those advantages which the progress of sanitary science has made available." It was agreed that Professor de Chaumont, F.R.S., Professor Hayter Lewis, F.R.I.B.A., Mr. H. Rutherford, Professor Corfield, M.D., Mr. George Aitche-son, and Mr. Mark H. Judge be appointed a provisional committee, with Professor Corfield as chief sanitary officer, and Mr. Judge as surveyor *pro tem.*, and that they be requested to organise the association on the basis of a prospectus which was circulated, and report to a future meeting.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on Oct. 28th:—

Davy, Henry, M.B. Lond., Lancaster House, Savoy-street.
Heron, George Allen, M.D. Glas., Margaret-street.
Mann, John Dixon, M.D. St. And., Manchester.
Smith, Robert, M.D. Aberd., Charing-cross Hospital.

On the same day the following gentlemen were admitted Licentiates of the College:—

Bulteel, Marcus Henry, Stonehouse, Plymouth.
Corbould, Henry Francis, Thornton-heath.
Cotterell, Edward, University Hospital.
Henry, Joseph, Camden-square.
Hubbard, Henry William, Ford-park, Plymouth.
Jennings, Edward, George-street, Manchester-square.
Sisley, Richard, Park-row.
Smith, George Munro, Clifton.
Swale, Harold, Leicester-place.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 28th:—

Marlow, Frank William, Wantage, Berks.
Powell, Simpson, Upper Woburn-place.
Whiting, John, Kingsfields, Beccles.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Charles Frederick Burton, Queen's College, Birmingham; Robert Cheyne, King's College; Samuel Wyborn, Charing-cross Hospital.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW AND ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH. At the October sittings of the Examiners at Glasgow the following gentleman passed the First Examination:—

Conway, Thomas A., Glasgow.

The following gentlemen passed the Second Examination, and were admitted Licentiates of the two bodies:—

Darwin, Geo. A., Manchester.	MacDonald, Charles, Tilsonburg, Canada.
Dickson, Peter S., Edinburgh.	M'Kechnie, Neil, M.B. Ontario.
Ferguson, John, M.B. Toronto.	Rawes, Geo. B., Liverpool.
Hamilton, Oliphant, Glasgow.	Ross, James, Glasgow.
Hannah, Fredk. R., Bombay.	Roberts, Robert, Glasgow.
Jones, A. T. L., Glasgow.	

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the October quarterly examination the following gentlemen passed the First Examination:—

Clark, M., Glasgow.	Jardine, Peter F., Glasgow.
Crowther, G. D., Luddenden.	McKee, Thomas, Glasgow.
Dickson, F. H., Glasgow.	Owen, John W., Glasgow.
Hitchen, Thos. C., Birmingham.	Parke, John L., Manchester.

The following gentlemen passed the Second Examination, and were admitted Licentiates:—

Bhabha, S. D., Glasgow.	Jean-Louis, N., Mauritius.
Deene, Ed., Wincanton.	Lo Page, John F., Durham.
Forsyth, David, Glasgow.	Mackintosh, A., Scarborough.
Gilroy, James, Paisley.	Wigmore, James, M.D., Tiverton.
Govan, Joseph, Limerick.	

It is proposed to purchase additional land in view of the extension of the South Yorkshire Pauper Lunatic Asylum.

JOHN WILLIAM BUSTEED, L.R.C.S.I., and John Ireland Donovan, M.D., have been placed on the Commission of the Peace, the former for the county of Kerry; the latter for the county of Cork.

IN connexion with the St. John Ambulance Association, an advanced course for certificated females is being conducted at the Royal Hospital for Children and Women, Waterloo-road, where, after each lecture, the students are taken round a ward and given practical hints on nursing and the treatment of the sick.

THE 21st annual Hospital Sunday collection in aid of the local medical charities was made in the various churches and chapels of Birmingham on the 31st ult., the proceeds being devoted this year to the General Hospital. The receipts in most cases showed a slight falling off as compared with those of the two previous years.

We have received from Messrs. Eade & Caulfield, of Princes-street, Cavendish-square, a copy of a photographic group of the members of the medical and surgical staff of St. Bartholomew's Hospital. The picture contains forty-four portraits, from life, artistically arranged, enclosed in a neat frame of black and gold. The cost is one guinea.

UNIVERSITY OF DURHAM.—Examinations for (1) the practitioner's degree of M.D., (2) the degree of M.D., (3) the degree of M.B., (4) the degree of M.S., will commence on Monday, Dec. 6th, 1880. The examinations are held at Newcastle-upon-Tyne. The names of candidates should be forwarded to the Registrar, Dr. Luke Armstrong, 26, Clayton-street West, Newcastle-upon-Tyne, on or before the 8th inst.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. By the will of Mr. W. H. Poynder, late of Harttham Park, the Royal United Hospital, Bath, and the Salisbury Infirmary become entitled to £1000 each, and St. Bartholomew's Hospital to £500. Mr. T. S. Wall, late of Maida Vale, bequeathed £100 each to St. Mary's Hospital, the Western Dispensary, and the Royal Hospital for Incurables. Mr. E. Howard, late of Crowhurst, bequeathed £100 each to the Sussex County Hospital, the Cancer Hospital, Brompton, and the London Hospital. The executors of Miss Caroline Brown, late of Cheltenham, have paid over to the treasurers of the General Infirmary, Leeds, and of the British Medical Benevolent Fund, the sum of £2987 16s. 11d. each, being their respective shares of the testator's residuary personal estate.

ASSOCIATION OF REGISTRARS OF THE METROPOLITAN HOSPITALS.—At a meeting held at King's College Hospital on Nov. 3rd (Dr. Mahomed in the chair), the following officers were elected:—Dr. Mahomed (Guy's), President and Chairman of Medical Section; Mr. Harrison Cripps (St. Bartholomew's), Vice-President and Chairman of Surgical Section; Dr. Dunbar (St. George's), General Secretary, and Secretary of Medical Section; Mr. Boyd (University), Secretary of Surgical Section. The following resolutions were carried *nem. con.*:—1. That the Association will draw up a form of index of medical and surgical cases available for the use of each hospital. 2. That it will, if possible, compile on the same model a combined index of cases admitted into the metropolitan hospitals during the year. 3. That one of the objects of the Association be to co-operate for the investigation of questions of obscurity. 4. That the secretaries of the medical and surgical sub-committees shall summon a meeting for Wednesday, Nov. 17th, at 8 P.M. at King's College Hospital, for the purpose of drawing up a form of index of medical and surgical diseases.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

AINLEY, D., L.R.C.P.Ed., M.R.C.S.E., has been reappointed Medical Officer of Health for the Borough of Halifax. £100 per annum.
BARRY, E. J., M.D., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Hollinbourn Union.
BODKIN, P. J. T., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Attendant to the Royal Irish Constabulary, Tuam.
BURKE, J. M., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Carney-street No. 2 Dispensary District of the Sligo Union, vice O'Neill, resigned.
CHARLTON, A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Fifth District of the East Ashford Union.
DALSTON, G. W., M.R.C.S.E., has been appointed Medical Officer for the Brough District of the East Ward Union.
DALY, J. C., L.R.C.P.Ed., L.R.C.S.E., has been appointed Medical Officer to the Borrisokane Dispensary of the Borrisokane Union.
EWBANK, F., L.R.C.P., M.R.C.S.E., has been appointed Resident Surgeon to the Cheltenham General Hospital and Dispensary, vice Taylor, resigned.
FIRTH, E., M.B., C.M., has been appointed Medical Officer to the Debenham District of the Bosmere and Claydon Union, vice W. W. Cuthbert, resigned.
FRAZER, W., B.A., M.D., has been appointed a Medical Officer to the Boscombe Infirmary, Bournemouth.
GARDEN, R. J., M.D., C.M., has been appointed Surgeon to the Aberdeen Royal Infirmary.
HANRAHAN, J. A., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Hollymount Dispensary District of the Ballinrobe Union, vice Hawkins, resigned.
HEDLEY, E. A., M.R.C.S.E., has been appointed Medical Officer to the Felton District of the Alnwick Union.
HEMMING, W. D., F.R.C.S.Ed., has been appointed a Medical Officer to the Boscombe Infirmary, Bournemouth.
KEER, G. E., L.R.C.P., has been appointed Medical Officer to the Seventh District of the Woodbridge Union, vice Hughes, deceased.

LOUGH, J. J., M.B., has been appointed Medical Officer to the N. Postal District (Islington Division), vice Harston, resigned.
NEVE, A., L.R.C.S.Ed., L.R.C.P.Ed., has been appointed Resident Surgeon to the Livingstone Memorial Medical Mission Dispensary, Edinburgh.
PIRRIE, W., M.D., F.R.S.Ed., has been appointed Consulting Surgeon to the Aberdeen Royal Infirmary.
SYMONS, G. F., M.R.C.S.E., has been appointed Resident Medical Officer to the Brixton Dispensary, Water-lane.
TAYLOR, R. S., M.B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Breadalsh District of the Sharrowd Union.
TURNER, J. E., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Attendant to the Royal Irish Constabulary, Tuam, vice T. B. Turner, deceased.
WANOSTROCHT, V., M.B., C.M., has been appointed Medical Officer for the Seventh District of the York Union.
WHITE, J., F.R.C.S.E., has been appointed Consulting Surgeon to the Nottingham General Hospital, on retiring, after twenty-one years, from the office of Surgeon.
WILKINSON, Mr. O., has been reappointed Public Analyst for the Borough of Stockport for one year.
WILSON, W. J., L.R.C.P.Ed., M.R.C.S.E., L.F.P.S.G., has been appointed Medical Referee to the Midland Counties Permanent Relief Fund.

Births, Marriages, and Deaths.

BIRTHS.

BOWEN.—On the 23rd ult., at Kirkley, South Lowestoft, the wife of Edward Bowen, M.R.C.S.E., of a daughter.
BOYS.—On the 25th ult., at Pill, Bristol, the wife of A. H. Boys, M.B., of a son.
CREED.—On the 30th ult., at Rathkeale House, Girdler's-road, West Kensington-park, the wife of C. P. Creed, M.R.C.S.E., of a son (still-born).
KESTEVEN.—On the 31st ult., at Holloway-road, N., the wife of W. Henry Kesteven, M.R.C.S.E., of a daughter.
MORGAN.—On the 4th ult., at Mussooree, India, the wife of Surgeon-Major Jerome Morgan (prematurely), of a daughter, who survived her birth but a short time.
SCOVIL.—On the 27th ult., at Hove, Brighton, the wife of Francis S. Scovil, M.R.C.S.E., of a daughter.
SHEPHERD.—On the 4th Sept., the wife of Charles Carter Shepherd, B.M., of the General Hospital, W.I., of a son.

MARRIAGES.

BROWNE-SIMPSON.—On the 16th ult., at St. George's Church, Stonehouse, Samuel Browne, M.D., son of Dr. Browne, J.P., Belfast, to Ada Eliza, daughter of the late George Simpson, Surgeon, of Gower-street, London.
DE POURTALES-MARCEY.—On the 28th ult., at Genthod Parish Church, Geneva, Count Hermann de Pourtales, of the Royal Prussian Cuirassier Guards, to Marguerite (Daisy), only daughter of W. Marcey, M.D., F.R.S., of Grosvenor-street, and Yvoire, Lake of Geneva.
HOGG-JENKYN.—On the 30th ult., at St. Mary's, Ealing, Arthur John Hogg, M.R.C.S.E., of Netley Villas, Ealing, to Ellen Eugenie, eldest daughter of Osborn Jenkyn, Esq., of Woodside, Ealing-common.
LEWIS-WILSON.—On the 26th ult., at the Parish Church, Kingston-on-Thames, John Lewis, Surgeon, Queen's Own Corps of Guides, Murdan, Punjab, to Annie Chambers, second daughter of the late H. T. Wilson, Esq., of Liverpool.
LOWNDES-LEWIS.—On the 26th ult., at St. Nicholas Parish Church, Liverpool, Frederick Walter Lowndes, M.R.C.S.E., of Liverpool, to Elizabeth Ellen, youngest daughter of the late John Lewis, of Helsby, Cheshire.
MUMBY-ROSS.—On the 2nd inst., at Milton, Portsmouth, by the Rev. P. H. Good, M.A. (uncle of the bridegroom), Bonner Harris Mumby, M.B., to Nellie, only daughter of Alexander Ross, of Southsea.

DEATHS.

BEALE.—On the 25th ult., at Royal-crescent, Cheltenham, Anthony Beale, Esq., late Surgeon-Major, Bengal Army.
COOPER.—On the 31st ult., at his residence, Croydon, George Cooper, M.R.C.S.E., in his 70th year.
GOODEVE.—On the 27th ult., at Drinagh, Stoke Bishop, near Bristol, Edward Goodeve, M.B., Deputy Inspector-General of Hospitals (Bengal), and Honorary Physician to the Queen, aged 64.
MOORE.—On the 30th ult., at Hastings, George Moore, M.D., M.R.C.P., aged 77.
PAINTER.—On the 31st ult., at Beaufort-gardens, S.W., Richard Budd Painter, M.D., F.R.C.S., aged 54.
STRATON.—On the 17th ult., Alexander Straton, M.D., of Steeple Langford, aged 64.
WHITEFOORD.—On the 28th ult., at Albany-street, Caleb C. Whiteford, M.R.C.S.E., aged 35.
WILKINSON.—On the 25th ult., T. J. Wilkinson, M.R.C.S.E., late of Manchester.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS ETC. RECEIVED.

BAILLIÈRE, TINDALL, & COX, London.

An Elementary Treatise on the Function of Vision and its Anomalies. By Dr. Giraud-Teulon. Translated from the Second French Edition by Lloyd Owen, F.R.C.S.I. pp. 158.

BATSFORD, B. T.

The Plumber and Sanitary Houses. By S. Stevens Hellyer. Second Edition. pp. 321. With Engravings.

BLACK, A. & C.

An Introduction to the Study of Fishes. By A. C. L. G. Günther, M.A., M.D., &c. pp. 720. With Illustrations.

Nunn. (Evans, Baltimore.)—Fraser's Magazine, November.

INTERNATIONAL MEDICAL CONGRESS.

A MEETING of the Executive Committee took place at the College of Physicians on Tuesday, the 19th of October, Dr. J. Risdon Bennett in the chair. The Secretary-General, Mr. MacCormac, presented a statement of the work which had been done since the last meeting of the Committee on August 3rd. A circular announcing the meeting of the Congress in London next year, together with a list of the proposed officers of the various sections, and a provisional list of subscriptions, have been sent to every medical man whose name stands on the Register. In addition to these circulars in English, circulars in French have been widely distributed in France, Holland, Belgium, Norway, Sweden, Denmark, Switzerland, Portugal, and Russia. Circulars in German have been sent to the principal medical men throughout Germany and Austro-Hungary. Circulars in Italian have been sent out in Italy; and circulars in Spanish in Spain. A special circular in English has been sent to the leading medical men in the Northern and Southern States of America; and, in addition to all these, a number of circulars have been sent to medical men residing in various other parts of the world. Lastly, a copy of one of the circulars and of the proposed list of officers has been sent to a number of the home and foreign medical journals, and in several of these cordial and appreciative notices have already appeared concerning the intended Congress. Among others, the following medical men have already announced their intention to attend:—Professor Langenbeck, Berlin; Professor Billroth, Wien; Professor Volkman, Halle; Professor König, Göttingen; Professor Frendelenburg, Rostock; Professor Busch, Bonn; Professor Reyher, St. Petersburg; Professor Charcot, Paris; Baron Larrey, Paris; Professor Morache, Bordeaux; Dr. L. Labbé, Paris; Professor Theod. Schwann; Professor v. Recklinghausen, Strassburg; Professor Spiegelburg, Breslau; Dr. Benedikt, Wien; Professor Brandes, Aachen; Dr. Bämler, Freiburg; Dr. Munnich, Berlin; Dr. Fokker, Groningen; Dr. Bidder, Mannheim; Dr. Mikulicz, Wien; Dr. J. Peczeley, Buda-Pesth; Dr. Waldeyer, Strassburg; Dr. Königsfeld, Aachen; Dr. Götz, Strassburg; Dr. Sandre, Oran; Dr. L. Martineau, Paris; Dr. A. Herbert, Paris; Dr. L. Jullien, Paris; Dr. Brachet, Aix-le-Bains; Dr. Lahuppe, Dr. Chervin, Dr. Demons, Bordeaux; Dr. Barr, Geneva; Dr. Joel, Lausanne; Dr. C. Romano, Naples; Dr. S. Giordano, Cannerio; Professor Albanese, Palermo; Professor Argentio, Palermo; Dr. Keyes, New York; Dr. W. Y. Yandell, Louisville, Kentucky; &c.

Meetings of the officers of the various sections have been held, and in several of them a provisional list of subjects for papers and discussion has been drawn up, printed in the three official languages, and widely distributed at home and abroad. The following are the provisional lists prepared in Sections of Surgery, Diseases of Children, Diseases of the Ear. We have already published the list of subjects in State Medicine (see p. 679):—

SECTION V.—SURGERY.

1. Recent Advances in Abdominal Surgery. 2. On the Surgical Treatment of certain Diseased Conditions of the Kidney. 3. On recent Advances in the Method of Extracting Stone from the Bladder. 4. On the Treatment of Operation Wounds. 5. On the Treatment of Aneurism by the Elastic Bandage. 6. On the Comparative Advantages of Early and Late Resection in Diseases of Joints.

JOHN ERIC ERICHSEN, Esq., P.R.C.S., F.R.S., President.

PROF. E. H. BENNETT, M.D.,
PROF. HUMPHRY, M.D., F.R.S., } Vice-Presidents.
W. S. SAVORY, Esq., F.R.S.,
H. G. HOWSE, Esq., M.S., } Secretaries.
THOMAS SMITH, Esq.,

All communications regarding Section V. should be addressed to H. G. Howse, Esq., M.S., 10, St. Thomas's-street, London, S.E.

SECTION VII.—DISEASES OF CHILDREN.

MEDICAL.—1. The real Position of the so-called Rubella, Rötheln or German Measles, and its relation to Scarlatina and Measles. 2. Syphilis as a Cause of Rickets. 3. On the different kinds of Spinal Paralysis and Myelitis in Children. 4. The Conditions governing the occurrence of Albuminuria and of Paralysis as attendant on Diphtheria, or as Sequelæ. 5. The relationship of Chorea to Rheumatism, with especial reference to the nature of the Heart Murmur which so frequently attends Chorea. 6. The forms of Acute Tuberculosis other than ordinary Tubercular Meningitis.

SURGICAL.—1. The Surgical Treatment of Croup and Diphtheria. 2. The Surgical Aspect of Tapping for Empyema. 3. The Pathology and Treatment of Genu Valgum. 4. The Treatment of Diseases of the Joints, especially with a view to the Prevention of Deformity. 5. Treatment of Spinal Curvature, with special reference to Sayre's method. 6. The Nature of the so-called Surgical Scarlet Fever.

CHARLES WEST, President.

SAMUEL GEE,
TIMOTHY HOLMES, } Vice-Presidents.
HORATIO DONKIN,
ROBERT W. PARKER, } Secretaries.

All communications regarding Section VII. should be addressed to Dr. H. Donkin, 60, Upper Berkeley-street, London, W.

SECTION X.—OTOLOGY.

1. On the Value of Operations in which the Tympanic Membrane is Incised. 2. On Morbid Growths within the Ear and their Treatment. 3. On Loss of Hearing where the External and Middle Ears are Healthy.

WILLIAM B. DALBY, Esq., President.
DR. CASSELLS,
DR. FITZGERALD, } Vice-Presidents.

All communications regarding Section X. should be addressed to W. Laidlaw Purves, 9, Stratford-place, Oxford-street, London, W.; or Urban Pritchard, 3, George-street, Hanover-square, London, W., Secretaries.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

A PARADISE OF RHUBARB.

M. PRJCVASKY, the Russian explorer, in a recent letter giving an account of his movements on the Chinese frontier, in Eastern Turkistan, describes a veritable paradise of rhubarb. Here he chanced upon a locality where the plant was found in prodigious quantity, and in the older plants with roots of colossal proportions. Taking at hazard one of these roots, he found that it measured 16 inches in length, 12 inches in breadth, 7 inches in thickness, and weighed 26 pounds.

Mr. W. Roger Williams.—The paper is marked for insertion.

WATERING-PLACES AND THEIR SANITARY CONDITION.

To the Editor of THE LANCET.

SIR,—The public owe you many thanks for your article on the Sanitary State of Margate. My own experience of that town enables me to corroborate your statements. The condition, however, of other watering-places, where men do congregate in large numbers, is equally bad, and equally deserves the lash of your vigorous whip. I give you in a few words my experience of Great Yarmouth, where it is stated that more than 20,000 visitors were enjoying the breezes of the eastern coast during the month of August.

As at Margate, so at Yarmouth, there is no system of drainage. Cess-pools exist throughout the town in the back yards of the dwelling-houses. I went to Yarmouth with a delicate and ailing wife and two children in the month of August, when the weather was at its hottest, being ordered thither by my doctor for my wife's restoration to health. A few nights after our arrival I woke suddenly, and found my bedroom filled with the most abominable stench with which my olfactory nerves were ever afflicted. To jump up, close the open window—through which the horrid stench was pouring,—and to burn some brown paper was the work of a minute. In answer to my inquiries the next morning, I found that a cesspool, immediately under my bedroom window, had been emptied during the night, and that the landlady had cautioned her servants to close their own windows, but, dreading the hasty exodus of her lodgers, had expressly ordered them not to communicate the impending night-work to us. One of my boys was seized in a few days with shivering fits and feverish symptoms, which only vigorous measures prevented, I believe, from taking the form of serious illness. The other lad had an abscess in the ear, and was otherwise unwell. I had sickness and all-overish feelings, which necessitated, as in the case of the others, application to a neighbouring medical man. This was going to the seaside for health! The glorious breezes of Great Yarmouth are undeniable, and thankfully do I acknowledge their potency; but it seems the height of infatuation for man to stop the flow of healing influence by an obstinate disregard of the decencies and purities of modern civilisation.

I am, Sir, yours obediently,

H. W. G.

London, Oct. 20th, 1880.

TABES DORSALIS CURED BY NERVE-STRETCHING.

DR. LANGENBECK reports in the *Berlin. Wochenschrift* a case of tabes dorsalis, in which nerve-stretching, conducted under antiseptic precautions, resulted in a complete cure. The left sciatic was first operated upon; the motor and sensory paralysis following disappeared in a few days. Twelve days subsequently the right sciatic and both crural nerves were stretched, and with the same results. The feebleness which marked the first efforts at locomotion soon passed off, and the ataxic symptoms disappeared.

L.S.A.—It would scarcely be worth while to raise the point.

Dr. Mahomed.—Too late for this week.

PAYMENT OF MEDICAL OFFICERS OF HOSPITALS.

To the Editor of THE LANCET.

SIR,—So many of the letters and articles contained in your late numbers point in the same direction that it appears right to call attention to their common end. Some of your correspondents condemn, and others defend, cheap dispensaries; while Mr. Ayres, of Deptford, casually mentions that in his ordinary practice he charges poor people as low as 6d. and 1s. a bottle for medicine; and at Guy's Hospital the authorities are disputing the authority and position of doctors who give time and hard work to the public free of all charge.

Surely now is the time to consider and discuss how it is that medical men so seldom make a retiring competence for themselves and a provision for their families. How is it that they as a profession always occupy an ambiguous position in "good society," only patronised or sneeringly tolerated when other professional men take an undisputed position? "Fine words butter no parsnips," and yet we are content to accept a few words of compliment about the unselfishness of our noble profession (often spoken with a half-veiled contempt), in place of the practical and pecuniary results of work that should stand on its own merits. People are judged much by the value they put on themselves and on their work. The public will only give us even the honour of its esteem when it is sure that no practical benefit will follow to us. The best man among us has never yet been made a peer, while more than half the peerage is made up of descendants of lawyers, who knew better than to work half their time for nothing. It is high time to recognise this fact, that every man of eminence in the profession who systematically gives gratuitous service in hospital work lowers the status and diminishes the fees of his professional brethren all over the kingdom to the remotest village. No other man or class of men gives systematic labour in hospitals. Why should doctors? Now is the time to speak. Let the profession insist on all its members engaged in hospital work being salaried. The men will be ten times more respected and esteemed at the hospitals; they will raise the position of the whole profession in the public estimation, and the public will delightedly pay us a hundred thousand a year more for services they will value more highly.—Yours truly,

Oct. 22nd, 1880.

MEDICO-ETHICAL.

Club Doctor.—In the absence of a written agreement, it is doubtful whether the claim could be enforced. The matter should be referred to a solicitor.

Dr. W. H. Taylor.—It would, under the circumstances, be contrary to our rule to publish the description.

F.R.C.S. (Calcutta) is thanked for his communication.

THE EAST WIND IN RESPECT TO HEALTH.

To the Editor of THE LANCET.

SIR,—While heat and cold and damp have been constantly referred to as causes of disease, I do not think the effects of a dry wind, such as that from the east in our own country, have been worked out in a precise—i.e., scientific manner. To me its effects are very similar to that of the air of a room heated by a stove, no water being used to moisten the air by evaporation. I have felt the same sensations in a hot climate when doing hard physical work in a hot sun and a hot place, which could be checked only by frequent, though small, drinks of water. At the time I was in excellent condition, and could do any hard work all the day long. After all, one can take such effects of the external air very much as a slow heat-stroke, merely causing irritation, or, carried still further, as in a burn, where still more shock is caused, and the danger consists in the extent of surface injury, not its mere depth. Here the vaso-motor nerves, of course, are the sufferers; then the unpleasant action of this wind, if not well admixed with a southerly one, is the same as that of a burn or heat-stroke, only milder in degree. To show how strong the effects of an east wind are, I may cite its action on that most delicate of scents—viz., that of the hare. On two occasions, when hunting with beagles, the scent was gone in the afternoon, after being good all the morning, we not noticing any change; but in the night, strong easterly winds with frost set in, and the scent felt the influence long before we did. Again, with a pack of the same hounds, an easterly wind blowing, no scent on grass or plough-land; but on a broad beach of shingle an excellent one, simply because the sea-salt kept moisture enough in it to hold the scent. I do not pretend to compare these as identical, but merely to show what effect a dry wind has on animals, and also on the subtle scent given off by some. For the same reasons I believe that erysipelas, incipient sunstroke, relapse of ague, and dysentery are due to the dryness of this wind.

Your obedient servant,

October, 1880.

WILMOT H. T. POWER, M.R.C.S.

THE FORCING SYSTEM IN EDUCATION.

At the thirteenth annual meeting of the Canada Medical Association, a committee was appointed to consider and report upon the subject of excessive brain-work and cramming in schools. This step on the part of the Association was induced by certain facts brought forward by Dr. Grant in a paper read by him "On Gymnastics of the Brain," in which he dealt with the evils resulting to young people of too early education in ill-ventilated and overcrowded school-rooms.

House-Surgeon.—1. No.—2. Yes.—3. For the evidence a fee may be demanded, but not for the post-mortem examination.
Mr. H. W. Hall's letter will appear next week.

DIFFUSION OF ANTISEPTICS AND OTHER REMEDIES IN THE ATMOSPHERE OF APARTMENTS.

To the Editor of THE LANCET.

SIR,—It happens frequently that it is desirable to diffuse antiseptics in sick chambers. Many forms of apparatus to effect this object that have been devised fail for various reasons.

During last spring I had several cases in the treatment of which it was most desirable to have an antiseptic as well as a moist atmosphere. I had in use one of Mr. Swan Nash's bronchitis kettles. This afforded as much steam as could be required; but the small triangular trough with which it is furnished was quite unsuitable for holding any antiseptic. I accordingly removed the first joint of the delivery tube, and fixed in its place a common tin funnel. This was loosely filled with tow; the steam was delivered in greatly increased volume by this alteration of the arrangement. Upon the tow a drachm of pure carbolic acid was sprinkled, and in a very few minutes the odour of the acid pervaded every corner of the apartment. The great advantage of this form of fumigation is—first, its great simplicity; and secondly, the ease with which a supply of antiseptic can be set up. At regular intervals a fresh supply of carbolic acid is sprinkled on the tow, without the smallest difficulty or disarrangement of the apparatus.

It is very remarkable to note how grateful the purification of the atmosphere of a sick room is both to patients and to attendants. Cases of severe pneumonia have been strikingly benefited by the use of carbolic-acid fumigation, and in cases of diphtheria some such arrangement should be continuously in use both for the benefit of the patients and also for the protection of attendants and fellow-occupants of the ward. In a case of great gravity I had an elastic tube fixed to the kettle, and the funnel with the carbolised steam flowing from it was brought close to the bed of the patient, giving wonderful relief to his sufferings. Every sick ward—that is, wards constantly used for sickness—ought to be furnished with the means of antiseptic fumigation, and there are few cases that would not bear the antiseptic steam diffused by this apparatus.

Yours faithfully,

Marlborough College, Oct. 23rd, 1880. WALTER FERGUS, M.D.

Mr. T. P. Stephenson.—The practitioner himself is the best judge. The case is a good one, and the medical attendant should be well paid. Ignoring medicines, 100 guineas, with special charges for London journeys and consultations, would not be too much.

M. M.—The question is a legal one.

INTENTION IN THE DETERMINATION OF SEX.

To the Editor of THE LANCET.

SIR,—With your permission, I should like to ask Dr. Granville how he accounts for difference of sex in the case of twins?—Yours &c.,
October, 1880. A. G. P.

A. M. is referred to an article on the subject in another part of our present impression.

Mr. A. B. Lowndes does not explain the kind of machine for which his device is intended.

"HOMŒOPATHIC PRACTITIONERS."

To the Editor of THE LANCET.

SIR,—In your last issue you accuse the homœopaths of sailing under false colours, as there is no indication of their mode of practice in the Directory. In my own case, and in others that I know of, the fault of this omission is entirely due to the editors of the Directory, who utterly ignored and omitted to insert the announcement of my connexion with the British Homœopathic Society and appointment at the Birmingham Homœopathic Hospital, both of which I returned with their annual circular on two occasions.

I trust to your fairness to make this explanation as public as your accusation; and I must say that it is a little hard upon us that after for several years the head and front of our offending being made the fact of our assuming a distinctive name, we should now be condemned because the distinction is not made in the Directory.

I am, SIR, yours &c.,

ED. M. MADDEN, M.B.,

Surgeon to the Birmingham Homœopathic Hospital.

Birmingham, Nov. 3rd, 1880.

**Mr. Madden, M.B.*, is seeking one object; we are striving for another. He would have the editors of the Medical Directory recognise homœopathic hospitals by inserting appointments to these institutions. This recognition we should deprecate. What we desire is that some distinguishing mark should be placed against the names of homœopaths to avoid mistake.—ED. L.

BRITISH MEDICAL TEMPERANCE ASSOCIATION AT BRISTOL.

UNDER this head *Temperance* writes:—

"I would, with your permission, point out a matter which I think is deserving the attention of teetotalers—that is, the utter untrustworthiness of the statistics set forth to show the advantages of total abstinence over even temperance. I took some rough notes of some of the figures read out by Dr. Ridge in his paper. These figures read thus: There is an Assurance Society which divides its members into non-abstainers and abstainers for comparison as to longevity, with the result that one non-abstainer dies in forty, and one total abstainer in one hundred and forty-one per annum. Again, a Total Abstinence Club, carried on at Colne, has a death-rate per annum of 9.9 per 1000! Well, this means, seeing that people do not often insure their lives until they are twenty years of age—that, in the first case, a person who enjoys some of the good things provided may live to the beggarly age of sixty years on the average; while if he will drink water only, he may live until he is a hundred and sixty years of age! Again, in the second instance, a man after insurance, who is a teetotaler, may live for another hundred years! Such statistics might be brought forward by the genuine teetotal stump orator, and might go down with the unthinking public. But, I would ask, are they worthy of a man having such an eminent position as Dr. Ridge, or a fit pabulum for perhaps his equals?"

Mr. Nourse.—The announcement in our number of October 9th will be found to be correct.

Dr. Jas. Johnstone.—We think it would not be advisable to publish the letter.

SEA-BATHING IN WINTER.

To the Editor of THE LANCET.

SIR,—Having occasionally read remarks in your journal upon cold bathing, I venture to send you some details of my own experience, having bathed in the open sea regularly all the year round for two years and a half, including two severe winters. I am in my forty-third year, of active and temperate habits, accustomed to much exercise in the open air, but not altogether strong, having indeed come to the seaside for rest and change after a partial breakdown of the nervous system, which necessitated an easy life for two or three years. I am careful (1) to stay in the water a very short time: ten seconds in winter and a minute or two in summer is enough for me. I think this is the secret of useful bathing. There is hardly time to lose much heat, and the reaction comes on directly after getting out. (2) Not to bathe if feeling unwell at the time, nor when tired, and to keep the body warm by exercise before and after the bath. I have often missed a single day, twice only three days together, because of a slight cold or biliousness.

As for the benefits, sea-water may be different from fresh; but I agree with your remark that they are questionable, and each must judge for himself. To me personally I think there are general, though perhaps indirect benefits—viz.: (1) *The moral resolution* which has enabled me to go and bathe almost before sunrise (if tide required), with ice and snow to the water's edge, helps one to keep up a good standard of health. (2) *The direct physiological effects* I cannot speak of scientifically; but the act of bathing and the warm and pleasant reaction seem to be almost like an athletic exercise, and certainly in mid-winter I have sometimes felt the exhilarating glow in the most decided manner.

In conclusion, it seems to me that cold bathing requires much care if it is to do good, and I cannot help thinking that many people who go for the seaside in summer and bathe lose most of the benefit by staying in the water much too long.

October, 1880.

I am, Sir, yours truly,

NEMO.

THE USE OF IMPURE MATERIALS IN ERECTING BUILDINGS.

To the Editor of THE LANCET.

SIR,—I have felt interested in the discussion going on in THE LANCET on the above subject, and have been astonished that none of your correspondents have taken notice of the extensive use of putrid matter that is mixed with the plaster in the shape of hair. My attention was drawn to this subject by an outbreak of typhoid fever which raged here some five years ago, and which was almost entirely confined to a district containing a number of newly-built houses—a district, it is true, that was badly supplied with water, but still not to such an extent as altogether to account for the scourge, seeing that the houses which had been inhabited for a length of time were not found to contain the disease to such an extent as those of recent formation. These houses, I may mention, had been occupied before the plaster was thoroughly dry, and it occurred to me that the poison might to a large extent be generated in their walls, and have as its origin the decomposing animal matter with which the lime was mixed. My observations have also led me to notice isolated cases of typhoid occurring in country places, where the houses were in a defective condition as regards their water-tightness, permitting of rain soaking the walls, and no doubt setting up some chemical action between the lime and hair. That the hair which our plasterers use is a source of danger to the occupants of newly-built houses, as also to those whose habitations are damp from defective roofing or drainage, is a fact of which I am thoroughly convinced, and so long as people will be stupid enough to occupy such houses, so long will the evil last; but that a substitute for this putrid animal matter should not have been invented is a disgrace to this enlightened age, and one that will have the serious consideration of our sanitary authorities, is the earnest wish of,

Yours faithfully,

Galashiels, Oct. 26th, 1880.

W. H. MURRAY, M.D.

Mr. Thos. Browne and Inquirer will find on reference to the Directory that Mr. Wm. Arthur Stradling is surgeon in the West Indian Mail Service. H.M.S. was a misprint for R.M.S.

CERTIFICATION OF INSANE PAUPERS.

To the Editor of THE LANCET.

SIR,—Allow me to mention what occurred to me personally on this subject in support of the opinions of your correspondents. Some months ago I was appointed surgeon to a large union workhouse hospital at a fixed salary of £250; no extras. The Local Government Board refused to confirm such an appointment on the ground that lunacy fees cannot be legally contracted for. After a deal of correspondence I agreed to accept £220, with extras, this difference being an average of my predecessor's extras for three years. In a pecuniary point of view I am so far a good deal in pocket.

Yours &c.,

Nov. 1st, 1880.

Address
AT THE

OPENING OF THE ANATOMICAL DEPARTMENT

IN THE

NEW BUILDINGS OF THE UNIVERSITY OF
EDINBURGH.

Delivered October 27th,

By WILLIAM TURNER, M.B., F.R.S.,

PROFESSOR OF ANATOMY.

(Concluded from p. 726.)

AND now, gentlemen, we may perhaps devote a few minutes to the consideration of the question of why it is that the study of anatomy has for centuries, by common consent, been made the foundation of medical education. Anatomy forms the basis of the biological sciences; just as a knowledge of the laws of motion is essential and must be constantly recurrd to at every step, before any true progress can be made in the investigation of the physical sciences, so must the structure of the human and animal frame be appealed to in all attempts at classification, in all inquiries into the adaptation of parts to their uses, in all discussions respecting the functions they perform in a state of health, and the alterations or disturbance in those functions which take place in the course of disease.

As a branch of medical training anatomy may be looked at from two points of view, either in its direct relations to the science and practice of medicine and surgery; or as a valuable educational exercise for disciplining the mind to habits of observation, accuracy and patience, and for strengthening the memory and reasoning powers.

In its direct relations to the science of medicine it is of importance as the science which treats of the structure, position, form, and relations of the constituent parts of the body, and of the construction of the body as a whole; so that in applying yourselves to this subject you are, in short, studying the mode in which the complex mechanism of the human framework is put together. If you are to understand by the term morphology the study of form, internal and external, superficial and deep, then the term anatomy embraces not only morphology but something more. For superadded to the conception of form, position, and relations you have that also of structure and construction. Hence by its study you are enabled to realise the nature of that mechanism which, though you examine it in its dead or passive condition, has yet at one time teemed with life and activity. The study of anatomy is therefore a necessary preliminary to that of physiology, which treats of the functions performed by the organs and tissues of the body when in a state of health; and to that of pathology, which treats not only of disturbed function, but of altered structure. Hence, by the common consent of the schools, anatomy is regarded as a fundamental subject, and forms a part of the early training of every student of medicine.

But anatomy has also a direct relation to the practice of medicine and surgery; it is by its study that you become acquainted with the position and relations of all those tissues, organs, and parts, the diseases or modifications in the structure or functions of which, you as prospective practitioners of medicine, have to make yourselves acquainted with. By the careful dissection and manipulation of parts your hand becomes trained to recognise differences in form and structure, and fitted to execute such operative procedures as may be required in the exigences of practice. It is only after you have acquired an accurate conception of normal anatomy and physiology that you can hope to apply your knowledge to the diagnosis of disease, so as to feel certain of the ground on which you stand. Now, as the relations of anatomy and physiology to the practice of medicine and surgery can only be properly realised by the student after he has seen something of that practice, after he has, in short, attended for some time the wards of an infirmary and come face to face with disease, the

No. 2985.

study of these two fundamental sciences should not cease in the early years of a medical curriculum, but ought to overlap, for a time at least, with the hospital work. Hence I am unable to agree with those educationists who would draw a sharp line of demarcation between the study of anatomy and physiology and the final subjects of medical study. The attention of the student ought not, in my judgment, to be withdrawn from the one until he has been introduced to the other by attendance in the wards of a hospital.

I have now told you, gentlemen, what I conceive to be the relations of anatomy to medical science and practice. There are some, however, who fail to recognise this comprehensive aspect of the subject, and who seem to limit it to the study merely of the form, position, and relations of parts, without any reference whatever to their structure and mechanical arrangements; as if the topographical relations of parts and organs embraced the whole science of the subject. But such a limited conception of what is meant by the term anatomy, and what ought to be included in its teaching, is most unphilosophical. It has not been the creed of this University or of the other Universities in Scotland. Here, where the tradition of the character of the teaching of the second Monro still lingers in the schools; here, where John Goodsir, within the recollection of so many of us, propounded the science in its manifold relations,—it would be an act of treason to the memory of these great men, and to the whole history and development of our school, for one moment to entertain it.

Such an erroneous conception, indeed, of the science could never have arisen in a university system of teaching. For by the introduction of the medical sciences into a university curriculum their teaching acquires a breadth and comprehensiveness such as is scarcely attainable in a purely technical school. Their teachers have to regard them not merely with reference to the requirements of a particular profession, but also in their more general bearings. The educational horizon is not, and ought not to be, bounded by the standard of examination exacted either by the University herself, or by other examining boards, but should ever be pushed onwards with the advancing wave of knowledge.

On the other hand, in the purely medical schools, the education has undoubtedly a tendency to become confined within particular limits. There have been, and without doubt will always continue to be, men attached to these institutions actuated by a noble desire to advance the science of medicine, and to inspire similar feelings into the minds of their pupils; and to those who first guided my steps along the thorny paths of professional study I cannot too strongly express my indebtedness. But many of the teachers have as their object not so much to contribute by their own efforts to the progress of medical science, but simply to prepare their pupils for the examination ordeal to which they will have to be subjected. There is thus engendered in the mind both of teacher and pupil the feeling that the examination is the main end or object of education; that the education should be subservient to the examination, and not the means of strengthening the student's mental powers and filling him with knowledge.

Let me give you an illustration of this. A much-valued friend of mine, now occupying one of the most honourable positions open to a member of our profession, told me, not many weeks ago, that when during his studentship he was applying himself one day most industriously to the dissection of the muscles of the back, the demonstrator in charge of the dissecting-room came to him and said, "Why are you wasting your time in dissecting those muscles? They do not examine on them at the Hall." Notwithstanding this remonstrance my friend persevered with his work. He had a higher conception of his educational needs than had his teacher, or he never would have attained his present dignified position.

Such a mode of looking at structure would, I will venture to say, never have presented itself to a teacher in a university. Take these muscles of the back, for example. No one who ever attended the lectures of my distinguished predecessor in this chair can forget the care with which he explained their attachments and arrangement, and showed how they acted in producing the beautiful yet complicated movements of the spinal column. There is, indeed, no part of the human mechanism which presents more features of interest in connexion with the movements of the body than the joints and muscles of the spine. And note what has been the practical result of their careful study. An eminent American surgeon, Dr. Sayre, has founded on it a method

of treatment of curvatures of the spine based on rational and not on empirical principles.

One sometimes reads in introductory and other addresses that anatomy, descriptive and topographical, is a perfect and complete science, and limited in its scope; that all that is or can ever be known about it is recorded in books; that its study, whilst admirable as an exercise for the memory, and as a training for habits of accuracy, exactness, and patient careful observation, is yet of little or no value in forming the mind to reason out the complex facts of biological science, or to strengthen the critical faculty. Such statements are full of fallacy; they show an entire want of appreciation of the real scope of anatomical science, and of its many-sided aspects, and a want of knowledge of the progress which it has made and is still making. I could give you many illustrations of the erroneous nature of such remarks to prove to you that anatomy is an advancing science, and that it exercises, and will for all time continue to exercise, an important influence on the progress of physiology and pathology, and on the practice of both medicine and surgery; but I shall refer to a few only of the advances which have been made since I became a teacher of anatomy twenty-six years ago. And in selecting these, observe that I do not include one of the innumerable additions to our knowledge of structure, both macroscopic and microscopic, but confine myself to the form, position, and relations of parts and organs.

During my studentship the topography of the cerebral convolutions and lobes was very imperfectly known, and the description of their arrangement was meagre and wanting in precision. The publication, however, in 1854 of the important memoir of Gratiolet at once threw a flood of light on the arrangement. Anatomists in this and other countries followed up the subject with much zeal, with the result of placing our knowledge of the surface anatomy of the brain on a definite basis as regards the relations of the convolutions to each other and to the surface of the head.

And note how this series of anatomical researches has borne fruit in advancing our knowledge of the physiology and pathology of the brain. If these preliminary but essential anatomical inquiries had not been conducted we should never have heard of the remarkable experimental investigations of Fritsch, Hitzig, and Ferrier into the functions of the cerebrum. Neither would it have been possible to have localised with precision the seats of morbid processes in the hemispheres, such as enabled Broca to associate right hemiplegia and aphasia with disease of the inferior frontal convolution in the left hemisphere.

The dissections of Dr. Stilling the younger, conducted during the last few months, have proved that the roots of origin of the optic nerves have much more extensive relations than has hitherto been supposed. By tracing a band of these fibres through the pons and medulla to the decussation of the pyramids, he has forced on the attention of physiologists the necessity of reconsidering the functions both of the medulla and the lateral columns of the spinal cord. With every discovery in anatomy, fresh problems are presented to the consideration of the physiologist.

Again, if you compare the descriptions of the cranium written not many years ago with those which have recently been given, you will now find an enormous advance in precision and fulness of statement.

The invention by Cleland, Broca, and other craniologists of new instruments for measuring and delineating the skull and head have enabled anatomists to conduct a series of researches from which we have obtained a much clearer insight into the construction of the skull in individuals, and into the modifications in its shape and in the proportion of its different parts in the different races of men. Questions of the widest interest in their anthropological bearings have in this manner been elucidated.

The careful study of the arrangement and direction of the cranial sutures by Virchow and others has given us a key to the interpretation of the modifications which may be produced in the form of the skull by their premature closure, on the one hand, and by retarded ossification, on the other. So that it would be utterly inexcusable nowadays for an anatomist to commit such an error as was made by a professor of the standing and reputation of Huschke of Jena, just twenty-six years ago, when he figured a cranium deformed through premature closure of the sagittal suture as a normal and typical specimen of the Celtic skull.

In the anatomy of the movable joints, also, great advances have been made, more especially in the acquisition of a more

precise acquaintance with the forms of the articular surfaces. It is a mistake to suppose that the character and direction of the movements of a limb are determined solely by the relative positions of the bones, muscles, and tendons. Undoubtedly these structures play an important part, but they are not the only factors to be considered. The direction and character of the movements of a wheel are influenced by the form of its rim and by the configuration of the surface on which it moves, as well as by the propulsive power applied. And so it is with the joints. The importance of studying the forms of the articular surfaces was indeed insisted on by the brothers Weber in their classical treatise on the Mechanism of the Organs of Locomotion, published in 1836. But great advances have been made during the past twenty-five years in the elucidation of this difficult subject, more especially by the labours of Meyer, Langer, and Goodsir. Should anyone of you wish to investigate a complex biological problem, and to bring into play your analytical and critical powers, you will find full exercise for them in the study of the forms of the articular surfaces of the knee-joint, and in the influence which those forms exert on the character of its movements.

The introduction by the Russian surgeon, Pirogoff, of the method of freezing the human body and then making sections through its different parts—a method which Braune of Leipzig has pursued with so much zeal—has enabled anatomists to obtain much more correct views of the relations of the organs to each other, and to the walls of the regions in which they are situated, than could be done by the ordinary methods of dissection. We have, in consequence, a much more precise knowledge of the real position of the spleen, stomach, heart, uterus, bladder, and other viscera now than was the case ten years ago. Physicians will profit by these additions to anatomical knowledge, and greater definition will be given to their diagnoses. There is indeed no department of practical medicine which has been more a gainer by the introduction of the freezing method than that of obstetrics.

Are we, then, to say that with this year of grace 1880 all further progress in topographical anatomy will cease, that we have reached the limits of our subject, and that henceforth the anatomist must content himself with repeating the observations made by his predecessors, with no hope of himself adding to the progress of knowledge? Such a position would be intolerable if it were true. No man with any intellectual vigour or capacity for thinking and reasoning could be brought to pursue a subject so barren. Anatomy would cease to be a science, and become a mere handicraft. Anatomical teaching would fall into the hands either of the veriest dullards, whose sole object in life would be to earn their daily bread by grinding their pupils up to the level of an examination; or would be pursued for a time by young men desirous of using it as a stepping-stone to practice. The further development of general biological and medical science, so far as they rest on an anatomical basis, would be staved.

But, gentlemen, this picture of the finality of anatomy which has been painted by some writers is a mere fanciful hypothesis evolved out of the minds of those who are so absorbed in the contemplation of their own side of the shield of science, that they do not seem to recognise that it has more sides than one.

In literature and in art no generation treads precisely in the footsteps of its predecessors. The ever-changing social conditions amidst which men live, the development of fresh habits and of ways of looking at objects and actions, the lessons taught by augmented experience, are constantly modifying the character of the environment, and producing variations in our modes of thinking and working.

It is the same, if not even to a greater degree, in science, for each new discovery affords a wider platform from which the world of nature may be surveyed, gives a keener and fuller insight into her complex phenomena, and enables us to obtain a clearer conception of their meaning. In this general advance anatomy participates along with the other medical sciences. Every year adds something to our knowledge of form and structure and of the relations which they bear to function, and a further light is thrown on the mechanism of the human frame.

But there is another fallacy as regards the relations of anatomy to medical education which sometimes finds expression. It has been said that anatomical details, which require from the student so much toil and labour and time to acquire, are but of little use to the busy practitioner, and,

indeed, are for the most part rapidly forgotten as soon as the examination ordeal has been passed. And it is implied that what is so soon forgotten can be of but little use, and the time and toil expended in acquiring things of which the memory retains no grip have been misapplied and wasted. Such a statement, plausible though it may at first sight appear, is really of no moment as an argument against the minute study of the details of anatomy. Let us test its value by a reference to other subjects of study, both general and professional.

Of the shoals of wranglers that Cambridge has sent out during the last quarter of a century, how many, except those who may be following mathematics as a business, have preserved any accurate recollection of the scores of mathematical details which they had at their finger's end at the time of the examination? And yet are we to say that they derived no mental profit from their study? How many of the classmen that Oxford has trained during the same period, always excepting those who are scholars by profession, could now write Latin verses, explain the distinctive characters of the dialects of the Greek language, or even read a Greek play without the aid of a lexicon? and yet have not these men improved in taste, in the power of using their own language, and in literary expression, by the cultivation of the ancient classics?

But does topographical anatomy stand alone amongst the subjects of professional study in that the details are soon forgotten? How long do students retain in their memories the dimensions of epithelium and other cells, the breadth of nerve-fibres, and other finer details of histological study? Who amongst busy practitioners remembers the volume of the different gases, or the atomic weights of any but the most common of the elements? What use in practice is a minute knowledge of the chemical constitution of muscle, or of the experiments relating to the electric phenomena displayed by that important tissue? What is the need to the great bulk of practitioners of being able to discriminate between the characters of the different kinds of chinchona bark or of aloes?

And yet is it to be said that because all these minute details have no direct practical application, and are so soon forgotten, that it is useless ever to learn them, and that the time and labour they have occupied have been wasted? Is not a knowledge of these things, temporary though it may be, evidence of a power of continuous application and of mastering facts. Is it possible, indeed, to obtain a sound general conception of any science, or other subject of study, unless the details are gone into and understood? I could tell you of more than one instance in which men have gone utterly wrong in their enunciation of what they thought were general principles, simply because they had not taken the trouble to master the details. Depend upon it that, whether you learn or do not learn, in the minute details of the more important subjects of study lies the difference between slipshod information and that kind of knowledge the possession of which makes a man feel that he is treading on firm ground and not on the shifting sand.

He who will take time and trouble to follow out the ramifications of a nerve from its origin to its distribution in muscle, or skin, or internal viscus; or he who studies minutely the relations of an artery to the surrounding structures, or of an organ to the walls of the cavities in which it lies, and to the other organs contained in the same, or in an adjacent cavity, will, you may be sure, when he goes to the bedside, bestow an equal care in the examination of the patient whose disease he has to study and to treat. The qualities of mind which have led him to strive for precision of knowledge during his anatomical studies will have been strengthened by his earnest application, and the knowledge of form, position, relations, and structure, which he has thereby attained will find a practical application in his clinical work.

I am well aware that in surgery, for example, owing to the important discoveries of Professor Lister, the methods of practice are not so exclusively anatomical as was at one time the case. But though by his researches additional factors have been brought into use, a knowledge of anatomy is not the less necessary to the surgeon. Because we have new idols to worship, are we therefore to discard the old gods? Nay, is it not the more necessary to be perfect in our mastery of anatomical details? for by the development of the antiseptic system of practice, operations are now possible in regions where at one time no one would have thought of performing them.

If you sufficiently apply yourselves to the observation of the facts of normal relations and structure, the mind will become as it were saturated with these facts, you will be able to form a mental picture of the part or organ, and when the occasion arises to study that part or organ in a state of disease, you will be able vividly to realise the changes which have been produced in it.

Pursue your studies, gentlemen, with an earnest desire to cultivate accuracy and to acquire precision of knowledge. Let your motto be "Thorough." May the words of the preacher be for ever written on the tablets of your memory, "Whatsoever thy hand findeth to do, do it with thy might." And may God prosper the work.

THE TREATMENT OF ASTHMA BY THE INDUCED CURRENT.

By I. BURNEY YEO, M.D., F.R.C.P.,

PHYSICIAN TO KING'S COLLEGE HOSPITAL, AND SENIOR ASSISTANT-PHYSICIAN TO THE BROMPTON HOSPITAL FOR DISEASES OF THE CHEST.

THE recent discussion on Asthma at the meeting of the British Medical Association at Cambridge gives especial interest to the following notes of a case which has lately been brought under my own observation. Two or three days after taking part in this discussion I found myself at the baths of Neuenahr, the guest of that able physician, Dr. Richard Schmitz; and I had an opportunity of seeing and examining with him an aggravated case of asthma, which had been treated by the application of the induced current, and apparently completely cured thereby.

This patient, a gentleman about forty years of age, had suffered from paroxysms of asthma for more than six years, originally induced, he believed, by a severe attack of catarrh. He had tried numerous remedies and visited various climates, but without any considerable relief. This year he was spending a second season at Neuenahr, but without any relief to his asthmatic attacks. Quite recently he was seized with an attack of unusual severity and duration, which had lasted, with but slight intermission, for three whole days and nights, when, as all other resources had failed, it occurred to Dr. Richard Schmitz to try the effect of the induced current applied in the manner suggested by Dr. Max Schaeffer of Bremen.¹ The relief afforded was immediate, and after twelve applications—i.e., an application twice a day for six days—the patient appeared quite well. I examined his chest carefully, and there was no trace of wheezing or of dry or moist râles of any kind. I examined his throat, and found evidence of chronic pharyngitis, the mucous membrane being very granular from the presence of many enlarged swollen follicles; but it was quite clean, and free from mucous secretion. The tonsils were scarcely at all enlarged, although they had been much so formerly. I mention these facts with respect to the condition of the throat, as they bear on the theory of the action of the remedy to which I shall immediately allude. The influence of the remedy had been so complete that the patient's gait and carriage were totally changed, and instead of assuming the bent, stooping figure of the asthmatic, he walked as upright as his fellows.

The galvanic current had been applied to the throat in the situation of the great nerve trunks, the vagus and sympathetic, each pole being applied just below the angle of the jaw and in front of the sterno-cleido mastoideus. The current, mild at first, was gradually increased in intensity until it could be distinctly appreciated by the patient as passing through the soft palate from one side of the throat to the other. It was continued for fifteen minutes at each sitting. It was noticed that the pupils, widely dilated at first, became strongly contracted as soon as the application of the current gave relief. Dr. Max Schaeffer, who has recently advocated this treatment, agrees in the main with Biermer as to the pathology of idiopathic asthma, meaning by *idiopathic* asthma those attacks in the intervals between which no evidence of morbid changes in the lungs can be found. He regards these attacks as a tonic spasm of the middle and

¹ Deutsche Medicinische Wochenschrift, 1879, No. 32.

finer bronchial tubes; but he looks upon the spasm as secondary, and agrees with Weber in believing the primary change to be a swelling or tumefaction of the bronchial mucous membrane, dependent on a fluxionary hyperæmia, itself due to a vaso-motor nervous influence, the principal rôle being played by the pulmonary fibres of the vagus. According to this view asthma is an irritative and reflex pulmonary neurosis. It agrees, in many respects, with the theory of asthma adopted by Dr. Andrew Clark in the discussion to which I have alluded, and which I hold myself as the most consistent with the clinical history and phenomena of the asthmatic paroxysms.

The morbid state, upon which the asthma depends, may— affect (1) the nerve itself, or (2) the coverings of the nerve, or (3) the tissues adjacent to the nerve.

Max Schaeffer lays great emphasis on the third of these conditions—viz., that morbid states of the structures adjacent to the nerve may influence and disturb the nervous currents. Tumours such as nasal polypi, hypertrophied tonsils, swollen cervical or bronchial glands (temporary hyperæmia of these glands), can, according to their position, cause irritative pressure on nerve filaments connected with the respiratory centres. He found that many of his asthmatic patients were the subjects of nasal catarrh, or pharyngeal catarrh, or laryngo-tracheal catarrh. He noticed that swellings of the mucous membranes of these parts were attended with asthmatic paroxysms, and patients would constantly refer the seat of their discomfort lower or higher in the throat, according to the seat of the swelling, and he concludes that all the symptoms of asthma are symptoms of irritation brought on by pressure on nerves which are in connexion with the pulmonary portion of the vagus, and especially in the upper part of the respiratory tract—the pharynx, larynx, and trachea.

He examines carefully the nose and throat, and applies the electrodes according to the seat of the disease. Usually the two electrodes are placed on each side of the neck about two centimetres below the angle of the jaw, and sometimes a little lower down in front of the sterno-cleido-mastoideus. The current must be of good strength, so that the patient can feel the stream go across the larynx and soft palate. In bad cases it should be applied twice a day from fifteen to thirty minutes each sitting. He states that in the most severe cases it has acted "like witchcraft." He has never found the constant current do any good, but he has never failed with the induced current.

Certainly the result of the application of the induced current in the case that came under my own observation was very remarkable.

Hertford-street, Mayfair.

THE ASPIRATOR AS AN AID TO DIAGNOSIS IN CASES OF OBSTRUCTION OF THE BOWEL;

WITH DESCRIPTION OF AN ENTEROTOMY TUBE.¹

By RODERICK MACLAREN, M.D.,
SURGEON TO THE CUMBERLAND INFIRMARY.

I PURPOSE illustrating the use of the aspirator in cases of obstruction of the bowel by giving an account of the instance which drew my attention to its value; and as there are some other points in the case which are worthy of note, I will record its essential features.

Mrs. R—, aged forty-three, wife of a market gardener, was first seen by me on Tuesday, April 20th, 1880. She stated that she had not had her bowels moved since the previous Thursday, though she had taken aperient medicine, and that she had vomited frequently for two days. She was seven months gone in pregnancy. On the following day (April 21st) she miscarried, the child living only a short time. The treatment prescribed consisted in purgatives and frequently repeated enemata, some given with the long O'Beirne's tube. As this failed to give relief, she was next brought under the influence of opium, and subsequently belladonna was given. Each and all seemed to make her worse, and her condition was

best when she was least interfered with. When she had been four days under treatment—this being eight days after the last motion—her state had become urgent; her pulse was very feeble, the vomiting frequent, and the abdomen distended and tense, so that the propriety of operative interference had to be considered. The probabilities were in favour of the obstruction being in the great bowel, for the following reasons: the symptoms were not very acute; the patient always passed plenty of urine; and she stated that for the previous six months she had difficulty with her bowels. This was not due to costive motion, for when she did succeed in getting time to act the consistence was natural. She had occasionally passed blood and mucus. Physical examination, however, gave no help; and it was a matter of extreme doubt in which part of the great bowel the obstruction occurred.

The abdomen on April 23rd was uniformly and intensely distended; it was everywhere resonant, a trifle less so in each loin, and I thought rather less tympanitic in the right than the left, but the difference between either of these regions and the rest of the abdomen was very slight. No hardness or tumour could be felt. No fæcal vomiting occurred. About a pint was the largest enema which could be given, and this usually returned unstained, but occasionally there was slight fæcal colouration. Nothing abnormal could be felt per anum. There was no appearance of cachexia; the patient was a stout florid woman.

It was at this stage that I found the aspirator of essential service. So uncertain were the indications of the seat of stricture that it was a question whether it would not be better to open the small bowel close to the cæcum rather than risk a colotomy, with the possibility of finding the bowel obstructed above the opening. It occurred to me, however, that by inserting an aspirator needle into the loin in the position of the colon I could ascertain whether this contained liquid fæces or not. The patient being placed under chloroform, with the kind assistance of my friend Dr. Murphy I aspirated the colon on the right side, preferring this to the left, because it was slightly less resonant on percussion. The aspirator withdrew air and liquid fæces, giving evidence that the closure of the bowel was below this point. I therefore performed right colotomy. The incision was a deep one, owing to the great amount of abdominal fat; and there was, from the same cause, some difficulty in finding the bowel,—the reverse of what is usually encountered. When the bowel was found, sutured to the skin, and opened, a large amount of flatus and fæces escaped. From the date of the operation the patient did thoroughly well. Five days after the colotomy some liquid fæces passed per anum. On the following day the same occurred, the motion containing much mucus. On the seventh day blood, mucus, and fæces were passed. From this period there was almost always a daily motion per anum, gradually increasing in consistence until she regularly passed a well-formed stool. At the same time liquid fæces escaped freely from the wound. On one occasion, a month after the operation, the bowel prolapsed through the wound. A recurrence of this prolapse was prevented by making her wear an enterotomy tube.

Six weeks after the operation the patient was out of bed. A week later the motions were so natural that I determined to see the effect of plugging the wound before deciding whether or not to let it heal. This was done by closing the tube. I arranged to see her again in a week, during which time she was to wear the plug if she felt no inconvenience from its use. On the morning of the day on which I had promised to see her she was found dead in bed by her daughter, who slept with her.

A post-mortem examination was made in the evening. The heart was found with a considerable covering of fat; the muscular fibre pale, and under the microscope mostly devoid of striation (her pulse had always been feeble and the heart sounds indistinct). Brain, lungs, liver, and kidneys were healthy. The large intestine was distended with air and contained a considerable quantity of solid fæces. The meso-colon was unusually free and large. A couple of inches above the sigmoid flexure was a cancerous mass, measuring an inch in thickness, two inches from above downwards, and occupying most of the circumference of the bowel. A great part of it was undergoing colloid degeneration, and there was some pus in the interior. The opening through the stricture into the lower bowel was a fairly free one. The post-mortem examination was a very instructive one. It was evident why medicinal treatment had failed: purgatives merely forced the contents of the bowel against a closed stricture; sedatives paralysed the bowel and allowed flatus, &c., to accumulate.

¹ Read before the Border Counties Branch of the British Medical Association.

From ulceration or the absence of pressure, or some such cause, the stricture, after the operation, became permeable, and during the last few weeks of her life allowed fæces to pass readily. The free attachment of the great bowel explained how it was that the dulness on percussion, which is usually present above a stricture, could not be detected, the intestine not being in close contact with the abdominal wall.

Obstructions of the bowel are so often obscure that any aid to the diagnosis of their position, or any expedient which will help us in treating them, deserves careful trial. In the aspirator we have an instrument which will determine whether any given portion of the ascending or descending colon contains liquid or not. If it does, it is of necessity above the seat of stricture. The puncture involves no risk. I once saw a post-mortem examination on a case in which the aspirator needle had been pushed into various portions of the bowel within six hours of death, and yet all traces of its use had disappeared. When the presence of liquid fæces in a portion of the colon is ascertained, we know that opening the bowel there will relieve the urgent condition. In the above case the needle was of great service as a guide to the bowel (there is not usually any difficulty in exposing it; but this patient was so fat that the wound was a very deep one, and the intestine was covered by a layer of fat). The class of case in which aspiration is most likely to be useful is: when no stricture or fecal accumulation can be felt per anum; when there is no decided evidence by percussion dulness of a large accumulation in either ascending or descending colon and yet the symptoms point to stoppage of the great bowel, not the small one. I should certainly trust to it to guide me whether to perform colotomy or, on the other hand, to do abdominal section, with the object of removing the obstruction, or opening the lower end of the small bowel.

I have mentioned that I used an enterotomy tube for preventing a prolapse of the bowel. This is a contrivance which I had formerly found of much use in cases of colotomy; it prevents prolapse of the bowel, keeps the opening from closing, and can be made so as to a great extent to prevent contact of fæces with the wound and skin. It consists of a piece of large-sized drainage tubing fastened at right angles to a plate of perforated zinc. The tube is passed into the bowel, the zinc lies on the skin, and is kept there by a band of tape going round the body. The tape is fastened to the zinc plate by india-rubber rings, so as to keep it tense. If it is desired to protect the skin, the tube is passed into the wound through a sheet of gutta-percha tissue. It has a considerable general resemblance to a tracheotomy tube.

Carlisle.

CASCA BARK *VERSUS* DIGITALIS.

By DAVID DRUMMOND, M.A., M.D.,
PHYSICIAN TO THE INFIRMARY, NEWCASTLE-ON-TYNE.

IN the Gulstonian Lectures of 1877 Dr. Lauder Brunton pointed out the close resemblance which existed between the cortex erythrophloei and digitalis in their physiological action. To use Dr. Brunton's words, the action of casca is to strengthen and slow the heart, to contract the arterioles, and increase the urine. For the past two years I have used the tinctura erythrophloei (as it is proposed to style the drug) in a good many cases, a few of which I shall shortly cite with the view of comparing the therapeutical value of the two drugs, especially as regards the certainty and rapidity of their action. The tincture of casca I procured from Messrs. Brady and Martin, of Newcastle, who recommend the dose of five to ten minims, founded on Dr. Lauder Brunton's observations. I believe the strength of the tincture is 1 in 10.

Ellen H— was one of the earliest of my cases in which the drug was tried. Into the details of her malady, or that of the cases to follow, it is unnecessary to enter. Aged eighteen, she had suffered from rheumatism, which left her with a constricted mitral orifice, as evidenced by presystolic murmur, thrill, &c. On the 26th of April, 1879, whilst the heart was beating at the rate of 90 per minute, five-minim doses of the tincture were ordered three times daily. The first evidence of its action occurred in the shape of an attack of epistaxis—i.e., increased arterial tension. On April 30th

the pulse was 88. There being no return of the epistaxis, the dose was increased to eight minims. On May 1st the pulse was 80. On May 2nd ten minims of casca was given, which dose was continued up to the 21st, during which time the pulse remained at about 70. Then it was observed that the patient passed a great deal of urine. The effects of the drug were allowed to pass off, and on June 9th fifteen minims of tincture of digitalis were given thrice daily, the effect of which was to lower the pulse ten beats per minute in about a day. The patient was soon after discharged, the pulse remaining at from ten to fifteen beats below the average until she left.

Alice G—, aged twenty, suffering from mitral insufficiency. Her average pulse was about 100. On April 20th five-drop doses of the tincture were administered, which were gradually increased to fifteen minims three times daily; but owing to an attack of hæmoptysis on April 23rd the casca was stopped, at which time the pulse was at 90. On the 30th, the pulse still remaining about 90 to 95, eight-drop doses of the tincture were given, and continued until May 19th, during which time the pulse scarcely varied at all, but remained about 90, the only noticeable effect of the drug being a diminution in the quantity of urine passed. Dr. Brunton has shown that one of the toxic effects of the drug is to diminish the renal secretion; however, in spite of the small quantity of water passed, the dose was increased to fifteen minims thrice daily; but on the 21st, the flow becoming less, the exhibition of the casca was stopped. The pulse during this time had increased rather than diminished in frequency. It was found that it was only necessary to omit the casca for two days to allow the flow of urine to become normal again. On May 24th fifteen drops were again given three times in the day, and continued till the 31st; but the drug appeared to have lost its effect, for on that day the pulse was at 120 per minute. The tincture of digitalis was substituted, in ten-drop doses. On June 4th the pulse was down to 100, when the digitalis was increased to fifteen drops. On the 9th the pulse was at 50; in consequence the digitalis was stopped, and in a few days the pulse again became rapid—i.e., 100; but now the digitalis had lost its influence, for fifteen- and twenty-drop doses thrice daily failed to bring down the number of beats.

In the next case the drug was pushed much more energetically.

Wm. W—, aged fifty-four, presented unmistakable symptoms of mitral stenosis. Although there was no murmur, yet the rapid, irregular heart, the cyanosed face, the congested lungs, with hæmoptysis and dyspnoea, told a tale of obstruction on the left side of the heart. On the 14th of July, 1879, the heart—counted with the stethoscope, as many of the beats did not reach the wrist—was at 160 per minute, irregular and intermittent. Ten-drop doses of the tincture of casca were given three times a day. On the 17th, the pulse was much steadier, and reduced to 100. All the beats seemingly reached the radial. The quantity of water passed was much increased. The administration of the drug was continued, and larger doses employed, the increase being gradual. On Aug. 1st, thirty drops three times a day were given, and in a few days the dose was increased to thirty-five drops. On the 11th, a week after the maximum dose named had been employed, the pulse was at 110, and very irregular. The drug was then discontinued, the urine being diminished in quantity. On Aug. 16th—no medicine was given in the interval—the heart was beating at the rate of 152 in the minute, 120 of which only reached the radial. Digitalis was then exhibited—twenty drops of the tincture three times a day—the immediate effect of which was to steady the cardiac pulsations, and to render them both slower and more regular; for, on the 18th of the same month, the heart beats were 120, all of which reached the wrist. The digitalis was continued until Sept. 16th, 1879, on which day the patient left the hospital, his pulse much more regular, and at 80 in the minute.

This patient came again under treatment in the hospital on May 25th of the present year, at which time his pulse was at 150, and very irregular. He was ordered ten-drop doses of the casca administered as before, which was increased on June 4th to twenty drops, the pulse remaining unaltered. On the 12th the pulse was steadier, and reduced to 120 in the minute. Then camphor-water was substituted and continued for eight days, during which period the pulse rose again to about 150, and became more irregular, being with difficulty counted. On June 20th the camphor-water was discontinued, and in place twenty-drop doses of the

tincture of digitalis were employed—a larger quantity invariably caused vomiting. On the 28th the pulse was again reduced to 120, but a continuance of the remedy failed to bring about a further reduction.

I have used the drug in several other cases besides those briefly recorded above, but as the trials simply served to strengthen my previously formed impression as regards the therapeutical value of the tincture of casca, no object can be gained by citing them. To sum up my limited experience of the remedy:—It is undoubtedly a very useful addition to our somewhat restricted list of therapeutic agents in the treatment of cardiac cases, serving, like digitalis, to lower the pulse-rate, and, whilst increasing the force of the systole, to render the heart more regular. In comparing the two drugs, whilst recognising the value of casca, I think digitalis is the more reliable remedy of the two; it seems to act more rapidly and with more certainty. It may, however, yet be found that the cases in which each drug is to be employed must be selected; some cases requiring perhaps stimulation of the cardio-inhibitory centre in the medulla—casca,—whilst others may be best suited by a remedy which acts on the peripheral inhibitory apparatus in the heart—digitalis.

In my cases it did not appear that the remedy was cumulative, for in the case of Alice G—the quantity of urine, which had been very much diminished by the drug, became normal a day or two after its discontinuance. The drug appeared to me to act in the desired manner upon the heart only so long as the quantity of urine was increased.

Sphygmographic tracings in the cases given showed well the high arterial tension as the result of the drug; this was especially noticeable in the first and third of the cases. In Alice G—'s case the tracing, taken whilst the drug was being administered, but without effect, the pulse being increased in rate, showed a low-tension pulse. In a case of thoracic aneurism in which the drug was tried, the effect was an increase in the pain, the result of increased arterial tension.

Newcastle-upon-Tyne.

FIVE YEARS' SURGICAL WORK IN THE CARDIFF INFIRMARY.

By ALFRED SHEEN, M.D.,
SURGEON TO THE INFIRMARY.

(Continued from p. 691.)

OPERATIONS for the removal of cancerous growths do not leave a very favourable impression on one's mind. Whatever their immediate results may be, and in some cases I believe these results to be highly beneficial in a variety of ways, the disease, as a rule, either returns at the seat of operation or in some other part, and the patient eventually succumbs to it. One or two cases may be deemed worthy of a more extended record.

S. P—, aged forty-four (Nos. 36 and 37) was admitted in December, 1877, with an enormous sarcomatous tumour in the posterior aspect of the right thigh, extending from the top of the femur nearly to the popliteal space. It was removed under antiseptic precautions. The temperature varied from 99° to 101° for eleven days, after which it became and remained normal. She was again admitted in February, 1879, when another tumour, the size of a small orange, was removed antiseptically, from the upper part of the thigh, and the pulse and temperature were normal throughout. Again, during this year, I have dissected out three nodules, each the size of a small hen's egg.

In the case of T. B— (No. 41) I had previously twice operated for epithelioma of the lip, after which there was no return of the disease at its original seat, but glandular enlargement supervened at the angle of the jaw, and, unfortunately, he did not seek advice (although cautioned to do so) until it had attained such a size as to render his chances of benefit from further operative interference exceedingly problematical. He was, however, very anxious to have something done, and I removed it partly by the knife and partly by tearing with my fingers. There was considerable venous hæmorrhage. After its removal a large gap was left showing the digastric muscle, the hypoglossal nerve and

other structures as they would appear after an elaborate and careful dissection.¹ The man after his discharge had a severe attack of erysipelas of the face, from which he recovered, but he died twelve months after the operation of an extension of the disease.²

Of the cases of epithelioma of the penis one was removed by the galvanic cautery, but I was so unfavourably impressed with it that I did not use it again. A clean cut with a knife is far preferable to the eschar produced by the cautery and its subsequent tedious separation.

Of the eye cases, two cases of senile cataract were dealt with successfully by the flap operation, whilst a third, treated by iridectomy and the modified linear incision, was a failure from escape of vitreous and intraocular hæmorrhage. Abcission of the cornea, for a very prominent staphyloma, left a not unsightly stump, upon which a glass eye may at some future time be fixed.

During the removal of a scirrhus of the breast in a woman aged sixty-four, the patient twice became pulseless, but recovered on tilting her up, head downwards.

In the case of popliteal aneurism the femoral was tied in the usual situation with carbolised catgut, and the wound closed with styptic. No chloroform was given.³

	3	13	8	1	25

In this division there were eighteen males and seven females; no deaths. In these cases, where operations have been performed, Esmarch's bandage has always been used, and with great advantage, making the operation as plain as though it had been performed on the dead body. The chisel and hammer have also been resorted to in place of the usual bone instruments, in cutting through new bone and in dividing large pieces of necrosed bone, and in some cases I greatly prefer this method of proceeding. Lint steeped in carbolised oil (1 to 10), stuffed into the wound, has been the usual mode of dressing for some days, and in some cases I have used terebene in place of the carbolised oil with advantage. It has answered as well, or better, and certainly has a more agreeable odour. I think we may be, at times, too hasty in interfering with diseased bone, especially in the hand and foot, for I have cases under my observation which go to prove that, by patience, the use of the stiff bandage and long-continued expectant treatment we may sometimes fairly assume that such cases will recover without operative interference. I had one such case in 1878 of disease of the bones of the foot, and that patient, under the treatment I have here indicated, is now nearly well.

JOINT.

The cases of joint diseases were equally divided between males and females. As one would expect, the majority of the cases were of the hip and knee, diseases of other joints

¹ An almost exactly similar case, under the care of Mr. Durham, at Guy's, is recorded in the Guy's Hospital Gazette, vol. vii., p. 189.

² Reported in THE LANCET, vol. i., 1876, p. 601.

³ This case is reported in THE LANCET, vol. ii., 1876, p. 222.

being, as a rule, treated as out-patients. There were four deaths. Ellen G—, aged thirty-nine; knee; died from phthisis. Llewellyn P—, aged fifteen; hip; from exhaustion. Richard T—, aged thirty-three; hip; suddenly, in convulsions, chiefly of the right side. Thomas O—, aged twenty-five; hip; exhaustion.

Nine operations were undertaken in this class, these cases being tabulated under the headings "Operations" and "Amputations for Disease." Remarks on the dressings and modes of operation will be found under those headings.

W. D—, aged fifty-seven; removal of a diseased astragalus. Patient recovered with a useful limb.

W. S—, aged forty-eight; disease of knee; Carden's amputation. Discharged with a capital stump in forty-eight days.

Leonard J—, aged five years and a half; diseased knee, with suppuration and external wound, and great exhaustion. Amputation by modified circular method above knee, and discharged well in forty days.

Albert W—, aged twenty-three; disease of knee; excision. Drainage-tube and carbolic-oil dressings. P. H. Watson's splint and gum-and-chalk bandage. Styptic colloid and charpie over line of incision, on removal of which some days after this line, except at its extremities, was found completely healed. This case failed from there being some slight movement at the knee, and he was to be admitted again for further treatment, but disappeared from observation.

The case of fibrous ankylosis at the hip and knee affords several points of interest. The patient was a woman, aged twenty-eight, whose confinement twelve months previously had been followed by severe pelvic cellulitis, with discharge of pus through the right groin. She had a miserable home, and had been badly attended to. On admission, the left knee extended to its utmost limit was ten inches from the bed level, and the right hip and knee were flexed to nearly right angles, and rotated outwards. After her general health had improved, she was placed under chloroform, the hamstring tendons on the right side divided, and the adhesions at the hip broken down by manipulation until the limb was in a fairly straight position. The adhesions at the hip gave way with a loudish crack, and without much force being used. Before the patient's removal back to bed a Liston's long splint was applied. On the evening of the day of operation, and all next day, the patient appeared in a most critical position, with a pulse of 164, scarcely perceptible, and complaining of great pain in the left knee, which was relieved by the removal of a splint previously applied. These alarming symptoms gradually passed away. No pain was complained of in the right limb until some days after the operation, and then not much, but she became unruly, and insisted upon having the splint removed, and would scarcely allow the limb to be touched from that time forward. The limb went back to its old position, the skin behind the right knee sloughed, an abscess formed here, the joint became disorganised, and she was rapidly losing ground. Amputation was advised, but she and her husband persistently refused their consent. Finally she rapidly regained strength, got fat even, and went out of the infirmary in the same state as she was admitted, so far as her deformity was concerned, much to my chagrin. It was a mistake to put the limb up in splints immediately, but I cannot think that this was the whole and sole cause of failure.

Hip cases are a severe strain upon the resources of a small institution like our infirmary, where we only make up from fifty to sixty beds, the town population alone being upwards of 80,000. Yet, surely, they are proper cases for in-door treatment. In order that they may be cured they require a certain line of treatment persistently carried out "under orders"; and this, considering the class of patients one has to deal with, cannot be done unless they are continually under intelligent observation, which cannot be the case at their own homes.

Hip cases, as a rule, were treated in the first instance by rest in bed and the application of Liston's long splint, or a weight and pulley, and subsequently by the application of a stiff bandage. One case, in a boy aged seventeen, was successfully dealt with by Sayre's splint. One knee case, in a female aged thirty-nine, died of lung mischief, the joint symptoms apparently improving. In an ankle-joint case in a man aged fifty-seven, the joint was cut into and the astragalus alone found diseased; this was removed, and he finally recovered with a useful foot. Carbolic oil was used, but not the spray or gauze.

In early knee cases the plaster-of-Paris or gum-and-chalk bandage has been chiefly resorted to. I prefer them to Hyde's poroplastic splints, which, after being worn for a short time, give way to some extent.

BURSÆ AND TENDONS.

Ditto: inner ankle.....	0 1	0 0	0 0	0 1
	2 4	2 2	1	5 6

In the first case the finger which was most in the way was amputated at the earnest request of the patient, and he was well satisfied with the result so far as improved use of his hand was concerned. The cases of housemaid's knee were cured or much relieved by rest.

	Under ten.	Under twenty.	Totals.
	F.	F.	F.
Varus	0	2	2
Equino-varus	1	1	2
	1	3	4

In the two cases of equino-varus the tendo Achillis was divided subcutaneously, and this treatment, with the subsequent application of stiff bandages, was successful in effecting a cure in one case, but in the other, aged eleven, owing to a difficulty with the parents, the child did not remain sufficiently long under observation to obtain a satisfactory result. The varus cases were mild; one, aged fourteen, was put on tonic treatment and frequent exercise under observation, and was discharged cured, without any operation. The other case was evidently hysterical, and was much improved by ten weeks' stay in the infirmary and general treatment.

Ulcers I have classified according to their seat. Twenty-one were in women and 34 in men. The three thigh cases were all in women. Ulcers of the leg, occurring in the middle period of life, made up the great bulk of these cases, and they were of the usual varieties—eczematous, varicose, simple, indolent, specific. The usual treatment of ulcerated legs has been rest in bed on an inclined board, cleanliness, bandaging, in some cases strapping, and various local applications according to circumstances—carbolic oil, lotio rubra, boracic ointment, zinc ointment, &c. One is well repaid by directing a little attention to these local applications; indeed in this, and in other directions of treatment, we are far too apt, from the cases being so common and so numerous, to lapse into a system of careless routine which is anything but beneficial to the patient. Carbolic oil is a useful early application in some cases, but it must be borne in mind that it delays cicatrisation, and when it has served its purpose, some other application, as *lotio rubra*, which is most useful in aiding granulation and cicatrisation, should be resorted to. Boracic ointment is a valuable application in some cases, and acts admirably as a deodoriser of foul discharges, or rather as a preventer of their becoming foul. I have not yet treated ulcers on Lister's antiseptic method, but intend doing so; *Martin's elastic bandage* has been chiefly of value in the varicose variety; in such cases it answers admirably. Where there has been any constitutional dyscrasia, obvious or suspected, *internal treatment* has been adopted

to aid the cure. If eczema is present, *arsenic* has been given with advantage; and so also *opium*, where pain is a dominant symptom. When the ulcer is specific *iodide of potassium* acts often like magic, and where there is any suspicion of such connexion it is wise to give it to aid the diagnosis. In some cases it clears up matters wonderfully. I have known cases which, after being under various kinds of treatment for a lengthened period, have healed up in a week or two under iodide of potassium and simple dressing. On the healing of varicose and some other ulcers, if you have an intelligent patient to deal with, I strongly approve of an *elastic stocking* being worn, but it should be adapted before the patient leaves the hospital, to ensure its fitting properly, and he should be cautioned about its proper use. In almost all cases, under rest, good and regular diet, and the avoidance of all irritating applications to the ulcer (which, as a rule, have been pretty freely applied before the patient's admission), rapid improvement is observed. In some cases of indolent ulcer, *blistering* has been followed by beneficial results. The application of a *splint* has sometimes been of value by keeping the parts at rest, and one obstinate case, where the ulcer was situated at the lower part of the back of the leg, was cured by relaxing the tendo Achillis by means of a slipper, and a strap extending from it to above the knee. The practice of *skin-grafting* has been adopted in suitable cases, and the results in some of them have been everything that one could desire. The heel case was chronic and extensive, the result of injury a long time previously. The patient had been unable to work for five or six years, and craved to have the foot removed. Amputation in the lower third of the leg, taking a long anterior flap, was performed antiseptically, catgut ligatures and sutures being used; the stump was dressed four times; the temperature was normal throughout, and in eighteen days the patient was up, being discharged with an admirable stump ten days later. One case of scrofulous ulceration of the face was attacked by erysipelas, and this case showed the value of aconite in small and frequently-repeated doses in this disease, for, under its use, in two days the temperature was normal. Nitrate of silver, four grains to the drachm, was applied, to see if it would stop the erysipelas from spreading. It did not have this effect, neither did I expect that it would. Aconite in small and frequently repeated doses, as advised by Ringer, will, as a rule in such cases, meet all the indications, without any other treatment, general or local.

(To be concluded.)

NOTES ON PATHOLOGY OF THE URINE.

By CHARLES A. CAMERON, M.D., F.R.C.S.I.,
PROFESSOR OF CHEMISTRY AND HYGIENE, R.C.S.I., MEDICAL OFFICER
OF HEALTH, DUBLIN.

SULPHURETTED HYDROGEN AND AMMONIA IN URINE.

I HAVE not met with any account of the persistent occurrence of free sulphuretted hydrogen in the urine, but a case of the kind has come under my own observation. A gentleman in the middle period of life, of active business habits, and discharging the duties of a most onerous public appointment, has been for many years past frequently under medical treatment. His complaints are always of a somewhat indefinable nature. He suffers from malaise, a painful feeling of fatigue, and sometimes from want of appetite, but he is rarely confined to his bed or even his room. He works away steadily. He has been treated medically by Dr. Samuel Gordon, ex-president of the College of Physicians, who has enabled me to make examinations of his patient's urine. Now, there was nothing peculiar in the urine with respect to its specific gravity, amount of urea, or other points, with but one remarkable exception: it contained free sulphuretted hydrogen the moment it was passed. On one occasion I had the opportunity of examining this urine within a minute after it had been passed, and found, both by chemical tests and by smell, the presence of free sulphuretted hydrogen in it.

The amount of sulphuretted hydrogen was determined on two occasions: on the first it was found to exist in the ratio of 1.4 cubic centimetres per litre, and on the second occasion 1.9 cubic centimetres per litre of urine. These pro-

portions are about one-third of the quantities found in very weak sulphuretted waters (Spas).

The period which elapsed after the discovery of the sulphuretted hydrogen in this urine until its disappearance was somewhat more than two years. During nearly the whole of this time the urine was never free from sulphuretted hydrogen; at least, every time it was examined or analysed such was found to be the case.

So soon as the sulphuretted hydrogen disappeared, its place was taken by ammonia; the instant the urine was passed it was found to have an ammoniacal odour. This state of things continued for about two years; but lately the urine has no longer an ammoniacal odour.

About the time that this sulphuretted hydrogen urine was being passed, Surgeon Hazleton of Westland-row, Dublin, introduced to me a young lady, from whose skin sulphuretted hydrogen was exhaled. I placed upon her skin pieces of bibulous paper, containing acetate of lead, and in the course of a few hours they were blackened. When she was warm after exertion the odour of sulphuretted hydrogen from her was unmistakable. Silver coins, thimbles, &c., kept in her pockets soon became black. She was in good health. Her urine contained no sulphuretted hydrogen; whilst, on the other hand, no odour of sulphuretted hydrogen could be observed from the skin of the gentleman whose urine contained sulphuretted hydrogen. In the case of the lady the exhalation of sulphuretted hydrogen lasted for about three years, and then completely ceased.

INTERMITTENT OCCURRENCE OF SUGAR IN THE URINE.

I make, now and then, examinations of the urine of a gentleman nearly sixty years old. Sometimes its specific gravity is from 1025 to 1037, and sugar in large quantity is present. At other times the specific gravity is from 1020 to 1023, but not a trace of sugar can be detected in it by any method. Sugar is more frequently present than absent. The quantity of urine passed per diem is generally, but not invariably, above forty ounces. Dr. Garrod has examined this gentleman.

LOW SPECIFIC GRAVITY OF DIABETIC URINE.

Many years ago I examined several times a week during some months the urine of a young man (a patient of Sir George B. Owens), who ultimately died from diabetes mellitus. As a rule, the specific gravity of his urine rarely rose higher than 1030. He had an incessant and unallayable thirst. On one occasion I found his urine to have a specific gravity of 1005, sugar being present in small but decided quantity. The low gravity of the urine surprised the medical attendant, who indeed at first was incredulous that diabetic urine could have so low a gravity. The specific gravity of the urine was carefully determined by the specific-gravity bottle and by the hydrometer, and, unless the patient put water into the specimen (which was highly improbable), there was no other source of error. On questioning the patient, he stated that on the day upon which the specimen of urine was passed his thirst was so great that he drank water incessantly. He believed that he must have swallowed a gallon and a half during the day.

FIFTEEN CASES OF DIPHTHERIA.

By FREDERICK H. DALY, M.D.

I CAN offer no explanation as to why such a number of cases of diphtheria should occur in my practice within a short period, while several medical men around in large practice, to whom I have spoken, have had no cases. It is also remarkable that my cases have very little relationship, as far as locality is concerned, and they all were in the families of well-to-do people. All the houses in which they occurred had two insanitary conditions—viz., first, there was only one common cistern for drinking and closet purposes; and, second, the sink in the kitchen or scullery communicated *directly* with the drains. I cannot help connecting this outburst of the disease with the prolonged drought which we have had, and the consequent want of flushing of the drains or sewers. I would call attention to Case 4, as proving that the incubation period of diphtheria may be only three days.

CASES 1 and 2.—On April 27th I was called to see two children in Bouverie-road, Stoke Newington, the house being the last but one in the road, having the open country beyond. The younger of the two, aged eight years, had been ill for four days, and had slept with her sister, aged ten years. Both cases were mild. There was a good deal of false membrane on the tonsils, fauces, and velum palati in the younger child, and on two occasions traces of albumen in the urine. In both cases the temperature varied from 101° to 103° , and the pulse from 120 to 130. The pulse of the younger child was very feeble during the second week, and there was considerable glandular enlargement in the neck. The treatment used in these two cases was large doses of tincture of perchloride of iron and chlorate of potash internally, and glycerine of carbolic acid applied to the throat. Ice to suck, and plenty of port wine, beef-tea, and milk. In this house I found that previous to the attack the closet had been out of order for a week. There was no water, from something having gone wrong with the closet-wire.

CASE 3.—On the 8th of May I saw for the first time Mrs. W—, aged sixty-eight years. She was visiting at Albion-road, Dalston. She complained of slight sore-throat and cough; she was a little feverish. On examination the throat was a little inflamed; there were other symptoms of catarrh. Ordered a saline mixture. On the 9th she felt much better, and the throat was comfortable. I did not therefore examine the throat. With the stethoscope I heard some coarse mucous râles. On the 10th there were more distinct bronchial symptoms, and *no complaint was made about the throat*. Ordered bark and ammonia. I saw her again on the evening of the 10th. She was then very restless and coughing; temperature $101^{\circ}8'$. On the morning of the 11th, at 11 A.M., I again saw her. She was much worse, and complained of her throat, and of great difficulty of swallowing. I found now that both the tonsils and the back of the fauces, as far down as I could see, were covered with a thick diphtheritic exudation. The pulse was good and the temperature slightly subnormal. To take as much stimulants as possible. At 4 P.M. Dr. Wilson Fox saw the lady with me. She had grown worse rapidly since the morning; the disease had extended to the larynx, the face and left hand were getting livid, and very little air entered the left lung. The question of tracheotomy was discussed by Dr. Wilson Fox and myself, and decided against. The patient died during the evening.

CASE 4.—Miss W—, daughter of the last patient, came to be with her mother on the 10th of May, and certainly kissed her mother on that day. I saw this lady on the evening of May 13th, exactly three days from the time she came to attend her mother, and she had undoubted diphtheria. There were distinct patches of false membrane on the throat. Temperature 103° . She was removed the same evening into a private ward in a hospital, and recovered.

CASES 5, 6, and 7.—These occurred at the same house in Mountford-road, Hackney. Mrs. B—, who had been confined on the 6th of May, complained of sore-throat on May 15th, so also, on the same day, did her eldest son, aged eight years. Both cases were slight, and there was not much exudation on the throat. On May 19th, four days after the mother was taken ill, the nurse called my attention to the infant's navel. The funis had separated, and round the navel was a red circle as large as the top of a tumbler, and this was covered with a shreddy diphtheritic exudation perfectly characteristic. It was not easy to examine the throat, but, as far as I could see, there was membrane there also. The infant died on the fourth day. The mother and son recovered. The treatment was the same as in cases 1 and 2.

CASES 8, 9, 10.—I was called on the 14th of May to see Mrs. G—, living in a large roomy house, having the open country behind it, in Lordship-park, South Hornsey. I found her suffering from a severe attack of diphtheria. She was very ill, temperature $103^{\circ}2'$, with a good deal of exudation on the throat. The glands of the neck were intensely painful and much swollen. She recovered very slowly, and is much shattered in health by the attack. No albumen and no paralysis. She was of course isolated, but on the 22nd her second daughter, aged thirteen years, was attacked very seriously. The entire throat was covered with false membrane, which extended over the roof of the mouth. Temperature $102^{\circ}2'$; pulse 112; the latter became so feeble after a few days that it could scarcely be felt. Urine feebly albuminous twice. Could only swallow with the greatest difficulty. Glands painful, and considerable aphonia. The treatment was, as in the other cases, plenty of wine, steel

and chlorate of potash, ice, beef-tea, milk, and glycerine of carbolic acid applied to the throat; she also had the throat frequently sprayed with warm Condy's fluid and water. She is recovering slowly, the pulse being still almost imperceptible. On May 28th, her sister, aged fourteen years, had several characteristic patches on the throat, but was not at all ill. Temperature 99° ; pulse 80. The state of the throat continued for several days, and then cleared off, the patient all the time feeling fairly well.

CASES 11 and 12.—Agnes B—, aged eight years, was attacked with a sickness and sore-throat on the 25th of May. She had had scarlet fever two years back, but her mother thought she must be getting it again. Her temperature was 103° ; pulse 120. There were several large diphtheritic patches on the throat, the tongue was swollen, and she could scarcely swallow. The urine was highly albuminous. The treatment was the same as in the other cases. On the fourth day her nose bled profusely. She said she felt much better. The throat cleared; the temperature was 98° ; pulse 76. The albumen disappeared from the urine, and, beyond weakness, the patient was well on May 31st. Her sister Lilly sickened two days later, and made a speedy recovery.

CASES 13, 14, and 15.—These were all mild, requiring no particular remarks. One was in Albert-road, Dalston, and the house was nearly opposite to that in which cases 11 and 12 were. The other two cases were in Stoke Newington.

It will be seen by the above necessarily brief notes (for I have omitted all details) that in less than a month fifteen cases of diphtheria occurred in my practice, two proving fatal. In all the cases isolation was insisted on, and disinfection with carbolic acid carried out fully. I also advised the various members of each household to gargle their throats very frequently with Condy's fluid and water, and to these precautions I attribute the escape of the other members of the different households. In the houses in Albert-road, there were eleven persons living in one house, and only one had the disease, and in the other house eight persons lived, and but two had diphtheria. None of the patients have as yet developed diphtheritic paralysis.

Queen's-road, Dalston.

TARSAL TUMOURS TREATED BY ELECTROLYSIS.

By JULIUS ALTHAUS, M.D.

ON February 6th, 1880, Mr. White Cooper sent a lady, aged thirty, to me, who suffered from tarsal tumours occupying nearly the whole of both upper eyelids, and which had become gradually developed during the last six months. They looked inflamed, were very disfiguring, and caused considerable annoyance by interfering with the proper action of the eyelids, which felt very heavy. Under these circumstances Mr. White Cooper recommended the removal of the growths by electrolysis. As the conjunctiva was involved by the tumour and was excessively sensitive, reflex action in the lid being very much increased, I thought it best to perform the operation under anæsthesia, and therefore procured the assistance of Mr. Clover, who put the lady very quickly under the influence of his anæsthetic mixture. I then applied both poles of the voltaic battery by means of my four-pointed electrolytic needle-conductors alternately to both tumours, so that each of them received the influence of the cathode and anode successively. Twenty cells of Becker-Muirhead's battery were used for ten minutes, after which the whole of the tumours, both inside and outside, appeared completely shrivelled up.

Not a drop of blood was lost at any stage of the operation, which was particularly remarkable when the subconjunctival portion of the tumour was acted upon, as this was highly vascular. The surface of the lids was covered by goldbeater's skin and flexile collodion. The patient recovered quickly from the influence of the anæsthetic, and went the same afternoon to her home in the country. She called upon me again on March 4th, about a month after the operation, when I was gratified to find that the success had been complete. The tumours had entirely vanished; no scar was visible anywhere, and no eversion of the lids had occurred. Both eyelids had, indeed, a perfectly normal appearance.

Tarsal tumour is a troublesome affection and does not yield to external applications, such as the red precipitate or iodide

of potassium ointment; so that, if removal becomes necessary, free incisions have to be made which are generally accompanied by considerable bleeding. The adhesive inflammation which supervenes upon the operation has sometimes to be increased by touching the interior of the cysts with nitrate of silver; and if the tumour be situated near the margin of the eyelid and the punctum, there may be cicatricial shrinking after the operation, and eversion of the edge of the lid, with displacement of the punctum. All this makes the ordinary operation for tarsal tumour a somewhat formidable one; and electrolysis would therefore appear far preferable. The complete absence of bleeding in the latter procedure is a great advantage, as the operator sees much better what he is doing, and can regulate the action of the galvanic force with the greatest nicety. A single application appears to be sufficient for a cure, and there is no danger of cicatricial shrinking afterwards, provided the operation be properly performed. In a case where only the skin of the eyelid would be affected, I should not resort to anæsthesia, as then the pain would not be severe; but the great sensitiveness of the mucous membrane in the above case rendered anæsthesia desirable.

Bryanston-street, Marble Arch, W.

A Mirror

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. GEORGE'S HOSPITAL.

THE following are among some of the cases, under the care of Mr. CARTER, in the Ophthalmic Wards.

SOFT CATARACT IN ONE EYE, AND A HIGH DEGREE OF MYOPIA IN THE OTHER, BOTH RECENT.

The patient, a man aged twenty-four, eighteen months ago was tested for the army, and the sight of each eye was found to be perfect. Five months ago he noticed that the sight of the left eye was failing, and a month later that he had a difficulty in making out distant objects with the right. When admitted, the right eye was much larger than the left, especially in the antero-posterior diameter. Myopia = 16 D, and there was a large posterior staphyloma. The left eye resembled a hypermetropic eye in size and shape. The lens was universally opaque. The latter was removed by suction.

DISLOCATION OF THE LENS INTO THE VITREOUS.

The patient, a man aged sixty-four, received a blow on the eye. Vision was immediately reduced to perception of light. When admitted, there was conjunctival injection, a tremulous and inactive iris, and the fundus oculi could not be illuminated. Four days later, no details of fundus were visible, and there were floating filaments in the vitreous. The lens was not visible. Vision: counts fingers at three feet.

VICTORIA DOCK DISTRICT DISPENSARY.

CASE OF MALFORMATION OF HEART AND ABSCESS OF BRAIN; UNUSUAL CONTENTS.

(Under the care of Mr. JULIUS CÆSAR.)

E. M—, aged nine, first came under observation in December, 1879, with the following history:—He was a full time and healthy child when born. At three months old his mother noticed that his cheeks, a circle round lips, the tips of fingers and nails, were very blue, and that the colour increased if he were excited or cried. At the same time the ends of the fingers and the toes began to enlarge.

These symptoms increased, but otherwise he appeared to enjoy good health up to about twelve months old, when a discharge, not offensive, from the left ear took place. At this time, also, he used to clutch his head as if it were the seat of great pain, and when old enough to make himself understood used to complain of great pain there. When

eighteen months old he had measles, bronchitis, and pneumonia, but appeared to recover from them fairly well. When three years old he had completed dentition. The discharge from the ear now ceased, and he began to walk; he was not at any period able to walk more than half a mile without fatigue and difficulty in breathing. Between five and six years his mother noticed, for the first time, that he dragged his right leg as if he had not power at the hip to lift it. Shortly after this his right wrist began to fail, then his forearm, and, finally, his entire arm. Then the leg became affected, the paralysis appearing to begin in the hip, and gradually extending to the foot, till at seven years and a half he had lost all power over these extremities, which about this time got acutely sensitive, so much so that the least movement of them caused him to cry, even touching them appeared to give him great pain. He had never talked plainly, but about seven years his articulation got very difficult and hesitating, till at last he could utter only half words. As for "mother" he used to say "mur," and for "father" "f-a-a." At all seasons of the year he felt cold to the touch, and used to complain of feeling cold, though clothed in flannel.

On August 18th last he had a convulsive fit during the night. When seen in the morning he was in bed comatose, and quite unconscious, the pupils were widely dilated, and his forehead suffused with a very deep blush. The pulse was rapid, full, and strong. He was unable to swallow even liquids. All his evacuations were passed involuntarily. He remained in this state for five days, and then appeared to get a little better, took some milk and egg, and seemed to recognise those about him. This continued for three days, when he relapsed into his former state of unconsciousness, which lasted till he died on August 31st.

At the necropsy thirty hours after death the pulmonary artery was found to communicate with the aorta a little way above the attachment of the two most left semilunar valves by an opening about the size of a sixpenny piece. These valves were perforated in several places. The ascending part of the aorta was as big as that of an adult. No murmurs were heard during life. The right lung was adherent to the thoracic wall and diaphragm, and both were the seat of tubercle. In removing the brain great difficulty was experienced in detaching the calvaria, so adherent was the dura mater to it. On examining the brain tubercles were seen scattered all over the base, and in the ventricles and fissures of Sylvius. The right hemisphere of the cerebrum was quite pulpy, the anterior part of the left hemisphere was in a like condition, but the middle and posterior lobes were quite hard except at one spot in the latter lobe, which was quite soft and fluctuated on pressure. On cutting into this spot it proved to be a large abscess extending from the middle cornu to the posterior cornu of the lateral ventricle, but not entering it. On examining the abscess it was found to contain a dense calcareous mass weighing 120 grains. The walls of the abscess were impregnated with a like material, and grated on the knife when cut. The remainder of the brain presented no pathological changes of importance.

Remarks.—The principal points of interest in this case were (1) the unusual form of heart malformation; (2) the existence of large perforations in the semilunar valves, unaccompanied by murmur; (3) the existence of so much brain mischief with comparatively so few symptoms.

QUEEN'S HOSPITAL, BIRMINGHAM.

COMPOUND COMMUNUTED FRACTURE OF THE HUMERUS; LISTERISM; RECOVERY.

(Under the care of Mr. JAMES F. WEST.)

THE following cases, of which the notes are abridged from those taken by Mr. J. W. Moore, house-surgeon, serve to illustrate the advantage of the antiseptic treatment in severe compound and comminuted fractures.

Charles F—, aged thirty-five, a saddler, was admitted on July 10th, 1880. He had been thrown off the top of an omnibus, and had fallen with his left arm doubled under him. The humerus was fractured just above the insertion of the deltoid, and again about three inches lower down. There were two small wounds on the inner side of the arm at the upper third, a little towards the back. He had lost about a pint of blood, and there was considerable shock. A piece of bone, about two inches in length and one-third of the circumference of the shaft of the humerus, protruded

from the upper wound, and, being loose, was easily removed; it was quite denuded of periosteum.

The patient was at once placed in bed; the wounds were syringed out with carbolic-acid solution (1 to 50), a fine silver suture was introduced into each wound, and the protective gauze &c. were applied after Lister's method, under the spray. The arm and forearm were bandaged in the extended position, with an inner and an outer straight splint, the limb being elevated and placed on a pillow. Evening temperature 98°4; pulse 110. He had a comfortable night, and the temperature next day was 99° in the morning and 99°8 in the evening. Pulse 100; respiration 24.

The wound was dressed for the first time (under spray) on July 12th, when the sutures were removed, and a small drainage-tube was introduced into the upper wound. Evening temperature 100°; this was the highest temperature registered. The patient was comfortable and free from pain.

On the 13th and following days the temperature was, without a single exception, normal.

The wound was dressed for the second time on the 15th; the lower wound was healed and the upper wound discharging only a little serum, and there was no pain excepting when the wound was dressed. The third dressing was on the 19th, under spray. A small quantity of pus was found on dressings, but there was no redness, oedema, or tenderness up the arm. It was dressed again on the 23rd, when there was scarcely any discharge of pus. The drainage-tube was left off. An inner splint of gutta-percha (with a window in to dress the wound) was made, extending from the axilla to the wrist, and embracing half the circumference of the limb, the long straight splint on the outer side being still retained. The wound was now easily dressed without any disturbance of the parts, and on the 30th, as it was quite sound, dry carbolic gauze was substituted.

On Aug. 2nd the wounds were quite solid; the forearm was bent to a right angle with arm. Gutta-percha splints were applied, and the patient was discharged in good health. The arm was in good position, and a fair amount of union had taken place. He attended as an out-patient for the next few weeks, and at the end of two months was able to resume his trade.

WOUND OVER THE PATELLA, WITH A SMALL PIECE CHIPPED OUT OF THE PATELLA; LISTERISM; RECOVERY.

(Under the care of Mr. JAMES F. WEST.)

Geo. J—, aged forty-two, a horsekeeper, was admitted on July 19th, suffering from a kick over patella from the hind leg of a horse. The wound was one inch in length, transverse, and had contused edges, all structures being divided down to bone, and a small splinter being chipped out. The bursa patellæ was readily explored with finger. The wound was syringed out under spray with carbolic lotion (1 to 50), and two silver sutures were applied. No drainage-tube was inserted. Dressed antiseptically. A Back splint was applied and the limb fixed with sand pillows, and he was confined to bed. The temperature was never higher than 99°. The patient slept well, and had no pain worth mentioning. He was dressed for the first time on the 21st, when the wound looked well and was free from redness and irritation. He was again dressed five days afterwards, and the sutures were removed; the wound was healed. At the next dressing dry gauze was placed on the wound. The patient was discharged cured on Aug. 2nd, with a cicatrix firm and solid, and the skin freely movable over patella. At no period had there been any buritis or synovitis. The patient was ordered to wear the back splint for a few days longer.

NEWARK HOSPITAL.

FRACTURE OF INNER CONDYLE OF RIGHT HUMERUS;
PERFECT UNION.

FOR the notes of this case we are indebted to Mr. J. D. T. Reckitt, house-surgeon:—

Henry G—, aged nine years, was seen as an out-patient on April 20th, 1879. He stated that whilst running at full speed he fell down, with both arms extended, and that the inner sides of both elbows came into violent contact with the pavement. There was great swelling of the elbow and parts about the inner condyle of the right humerus; motion of the elbow-joint was somewhat impaired and very painful. Upon close examination, the inner condyle was found to be

broken off and quite movable beneath the integuments, but there was not sufficient broken off to involve extensive fracture into the elbow-joint.

An inner angular splint was applied, and a pad of lint to maintain the broken fragment in position. The arm was kept at perfect rest, and cold lead-lotion applied. The swelling and pain quickly disappeared, and on May 15th the splint was removed, the condyle having become firmly united and not to be detected by manipulation. Passive motion was applied, and in a week longer he was able to use the arm as usual.

Remarks by Mr. RECKITT.—That bony union occurred so soon after the injury was somewhat surprising, more particularly as the boy was only just recovered from a very severe attack of typhoid fever; and in these particular fractures union, I believe, is often difficult to obtain and sometimes not obtainable.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Amœboid Movements of the Colourless Blood-corpuscles in Leuchæmia.—*Nature and Treatment of Genu Valgum.*

THE ordinary meeting of this Society was held on the 9th inst., J. E. Erischen, Esq., F.R.S., President, in the chair. A suggestive contribution to the pathology of leuchæmia was made by Dr. Cavafy, who has observed a remarkable lack of amœboid movements of the leucocytes in a case of this disease. A paper by Mr. Brodhurst upon genu valgum, in which he discountenanced osteotomy, gave rise to a rather spirited discussion, Mr. Savory supporting the author in his strictures upon the prevalent practice of this operation, which was, on the other hand, upheld by Mr. Barwell and Mr. Parker, and, with certain reservations, by Mr. Haward.

A paper was read upon "Amœboid Movements of the Colourless Blood-corpuscles in Leuchæmia" by Dr. JOHN CAVAFY. The observations described in this paper were made on the blood of a patient suffering from leuchæmia, who was in St. George's Hospital, under Dr. Whipple, from April 30th to July 18th, 1879. The patient, a man aged twenty-six, states that he had been well, with the exception of occasional sick headaches, until a month before admission, when he began to feel extremely weak and languid. He got a cough a little later, and a week before he came he had hæmorrhages in the conjunctivæ and skin after severe retching. On admission he was found to be very pale, mucous râles were heard over the lungs, and a soft systolic murmur at the base of the heart. There were enlarged lymphatic glands in the axillæ, over the right clavicle, and in the right groin. The blood contained a large excess of colourless corpuscles, the proportion to the coloured being as one to six. During his stay in the hospital he became gradually worse, with occasional temporary improvement. He had epistaxis, and fresh hæmorrhages in the conjunctivæ and skin on several occasions. The spleen was not at first enlarged, but became so later, as also did the liver. The glands subsided a little at first, but again soon enlarged, and fresh ones appeared, especially in the neck and near the angles of the lower jaw. The pulse was always quick, and the temperature nearly always above normal. After leaving the hospital he improved slightly at first, but soon became worse again; the glands became of enormous size; there were numerous cutaneous hæmorrhages, and he became gradually weaker, dying early in October, 1879. There was no post-mortem examination. The blood was examined to determine whether the amœboid movements, which characterise healthy colourless corpuscles, were preserved. Twelve observations were made in all, at various intervals, from May 16th to July 14th,

the hot stage being used. The total number of colourless corpuscles in the field of the microscope was first counted, and the number of amoeboid corpuscles noted about every ten minutes, usually for half an hour on each occasion. The mean of these was then taken, and the percentage calculated, the results being tabulated in the paper. In determining whether amoeboid movements occurred, a very slight departure from the spheroidal shape was considered sufficient; but other observers might have been disposed to refer some of these very slight changes of form to pressure of the cover-glass, which would reduce the proportion recorded in the table. It was found that the character of the movements was much changed when they occurred at all, as they were very sluggish and ill-marked, although the observations were made at fever temperatures which stimulate normal corpuscles to great activity. It only now and then happened that one or two corpuscles showed comparatively active motions. The blood contained the three kinds of colourless corpuscles which have been found in health—lymphoid cells, ordinary colourless corpuscles, and rarely one or two large granular cells. Amoeboid specimens of each were found, but the first and the last kind showed mere traces of movement. It was found that coagulation took place much more rapidly in the later than in the earlier specimens. The table shows that only a very small proportion of the corpuscles was amoeboid, the highest found being 24 per cent., and the lowest 4 per cent. The proportion also decreased with the advance of the disease; the mean of the first six observations being about 12 per cent., while that of the last six only gives 6 per cent. As the first observations were made in a comparatively late stage of the disease (after the occurrence of hæmorrhage), further investigation must decide whether loss of amoeboid movement takes place at the earliest onset; it is very probable, however, that this will be found to be the case. For purposes of comparison the blood was examined in two cases of chloro-anæmia, and one of anæmia with leucocytosis from cancer of the stomach, and in all three amoeboid movements were active at ordinary temperature. The earliest observations on the point brought forward in this paper were made by Dr. Laking in 1873, but remained unpublished. The results were communicated by Dr. Pye-Smith to the Pathological Society in 1878, and in the same year to THE LANCET by the author of this paper. Neumann, also in 1878, found amoeboid movements wanting, or very sluggish, in a case of leucæmia, although they were active in the corpuscles of fluid from blisters in the same individual. The following conclusions may be drawn:—1. The colourless corpuscles in leucæmia are dead or dying, and hence incapable of development. 2. Amoeboid movement being practically lost, emigration from the blood-vessels is impossible. 3. Coagulation and thrombosis are largely favoured. Secondary leucæmic nodules and infiltration must be produced, not by emigration, but by extravasation, and probably also by lymphatic accumulation, as large numbers of cells must be prevented from entering the blood by lymphatic thrombi. Whether lymphatic new-growth also takes place must be decided by careful examination as to the presence of a true adenoid reticulum, and must be rejected if we find only a network of fibrin. In conclusion, it is pointed out that the absence of amoeboid movement may prove of great value in diagnosis, as serving to distinguish cases of true leucæmia from leucocytosis, a matter in which there are oftengrounds for hesitation. —Mr. SAVORY inquired whether the number of red blood-corpuscles was absolutely or relatively diminished, as if the leucocytes were inactive or dead this should affect the genesis of the red corpuscle.—Dr. SILVER said that in a case of lymphatic leucæmia recently under his care the white corpuscles, which were of various sizes, exhibited unusually active movements at ordinary temperature. The same occurred in a case of splenic leucæmia under Dr. Green's care. In both cases there was also a marked tendency of the red corpuscles to become fused into irregular masses, a change observed also recently by a Dublin physician in a case of essential anæmia. Of course it would not be right to draw conclusions from single cases.—Dr. PAYNE said that some years ago he made a post-mortem examination at St. Mary's Hospital on a man who died from exhaustion following a simple fracture of the femur. Around the fractured ends was a mass of soft imperfect coagulum; there was no true coagulum, no suppurative, no attempt at repair. It seemed to be a striking instance of want of "vitality" of the leucocytes, not permitting of the usual changes of repair.—Dr. CAVAFY, in reply, said that he had

not studied the red corpuscles in this case, but had observed simply the amoeboid movements of the leucocytes. The proportion of white to red corpuscles was 1 to 6. Dr. Silver's cases were interesting, and seemed opposed to his own observations, but they may have been in an earlier stage of the disease than in the case he had observed. Neumann had noticed the want of amoeboid movements in the white corpuscles in leucæmia, and Dr. Shann was at present observing a case at Addenbrooke's Hospital in which only a small proportion of leucocytes showed movements. Dr. Payne's observation tended to show that want of repair in the fracture was due to loss of vitality of the colourless corpuscles. The matter was open for further investigation.

A paper followed by Mr. B. E. BRODHURST, entitled "Observations on the Nature and Treatment of Genu Valgum." Genu valgum is regarded rather as a constitutional than as a local defect. It is accompanied by a relaxed condition of the ligamentous system, and it is preceded by flat foot. Thus the tibia is inclined outwards, and the weight of the body is thrown unduly to the inner side of the limb. The internal lateral ligament of the knee-joint consequently yields, and the inner condyle protrudes. The condyles of the femur are thus placed in an oblique position from without inwards, and from above downwards. There is usually a difference in the length of the condyles, the inner being about three-tenths of an inch longer than the outer. Sometimes, however, it is five-tenths of an inch, and again not more than one-tenth of an inch. This is observed both in the rickety and in the healthy femur. Examples are to be seen also where the difference in length between the inner and the outer condyle is almost inappreciable, and again other rare specimens exist where the inner condyle is fully one inch longer than the outer, and is misshapen. Knock-knee in its early stage disappears in the horizontal position, and can only be distinguished when the patient is erect, when, at length, it has become permanent, firm support is sufficient to remove it. But as the deformity increases and the femoral condyles become more oblique, the biceps femoris is rendered tense, the ilio-tibial band becomes tightly drawn, and the external lateral ligament is rigid. The question to be solved is, how is the limb to be restored so that a right line, passing, as in the normal condition, through the long axis of the femur and of the tibia, may strike on the top of the arch of the foot. In the first place it is necessary to remove the flat foot, or in other words, to restore the arch of the foot. Various modes have been adopted to restore the straight line of the limb; for example, forcible straightening, osteotomy, and tenotomy. 1. Forcible straightening has been employed both in young children and in adults. It is effected with considerable injury both to the bony structures and to the soft parts; but, according to M. Delore, permanent injury is not produced, and his patients are again able to walk in the course of six months. 2. Osteotomy has lately been performed by some surgeons in every case of genu valgum, even when the deformity was yet very slight, and the child only between three and four years of age. One operator claims to have performed osteotomy for genu valgum on nearly four hundred limbs. And it is not that one section alone is made, but perhaps three, or even four, are executed on the limb at a sitting. Notwithstanding these osteotomies on the condyle and on the shafts of the femur and the tibia, the deformity often remains almost as great as before the operation. And when the limb appears to have been straightened the deformity recurs, and the malleoli are seen several inches apart. Further, genu varum may be substituted for genu valgum. Also, partial ankylosis is not unfrequently induced, and the motion at the joint is much impeded. The growth of the limb also is interfered with, and a serious lameness is begotten where there was previously no lameness. Fatal blood-poisoning, also, has resulted more than once from these operations. 3. It is shown by a cast of a valgous knee which was taken when the patient was nearly eighteen years of age, that a very serious deformity existed, the inner malleolus being ten inches and a half removed from the median line. In this case the biceps tendon, the ilio-tibial band, and the external lateral ligament were divided, and the knee and the foot were brought, in the course of seven weeks, into their normal positions. When splints are insufficient to redress the limb, division of the tendon of the biceps femoris usually enables the limb to be straightened until adult-life is attained. But when in addition to the biceps the external lateral ligament and the ilio-tibial band are divided, the

knee may be straightened either immediately or gradually. In the adult gradual straightening is to be preferred. Any abnormal motion after division of the ligament is due to the lax condition of the internal lateral ligament, but this gradually lessens and at length ceases; unless the arch of the foot be raised and the retraction of the biceps be overcome, the inclination outwards of the tibia and the fibula must remain, notwithstanding osteotomy. In conclusion, it is stated that forcible straightening of the limb (*redressement brusque*) is unjustifiable; that osteotomy is wrong in principle and unnecessary, and that in children especially it is objectionable; but that division of tendons and fasciæ may be done without danger, and that through tenotomy we are able to reduce this deformity and to restore the thigh and the leg bones, and the bones of the arch of the foot to their normal positions.—The PRESIDENT said the paper contained several points of practical interest. He could confirm from his own experience the statement that genu valgum is often preceded by flat foot. As to osteotomy, there was no doubt as to evil consequences—even death—following an operation in which the knee-joint must be opened, and he hoped that surgeons who practised it would give their experience.—Mr. WARRINGTON HAWARD agreed as to the variations in the causes of genu valgum, many factors entering into its production. In some cases the ligaments, in others the bones, were at fault; and other cases were due to general debility. It was not, then, possible to lay down a special form of treatment to suit all cases. The examples of this affection might be divided into two sets—viz., those met with in young children, and those in subjects at or about the time of puberty. In young children rickets was a chief element in causation, the knock-knee being only one manifestation of the general condition. Such cases were to be treated constitutionally, the only local procedure necessary being to apply splints and to prevent the child bearing weight on its legs. On the other hand, the genu valgum that occurs in young growing ill-nourished girls and boys about the age of fifteen is mostly associated with flat foot and lateral curvature. There is little bony deformity, but laxity of ligaments and muscles. There are many cases in young rickety children with considerable knock-knee and but little flat foot, which could not be regarded as a factor in the production of the knee-deformity. In such cases there was marked elongation of the inner condyle, and it seemed reasonable to act on the condyle rather than on the tendon, which is not contracted. In such a case, of which he mentioned an example, it is impossible to forcibly straighten the limb. At the same time he had met with but few cases calling for osteotomy. In one case, which seemed most suitable for this operation, he was unable to perform it on account of the opposition of the parents, and after persevering by means of splints, a very satisfactory result was obtained. In another case of elongated condyle with lax ligaments following rheumatism, the limb was straightened after chiselling through the condyle; but the deformity returned as soon as the support was left off, owing to the laxity of the ligaments. There were cases, however, which were rightly treated by osteotomy; but he maintained it was incorrect to speak of this as an extra-articular operation. It was impossible, even on the exposed bones of a dead subject, to chisel off the condyle without opening the joint.—Mr. R. PARKER agreed that constitutional causes were largely at work in the production of genu valgum, and also laxity of ligaments; but there were other factors also. Flat foot was by no means often met with; when it occurs it follows rather than precedes the deformity produced by genu valgum. Mr. Brodhurst admitted there was lengthening of the inner condyle in a certain number of cases. Whether the lengthening be primary or secondary, it was not possible to straighten a limb with this condition unless very great violence were used; and Ogston's operation was directed to remedy this cause of the deformity. When the operation was carefully performed, the limb could be got quite straight; but of course, if care were not taken subsequently, it might relapse; and he attributed failure to the lack of continued supervision of these cases. He had never regretted operating for genu valgum in young children, who make good recoveries; and he did not regard osteotomy as more serious than tenotomy was in the early days of its introduction into surgery. He did not think osteotomy could be compared to the plan followed by Mr. Brodhurst, which, answers in certain cases; and it was not correct to say that osteotomy was now done in all cases of genu valgum. Mr. Brodhurst's plan had been practised for a very long time;

osteotomy was only recently introduced, and the great incentive to its performance was the insufficiency of the old method to cure the deformity.—Dr. E. HAUGHTON testified to the success attending Mr. Brodhurst's plan in a case in which it was adopted in preference to osteotomy, as being less free from danger. It was a bad case of genu valgum; and the limb was maintained in splints after the tenotomy, the splints being subsequently replaced by iron supports, which had now been removed.—Mr. BARKER said that no doubt some ill results had followed Ogston's operation, and some might have been unrecorded. But what had been the experience of the surgeon mentioned by Mr. Brodhurst, who had had three hundred of these cases? When looking up the subject after the fatal case which occurred in his own practice, he found records of one hundred and eighty cases, the only fatal ones being his own, and one dying from renal disease six weeks after the operation. A mortality of one per cent. could not be considered high even in minor operations. About a year ago he saw a case which had been treated by Mr. Brodhurst by tenotomy some eighteen or nineteen years previously. The patient was wholly unable to walk without a support, having worn a splint all the time, and much wished further measures to be taken; but owing to the laxity of the ligaments he was compelled to advise against osteotomy, and the patient was left unrelieved.—Mr. SAVORY concurred with Mr. Brodhurst in the opinion that osteotomy was being far too frequently performed. It was a "fashionable" operation, and every week case after case is recorded of "success" following it, so that one was tempted to ask what was meant by "success." If the patient escaped with life and limb, that was styled a brilliant success! Two things were to be considered, one was the use of the limb, the other its form or beauty. In a certain number of cases the latter was improved, but as to usefulness of limb (infinitely more important), those who record the successes give no definite information as to how far such people could walk before operating, and how far after? To the working classes it was of especial importance. He knew of one case, a postman, who could walk his ten miles a day before he was operated on, but since then he has never reached that. Surgeons who perform osteotomy to relieve this deformity should not record as a success the mere improvement in the shape of the limb, but should see that its utility was increased, and not diminished.—Mr. BARWELL said that in his experience flat foot was, as Mr. Parker had rightly said, secondary to knock-knee, and not a factor in its production. In many children the tibia becomes so curved from the genu valgum that the foot gets flat. There was undoubtedly, in many cases, very evident laxity of the ligaments, especially the external lateral. He believed the lengthening of the condyle was apparent and not real; it was due to obliquity of the epiphysis at its junction with the shaft of the femur, and he had produced the deformity artificially by driving in a wedge into the bone so as to produce obliquity. He had also found by experiment that with a femur fourteen inches long, and a tibia thirteen inches, and a deviation of eight inches, in order to remedy the deformity by adduction of the tibia it was necessary to separate the outer condyle an inch and a half from the tibia. During life this was done by Mr. Brodhurst by dividing the lateral ligament, the ilio-tibial band, and biceps tendon; and he did not see how this could add to the security of the limb. Mr. Brodhurst showed a case at the Clinical Society a year ago where this had been done, and the patient was unable to walk without support. For himself, he would much prefer to have his femur divided than the ligaments, especially if the knee-joint had to be torn asunder to get the limb straight. In reply to Mr. Savory, he could tell him of cases, and show him patients, in which the utility of the limb was greatly improved by the division of the femur. As an example, he quoted the case of a young lady, who before operation could not walk a hundred yards, but who afterwards was enabled to climb a mountain at Penmaenmawr, and who walks now five or six miles daily. (In reply to Mr. Savory, Mr. Barwell said this was certainly the case.)—Mr. BRODHURST, in reply, said he knew there would be difference of opinion on the subject. He agreed with Mr. Savory that osteotomy was overdone. He had seen several cases where it had failed, and he mentioned one. No doubt, occasionally genu valgum precedes flat foot; but the reverse is the rule—it is so in ninety-nine cases out of one hundred. The case shown at the Clinical Society was a girl of eighteen, and it was only six weeks after operation.

MEDICAL SOCIETY OF LONDON.

Tumour of Cerebellum.—Mitral Stenosis.—Reduplication of Cardiac Sounds.

AT the meeting of this Society on the 8th inst., the President, Mr. F. J. Gant, in the chair—

Dr. DOWSE read notes of a case of Tumour of the Cerebellum. A man, thirty-four years of age, who contracted syphilis ten years ago, began to suffer from ptosis of the left eyelid at the end of last year, followed by failing vision, first of the left and then of the right eye; he had also diplopia. In July severe headaches set in, and his gait became staggering; and occasionally he suffered from stiff neck, with retraction of the head. There was atrophy of both optic discs, especially the left. There was partial deafness of both ears; but with the exception of numbness of the fingers, sensation was normal. Memory was defective. On standing or walking there was weakness in the lower limbs with defective volitional co-ordination. There was complete absence of patellar-reflex. There was probably then a growth (possibly syphilitic) in the middle lobe of the cerebellum. The absence of tendon-reflex did not necessarily point to spinal disease, but it might be due to an inhibitory power exerted in the cord, preventing reflex action.—Dr. DAY doubted whether there was sufficient evidence of its syphilitic nature; and pointed out the difficulty in diagnosis between the headache of cerebral congestion and that of nervous exhaustion. He mentioned a case of cerebellar tumour where there was no headache.—Dr. GILBERT SMITH said there was in the London Hospital at present a patient suffering from cerebellar tumour, in whom there was marked reeling gait, slurred speech, impaired memory, and double optic neuritis, although vomiting, headache, stiff neck, pain on pressure, and paralysis were absent. Patellar-reflex was exaggerated.

Dr. SANSOM narrated a case and exhibited a specimen illustrating a mode of Causation of the Murmur of Mitral Stenosis. The patient manifested a systolic murmur with maximum at the base; at the apex a short murmur was interpolated between the second sound and the first sound, a pause preceding and succeeding it. This was found at the autopsy to be due to "buttonhole" constriction of the mitral valve with extreme dilatation of the auricle. It was obvious that the murmur heard during diastole was due to the flow through the mitral orifice unaided by the auricle. The rhythm of the murmur following the second sound exactly resembled that of reduplication of the latter.

Dr. SANSOM also read a paper on the causes and significance of Reduplication of the Sounds of the Heart. He first reviewed the various theories adduced in explanation of doubling of the first sound. These might be reduced to two. 1. That reduplications of the first sound are *real*, and are due to a want of synchronism in the systolic tension of the auriculo-ventricular valves of the right and left sides. 2. That they are apparent and due to an auricular immediately preceding the ventricular systole. He could not agree that the auricular systole is directly audible, but that it might cause a sound by communicating a presystolic tension to the mitral curtains under certain conditions. He adduced cardiographic tracings to prove that in certain cases of apparently reduplicated first sound the auricular systole was greatly augmented, and showed that the phenomenon might be the precursor of an undoubted presystolic murmur. As regards reduplication of the second sound, he had observed it in eleven out of thirty-seven cases of mitral stenosis. All observers are agreed that mitral constriction was the most common condition in which it was observed. He considered, from a review of the cases, that the reduplication of the second sound was often *apparent* and due to a tension communicated to the mitral curtains *early* in diastole, just as in quasi-reduplication of the first sound it was communicated *later* in diastole. The moment the ventricle becomes relaxed after its systole the blood retained in a state of tension (the pressure in the pulmonary circuit being heightened) in the auricle enters with force into the ventricle, and finding its way on the parietal side of the curtains of the mitral valve, causes them to bulge towards the ventricular cavity, and in so doing occasions the "click" of valve-tension, which, coming so soon after the second sound, closely resembles a reduplication of the latter. Although a frequent

it is not a universal explanation of this reduplication. In some cases it is very probable that the reduplication is real and due to non-simultaneous closure of the semilunar valves of the aorta and pulmonary artery. He agreed with Dr. James Barr of Liverpool, who held that over-repletion of either of the ventricles was the cause not of delayed but of anticipated sound.—Dr. GALABIN argued that reduplication was often rather apparent than real, cardiac murmurs closely approximating cardiac sounds, especially in the case of direct mitral murmur. Thus in mitral stenosis, the presystolic might be mistaken for a loud first sound and the true first sound for the second sound of the heart. He could not understand how valvular tension could occur when the valve was converted into an indurated ring. The apparent second element of a reduplicated second sound might be due to a short diastolic murmur of direct mitral character; and reduplication of the first sound apart from cardiac disease, due to the sudden tension of the ventricle after the closure of the valve.—Dr. MAHOMED believed that reduplications of the sounds were chiefly valvular in origin, although in mitral stenosis other sounds are often mistaken for reduplication of the normal cardiac sounds. He exemplified the cause of reduplication of the second sound by the recoil of two equal pieces of elastic, the one stretched to four inches, and recoiling to three inches; the other stretched to three inches, and recoiling to two inches; if stretched simultaneously they would not complete their inch of recoil simultaneously. He thus attributed the reduplication of the second sound to the asynchronous recoil of the aorta and pulmonary artery subject to abnormal variations in pressure in either one or the other. This explained the frequency of this reduplication in mitral stenosis when the pulmonary pressure was heightened. He similarly explained reduplication of the first sound, and he believed these views were identical with those advocated by the late Dr. Sibson. He did not think deduction could be drawn from cardiographic tracings, which did not signify the time of closure of the valves.—Dr. JAMES BARR (of Liverpool), in the course of his remarks, stated his belief that reduplication was due to asynchronous action of the ventricles, so that a normal doubling of the first sound occurs at the end of expiration from the increased stimulus to the right ventricle, and of the second sound at the end of inspiration from the early cessation of the right ventricular systole. In disease that ventricle which is best supplied with blood initiates the systole, although it may not complete its contraction until after the other ventricle has finished its systole; or both ventricles may begin systole together, but one may lag behind the other. He was certain there was this asynchronous contraction of ventricles (and of auricles also), each side of the heart having its own fibres.—Dr. SANSOM replied, and the Society adjourned.

OBSTETRICAL SOCIETY OF LONDON.

Congenital Dislocation of both Hips.—Rotatory Action of the Forceps.

AT the meeting on Oct. 6th, Dr. W. S. Playfair, President, in the chair—

Dr. POOLE related a case of so-called Congenital Dislocation of both Hips, and showed a little girl, aged four, with the following history:—The mother was suffering from alarming hæmorrhage, due to placenta prævia. Version was performed; the right leg brought down. The foot was fastened to a tooth-brush, and remained thus about five hours, when pains came on vigorously, and the child was delivered with ease. He did not remember whether any traction was applied to the leg. No abnormality was noticed until the child began to walk, when it was observed to limp, and the right leg was found to be in fault. The measurement from the anterior superior spine to the knee was half an inch longer than on the left side. There was considerable lordosis, with projection of the abdomen, and there was a space between the thighs in the standing position. The child had been taken to Mr. Adams, who pronounced both acetabula to be defective.—Mr. W. ADAMS said that it was a well-marked case of the so-called congenital dislocation of the hip, which, he thought, would be more accurately described as malformation of the acetabulum, with displace-

ment of the head of the femur. In this case both hips were similarly affected, and the lordosis, prominence of abdomen, large size and prominence of nates, shortness of legs as compared with trunk, and wide separation of the thighs, were characteristic. The top of the great trochanter, on each side, in the standing position, rose above the level of a horizontal line drawn from the anterior superior spine; but when the child was lying down, and a little gradual traction made from the knee, the great trochanter descended fully as low as its normal position—i.e., about an inch and a half below the level of the spine. This was demonstrated to the Society. As to causation, it had been asserted that this condition never exists except in cases of breech presentation, and is due to traction on the leg producing dislocation. In his experience of a large number of these cases, the presentation had generally been natural, and the labours easy. He believed the affection to be essentially a malformation, consisting in arrested development of the acetabulum. The production of pelvic deformity by this condition was proved by Dr. Carrochan of New York, who first called attention to the affection in 1844, and demonstrated it of a patient, of whom a life-sized model was now in the museum of St. Thomas's Hospital.—Dr. WYNN WILLIAMS concluded, from the history of the case and examination of the patient, that the ligamentum teres on both sides had been ruptured during delivery, and that the head of the bone was then drawn up against the edge of the acetabulum by muscular action.—Dr. GRAILY HEWITT thought it very desirable to ascertain whether, in the numerous cases referred to by Mr. Adams, any history could be traced of manipulating traction on the lower extremities during the labour, with a view to determine whether this had a tendency to cause such a condition.—Dr. CLEVELAND mentioned a case of a little boy malformed in this way, who had been brought over to him from Quebec, wearing an instrument for supposed spinal disease. The true nature of the case had been pointed out by Mr. Adams.—Dr. GERVIS asked Mr. Adams if spinal lordosis always accompanied these cases. If he had ever examined any after death; and if he had any experience of congenital dislocations of other articulations.—Dr. HERMAN had seen a case presumed to be one of congenital dislocation of the hip in a woman aged thirty. On the affected side the curve of the iliac crest was much flatter than on the sound side. He thought this due to the head of the femur being further back, so that it acted at less advantage in pressing inwards the anterior part of the innominate bone.

Professor STEPHENSON, of Aberdeen, read a paper "On the Rotatory Action of the Forceps." The author considered that recent modifications in forceps showed that the inventive faculty still moved in the grooves of the older and more imperfect ideas. The sole idea was how may we, with the head tight in the grip of the blades, draw with greater accuracy in a given straight line. What really is wanted is an improved form of the instrument, which will enable us to impart more readily the rotatory movements which we observe in nature. The division of the traction from the prehensile blades weakens the transmission of information by the handles to the hand of the operator; in his muscular and tactile sense should reside the true "indicating needle." The claim made for Tarnier's forceps, that they allow free movement of the head in all directions, is no more true than applies to the ordinary instrument if the operator attends to the directions which they supply. The opponents of the pendulum movement with forceps occupy good ground when they show it is contrary to the normal mechanism, and a fortuitous and risky mode of action; but they go too far when they include in their condemnation all so-called lever action. The true defence of the lever action is to throw out all that is haphazard, and give it scientific precision. The term "lever action" is objectionable; "rotatory action" is preferable. The forces of labour cannot be reduced to a single resultant, but always consist of a resultant and a couple, the former moving the head onwards, the latter imparting some movement of rotation. With forceps we have the power of producing both movements; and, as in nature they are always combined, so in art they should never be entirely separated. Hence with the onward traction made in the axis of the pelvis must always be combined such a movement of the instrument as will tend to impart to the head the rotatory movement which observation teaches us takes place at the particular stage of the mechanism.—1. *Flexion and extension.* With the head in the firm grasp of the forceps, especially if screwed up, there is a tendency to bring down both ends of the head through

an equal space, and so prevent due flexion from taking place. But, on the other hand, if the blades are applied with a diagonal grasp, the compressing power of the forceps may be made to promote flexion. But flexion or extension must chiefly be promoted by a modification of the rule of traction, which might be thus stated. Whilst the force should always be exerted with strict reference to the direction of the axis of the pelvis, the line of traction should be in a slightly curved direction; the curve passing out of the line of the axis in a direction corresponding to that of the sagittal suture, towards the side where the forehead lies, for flexion; to the side on which the occiput is, for extension. 2. The rotation of the occiput forwards might also be promoted by rotating the forceps on their axis, and bringing the handles slightly toward the side on which the occiput lies. The grasp must be light, so as to permit gliding between the blades. 3. As the head passes under the pubic arch the rule should be that whilst carrying the handles forward toward the front of the mother, a carefully applied slight rotatory action should be imparted to the forceps, so as to facilitate the change of the sagittal suture from lying oblique to approach near to that of the mesial line.—*Rotations in Narrowed Pelves.* The application of forceps tends to rotate the head from a transverse to an oblique diameter, and the frontal bone is liable to be thereby thrown on to the promontory. Hence the following rule:—When the occipital bone has descended below the level of the brim and is felt directed against the anterior wall of the pelvis, in order to clear the forehead and prevent injury to the frontal bone, the head should be rotated on a vertical axis, so as to throw the frontal bone off the promontory, and at the same time slight extension should be given to the head, to bring the forehead down to the side of the pelvis. The paper was illustrated with diagrams, which were explained by the author.—Remarks were made by the President, Dr. Roper, Dr. Edis, and Dr. Braxton Hicks.—In reply, Professor STEPHENSON said, in reference to an objection by Dr. Roper, that he doubted whether the head could rotate on a vertical axis when impacted in the brim, that all depended upon the meaning attached to the word impacted. Generally the head, though wedged in the narrow pelvis, was still movable on certain axes. Regarding occipital posterior positions, he agreed with the President and other speakers that the occiput rarely rotated forward with the ordinary mode of using the forceps. But it was possible to rotate it, and it was our duty to endeavour to do so. The "tentative" mode of employing the forceps referred to by Dr. Hicks was good, but we should not be content with it, for it might lead astray. We should endeavour to impart the rotatory movements with the precision obtained by exact knowledge.

EPIDEMIOLOGICAL SOCIETY.

THE first meeting of the present session of this Society was held on November 3rd, 1880, at University College, Gower-street, when the proceedings were opened by the President, Sir Joseph Fayrer, who delivered the inaugural address, of which the following is an abstract.

After congratulating the members of the Society on its marked prosperity, Sir JOSEPH FAYRER made a touching allusion to the losses sustained by the deaths of Dr. E. C. Seaton, Mr. Harry Leach, and Dr. Goodeve. Referring to the important work carried on by the Society during the last session, Sir Joseph Fayrer noticed especially a series of papers on Indian Fevers, and the discussion which followed them, and he expressed the hope that they might have the effect of drawing attention to the question, especially to the etiology of those forms of fever which, while presenting the phenomena of enteric fever, are considered by some to be due to general rather than to specific causes.

The subject of plague had been amply dealt with by three papers. The first was by Dr. Payne, one of the Commissioners appointed by the Government in 1879 to investigate the plague which had been prevailing on the banks of the Volga, in the province of Astrakhan, in 1878-79. This communication threw much light on the geographical distribution, history, progress, and diffusion of the disease, and on the measures taken by the Russian Government for its sup-

pression. The Commissioners considered that there was no evidence to support the theory that plague was introduced by Cossacks returning from the war in Asia, or that it was directly transferred from Resht or elsewhere on the Caspian Sea to Veltlianka, but that everything pointed to the conclusion that the disease had already gained a footing in the district (whether introduced from outside or springing up spontaneously in its soil) before the outbreak at Veltlianka. Dr. Payne remarks with regard to the possible "spontaneous origin," it appears that the same reasons which will hold to show that plague is endemic or springs up without being introduced from elsewhere, in other parts of the world, seem to apply here; actual proof of such an origin would be almost in any case unattainable, but the difficulties which beset all theories accounting for its introduction into the district certainly argue strongly in favour of such a view. With regard to the nature of the epidemic, its character and its morbid anatomy, the wide spread of the disease, with special reference to personal communication and the influence of local causes and contagion, the Commissioners had no opportunity of forming any opinion, as the disease had died out before their arrival. The information they obtained from those examined on the spot is all they had on which to form conclusions on these subjects.

An interesting summary of the German Medical Commissioner's Report was read by Mr. L. Hamilton. Dr. A. Hirsch of Berlin, whose account of the plague in Astrakhan differs from that of Drs. Payne and Colvill, describes it as a malignant, contagious disease, with all the character of Oriental plague, sometimes with buboes, sometimes without them. He attributes the outbreak to the importation of infected articles from the Asiatic seat of the Russo-Turkish war, and believes that it was not imported from Resht; neither is it indigenous to Astrakhan, where it had not appeared since 1808. Owing to faulty reports, the Russian Government did not avail itself of preventive measures until the plague had attained its maximum intensity, and was already approaching its natural termination. The report showed that considerable difference of opinion exists on the subject of the etiology and mode of propagation of the disease.

An interesting communication on Plague in India was made by Surgeon-General Dr. Francis. He pointed out its geographical distribution in Kumaon and Gurwhal, where it is known as Mahamurree, and he described the habits of the people of those districts. It has been characterised by glandular swellings, hæmorrhages, and rapid death; it is endemic, bubonic plague, caused by an animal poison which is generated by the operation of local conditions, is in no way modified by malaria, and is intensely contagious amongst the people themselves, although those who visit that country do not appear to suffer from it. The Pali plague, a disease having much the same character, appears to be closely allied to the mahamurree. Dr. Francis believed that this disease is largely due to local insanitary conditions.

Dr. Longstaffe read a paper on the Relationship existing between certain of the Zymotic Diseases, in which he argued that they should be classified under four headings—viz., the diarrhoeal group, relating to the heat of summer; the bronchitic, to the cold of winter; the scarlatinal group, and a provisional group, comprising all the other causes of death not known to be much influenced by meteorological conditions. One object of the paper was to suggest the probability that the poisons of erysipelas and puerperal fever were identical, while diphtheria and croup were also due but to one poison.

Cholera had not attracted so much attention as in former sessions, but a paper had been contributed by the late President, Dr. Murray, on this subject, showing, by an elaborate series of tables, the value of removal of troops or prisoners to other localities on the breaking out of cholera, and that the objections which had been urged against this operation on the score of expense, and the risks arising from exposure to sunstroke, had but little foundation.

The epidemic diseases of men and animals in the colony of Natal were brought under the notice of the Society by Surgeon-General Ross, C.I.E., who had recently acted as Chief Commissioner of the Stafford House Committee for the relief of the sick and wounded in the Zulu war. Mr. Ross stated that, although the climate had been proved, as a rule, healthy for human beings, it had been found most unfavourable to cattle. The disease affecting the troops in Ekowe was called typho-malarial fever, with rose-coloured spots, and affection of Peyer's glands. The diseases affecting

the lower animals were diarrhoea, pleuro-pneumonia, hæmoglobinuria, and one allied to anthrax.

The subject that has most engaged the attention of the Society has been that of certain forms of fever in India and tropical and sub-tropical climates, and several important communications on this subject had been made by men of large and varied experience. Papers by Dr. Chevers on Relapsing Fever, by Dr. Ewart on Enteric Fever, by Dr. Don on the Continued Fevers of Sub-tropical Climates, and by Dr. C. Gordon, C.B., on the Continued Fevers of India, have plainly shown that the subject still needs much investigation. The chief interest of the proceedings of the year may be said to have centred in the discussion arising out of the communications on enteric fever. It is only recently that this disease has been recognised as a cause of mortality in India, and now it appears from official reports that the death-rate from this disease among our young European soldiers is very high; the question, therefore, that has been so earnestly discussed is this: Are all the cases returned as enteric fever in which the symptoms and the post-mortem appearances are similar to those of enteric fever in this country due to the same causes? That is, are they the result of a specific poison generated in the intestines or its contents of one person and conveyed to another through the intervention of air, water, or some other medium; or are they not, in some cases, referable to what are known as climatic influences, by which is meant heat, moisture, malaria, miasmata, or to water in which these are dissolved or suspended with, perchance, the addition of other causes—ærial, telluric—of which we know nothing positively, but of whose existence as dynamic agencies we probably have indications in other epidemic diseases? As to the existence of a form of fever in India characterised by certain phenomena and pathological changes very closely if not exactly resembling those that characterise the enteric fever of Stewart, Budd, Jenner, and Murchison, there is a pretty general consensus of opinion. But on the question of causation there can be no doubt that a considerable divergence of opinion exists. It is a growing belief that the cause of some of the cases of the so-called enteric fever is to be sought in high temperature, malaria, miasmata, water contaminated by organic matter, not necessarily faecal, rather than in a specific poison generated in the intestines or in the alvine discharges after extrusion from the bowel; and perhaps in some state of body, especially in the young, that is induced by exposure to one or all of these. It cannot be disputed that the poison of the enteric contagion must be equally effective in producing fever wherever it occurs, and certainly not less so in India or the tropics than elsewhere. Few question its potency in England, though it is possible that twenty years hence, even here, this view may be somewhat modified. Some believe that the specific contagion theory will not explain the facts in all cases abroad; nor do they think that a certain train of symptoms and phenomena during life, and lesions observed after death, must necessarily be invariably due to one single cause, but rather that the bowel ulceration, diarrhoea, spots, and a certain range of febrile disturbance in the temperature, may be brought about also by other conditions such as those already referred to, and which make up what is known as climatic influence. It is difficult to resist the impression, whilst admitting enteric fever in India may originate as it does here, that other causes may be at work, and that cases of fever, which in India are not only called enteric, but present the phenomena in life and the changes after death that are characteristic of the disease in England, do occur, and not unfrequently, where it is more probable that climatic and other local conditions are the cause rather than faecal contagion, though it must be admitted that it is not possible to deny the possibility of faecal contagion where human beings have been.

The address was followed by a paper by Mr. NETTEN RADCLIFFE, who briefly described the outbreaks of cholera in Syria in 1875, Western Arabia in 1877-78, and Morocco in 1878, with a view of throwing additional light upon the origin of the two former outbreaks, and of questioning the nature of the latter outbreak. With respect to the Syrian and Western Arabia outbreaks, he endeavoured to show that it was premature to assume, as had been commonly assumed, that they had originated in the districts where they had occurred; and with regard to the Morocco outbreak, he adduced important evidence which tended to show that the disease which proved so fatal in Morocco in 1878 was not true cholera, but a choleraic affection, or rather a form of malignant dysentery, caused by the improper food which was

had recourse to by the population to assuage the pangs of hunger during the terrible famine from which the country suffered at the time.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Optic Neuritis.—Nodular Growth on Iris.—Primary Intra-ocular Hæmorrhage.

THE first ordinary meeting of this newly-constituted Society was held on October 28th, at the rooms of the Medical Society, Chandos-street, W. Bowman, Esq., F.R.S., president, in the chair. The bye-laws of the Society were read and passed; and on the motion of the president it was agreed that a committee should be formed for the purpose of communicating with the Board of Trade, with a view to remedying the possibilities of accident in the public services attributable to colour-blindness.

Dr. GOWERS exhibited two cases of Optic Neuritis. One, a girl, had been attacked by uncontrollable vomiting, succeeded by optic neuritis and paralysis of both sixth nerves. Under treatment, the neuritis had almost, and the paralysis quite disappeared. Dr. Gowers suggested local meningitis as the cause of the symptoms. The second case was that of a woman aged twenty-three, with vertical headache and a halting gait. At first the case was regarded as one of hysteria, but the vision began to fail, and double optic neuritis developed; and there was inability to move the eyeballs upwards. After eighteen months of treatment the neuritis subsided, but other symptoms remained. Dr. Gowers thought there was a lesion in the centre controlling the upward movement of the eyeballs, and suggested that the case was one of cerebellar tumour.—Dr. HUGHLINGS JACKSON pointed out how easily such cases were confounded with hysteria, and thought the diagnosis rested between meningitis and tumour.—Dr. STEPHEN MACKENZIE was inclined to believe the case one of tumour in the region of the superior vermiciform process of the cerebellum, stimulation of which had been shown by Ferrier to produce upward movement of the eyeball.—Dr. SHARKEY related a case at first taken for hysteria, where there was slight double optic neuritis, and where, after death, meningitis and cheesy tubercle in the brain and cerebellum were found.

Mr. NETTLESHIP showed a case of Nodular Growth on the Iris, following double iritis four months before. The iritis persisted on the left side, where a small yellow vascular nodule had grown. He believed it was not malignant, but felt doubtful whether an attempt should be made to excise the growth, or whether it would be better to remove the eye.—Mr. LYELL asked if there was any tubercular history. He had met with a similar growth in one eye. The patient was treated for iritis, but the growth continuing, its removal was attempted. This failed, owing to the softness of the growth, and ultimately the eyeball was excised. He thought such growths might be dealt with in their earlier stages.

A paper was read by Mr. HUTCHINSON on a case of Primary Intra-ocular Hæmorrhage, first into one eye, and subsequently into the other, with general remarks on the causes of the occurrence. The patient was a young man, who at the age of twenty-one lost his left eye by acute glaucoma, secondary to hæmorrhage into the vitreous, ciliary processes, and retina. Two years later the other eye became subject to sudden copious hæmorrhages into the vitreous, without pain or glaucomatous symptoms, the blood being quickly absorbed between each attack, but leaving finally opacity of the vitreous humour. There was no albuminuria. He was dyspeptic, habitually constipated, liable to rapid variations in local circulation, flushing, pallor, and cold feet. He was subject to epistaxis. The temporal arteries were large and tortuous, and Dr. Mahomed found his arterial tension too low. There was a strong family history of gout. Reference was made to a recent paper on the same form of disease by Mr. Eales of Birmingham. Mr. Hutchinson considered that inheritance of the diathesis took a very important share in the causation of the disease, but he did not try to explain the mode in which it operated,—whether by changes in the blood or the vascular walls, by increased arterial tension, or cardiac hypertrophy. The intra-ocular bleeding was considered as only one manifestation of a tendency to spontaneous hæmorrhage from various parts, in which a liability to inequality of circulation is the first factor,

various temporary influences acting as exciting causes. Often the male sex and the period of adolescence were among the most important; over-fatigue, indigestion, constipation, position of the head in sleep, and other influences, also took more or less share. Reference was made to some similar cases communicated to the author by Mr. Square of Plymouth.—Dr. HUGHLINGS JACKSON referred to the not unfrequent occurrence of slight ocular hæmorrhage in cases of Bright's disease and epistaxis. In one case of meningeal hæmorrhage in a young man the subject of epistaxis, a distinct clot of blood was discovered in one eye.—Mr. H. EALES (Birmingham) had been unable to obtain satisfactory evidence of gout in the cases related in his paper. In all his cases there was an unusual fulness of both veins and arteries in the other eye, and in one such supposed healthy eye he detected hæmorrhagic spots at the extreme periphery of the retina. One of his patients, since the publication of the case, had suffered from a severe attack of hæmorrhage. In another relapse of constipation had been followed by bleeding in the eye preceded by epistaxis, which had not been previously experienced for twelve months. Mr. Eales suggested that constipation might be due to deficiency of blood in the intestinal vessels, thus leading to over-distension in the systemic vessels, the veins particularly. In no case did he find the pulse over 60, and the second cardiac sound was invariably accentuated from high arterial tension.—Mr. HIGGINS asked why the hæmorrhage occurred in the eye rather than in the ear or elsewhere. In unsound glaucomatous eyes the sudden reduction of tension in the operation of iridectomy was a sufficient explanation of the intra-ocular hæmorrhage, which not unfrequently occurred, but in the cases under consideration there was no increased eye tension.—Dr. BRAILEY had found many instances of glaucoma in which the walls of the arteries of the eye were diseased. Dr. BROADBENT thought high arterial tension a sufficient cause for such effects. He had often met with cases of youths affected with headache, incapacity for work, and commonly with epistaxis; but he had not found retinal hæmorrhage in such cases, nor any gouty history. The relation between the cases read and constipation was to be explained by high arterial tension, and he advocated purging as a rational procedure.—Mr. BRUDENELL CARTER questioned the advisability of referring such cases to a "gouty" diathesis.—Mr. HENRY POWER referred to the occurrence of similar hæmorrhages in pregnant women as a proof of the cause being alteration in vascular tension.—Mr. HUTCHINSON, in reply, said that he was surprised at the evidence of low tension in his case, but suggested that the tension might not be the same in all parts of the body. He argued that varying degrees of tension in the eyeball might influence hæmorrhage into it. "Gout" was a term indicative of an understood and distinctive disease, and in the case read there was ample reason for assuming a gouty tendency.

The Society then adjourned.

Reviews and Notices of Books.

Atlas of Histology. By E. KLEIN, F.R.S., and E. NOBLE SMITH. Part 12. London: Smith, Elder, & Co. 1880.

THIS part, which is unusually large, opens with an account of the structure of the skin, and a particular description is given of the stratum Malpighii, and especially of the nuclei of the cells of this layer. It is shown that in the deeper cells the nucleus consists of a honeycombed reticulum without any nucleolus or limiting membrane; that in others the fibrils of the nucleus become arranged as a rosette; then they change into a star, when they receive the name of *monaster*, and later on into a double star, or *dyaster*. The cell then divides through a line separating the two asters. Each daughter star changes into a convolution, and this again forms a well-defined nucleus. The superficial layers of the stratum Malpighii are differentiated, and described as the stratum of granular cells of Langerhans, or stratum granulosum of Unna. This layer colours a deep purplish blue with hæmatoxylin. The granules are more or less discoid in form, and therefore appear rodlike in the profile view, and are a transition form between protoplasm and

keratin. The stratum Malpighii is firmly adherent to the surface of the corium by an albuminous cement, into which the branched lymph spaces and the connective-tissue corpuscles penetrate. The authors then give in succession the structure of the papillæ and the sweat-glands. It is stated that the human anus is surrounded by an elliptical zone presenting a number of large coiled gland-tubes, the circum-anal glands of A. Gay. Each of these, on minute examination, proves to be a huge sweat-gland. A very full account of the different structures of the hair-follicles, hair and sebaceous glands, succeeds. Each hair-follicle consists of the vascular hair-sac, the papilla, and the outer root sheath. The hair-sac is composed of an outer longitudinal and an inner transverse coat, and is continuous with the papillary layer of the corium and with the connective tissue of the septa which penetrate between the lobules of the adipose tissue. The inner surface of the transverse layer is lined with relatively short and broad unstriped muscle-cells. The hair-sac and papilla are separated from the next following or inner layer of the hair-follicle by a glassy hyaline basement membrane, which is a direct continuation of the basement membrane of the corium. It is divided from the outer layer of the outer root sheath. The outer root sheath is continuous with the stratum Malpighii of the epidermis. The root of the hair consists of the substance of the hair, the cuticle, and the hair sheath, or the inner root sheath. The central cells at the apex of the bulb become the axial cells of the hair, and those more laterally placed become the elongated cells of the cortex of the hair, or the cuticle of the hair. The next outer layer of polyhedral cells of the bulb is continuous with the membrane separating the cuticle of the hair from Huxley's layer. The one or two layers of cells next following pass into the layer of Huxley, and finally the outermost layer or two pass into the layer of Henle. All these parts are very clearly delineated both in transverse and in longitudinal sections in Plates xli. and xlii. The remainder of the section is occupied with a description of the sebaceous glands, the nails, and the lymphatics of the skin. Chapter 34 is devoted to the consideration of the eyelids, the conjunctiva, and the lacrymal glands; Chapter 35 to the cornea and sclerotic; Chapter 36 to the iris, ciliary processes, and choroid; Chapter 37 to the lens and vitreous body, and Chapter 38 to the retina. Plates xliii. and xliv. contain the drawings illustrating the microscopic anatomy of these parts.

The description of the retina does not add materially to what is already known, but rather consists of a carefully-made compilation of all recent work; even in this way, however, it will prove very serviceable to workers with the microscope.

Malaria: its Cause and its Effects. By E. G. RUSSELL, M.B., B.Sc. Lond.; Surgeon, Bengal Medical Service; Civil Surgeon, Kamrup, Assam. London and Calcutta: W. Thacker, Spink, and Co. 1880.

ENGLISH practitioners can no longer afford to disregard the study of tropical diseases, especially those of a chronic nature. Our colonial possessions within the tropics are now so enormous, and the means of transit from them so rapid (shortened as it has been by the opening of the Suez Canal), that the number of persons invaliding home is annually on the increase. Thus cases of malaria and its sequelæ, enlarged liver and spleen, and chronic dysentery, are much more frequently brought under the notice of the English physician than was the case thirty or forty years ago, when the tedious voyage round the Cape either killed or benefited the invalid. At the same time, tropical diseases remain a *terra incognita* to most of us. In the present volume Dr. Russell discusses most exhaustively the subject of malaria and its effects, and the work should be read by all who are liable to be called upon to treat the conditions to which it gives rise. The chapter which describes the malarial lesions of the stomach and

liver will perhaps be read with the most interest by the English practitioner. Dr. Russell offers a useful hint not to mistake the severe dyspepsia and gastric irritability associated with pale diarrhœa arising from too constant and prolonged a residence in malarious regions for hepatic disease induced by "free living"—a caution the more needed since, we fear, all dyspeptic troubles occurring in old Indians are apt to be regarded as due "to liver" provoked by unlimited brandy pawnee, hot curries, and tropical suns.

Dr. Russell ably discusses the relationship between ague and typhoid—a question that has been raised by Sir Joseph Fayer. Dr. Russell observes that the pyrexia of true non-malarial typhoid often so closely resembles that of true malarial remittents that in India the diagnosis between these two diseases is frequently extremely difficult, and must be decided almost entirely by other distinctions than types of pyrexia. Indeed, so great frequently is the difficulty of accurately distinguishing the one disease from the other, that there are still physicians who consider there are sufficient grounds for denying the existence or occurrence of typhoid in India. Dr. Russell believes there frequently occur epidemics in which the fever partakes both of the nature of typhoid and true malarial intermittent and remittent fever. He supports the view of the existence of a typho-malarial fever by quotations from numerous authorities, but omits the weight given to it by Lancisci, who observed that on opening the bodies of certain patients who had died of semi-tertiary fever lesions were found in the intestines which had perforated all the coats. The second part of the volume is devoted to an analysis of fifty cases of injury of the spleen. These injuries from the frequency of their occurrence, and the importance of their medico-legal bearings, are of peculiar interest to the medical practitioner in India, but their consideration need not detain us at present. We therefore leave Dr. Russell's volume, commending it to the notice of our readers as a book full of facts and of clinical research, and which must be considered as an authority on the subject of Malaria.

Practical Histology and Pathology. By HENEAGE GIBBES, M.B. H. K. Lewis, 136, Gower-street, W.C. 1880.

THIS is a small book written by a practical man, evidently well acquainted with his subject, and will be found of real service to those who wish to learn how to prepare good preparations for microscopical examination. The appliances required—microscope, knives, reagents, &c.—are first briefly described, and then the manner of obtaining all the tissues necessary for a thorough examination of the structures found in the human body, with directions for hardening them, are given. The chapter on staining is in some respects the most valuable, for Dr. Gibbes has made this subject a special study, and has obtained new and excellent results from using two and even three dyes at once; the methods by which others may be as successful are here plainly given. Two chapters are devoted to special directions for demonstrating the individual histological and pathological structures. The book is small, the directions concise and clear, but we believe the student will find in it all the help he can hope to derive from such a source, in a study where successful results can only be obtained by patience and perseverance.

The Physician's and Surgeon's Visiting List, Diary, Almanack, and Book of Engagements for 1881.

THIS well-known "List" needs no praise. It is very compact and neat, and the various tables bound up with it make it most useful to the practitioner. Two of these call for special notice—one giving the days of incubation, &c., of the various fevers; the other, the corresponding degrees on the thermometric scales of different thermometers.

New Inventions.

NEW CARBOLIC HAND SPRAY-PRODUCER.

THIS is a modification of Lister's hand spray, suggested by Mr. Golding Bird. The size of the bottle usually supplied with the apparatus is often insufficient, whilst the holding of a larger bottle in the hand during a long operation is obviously inconvenient, especially if hot water be employed. These objections are overcome by supplying a bottle of four or more ounces' capacity (from which proceeds a specially-constructed flexible tube nearly a yard long and terminated by the spray-nozzle) carried at the side in a leather pocket by means of a strap slung across the shoulder.

In this way boiling water may be used, and the temperature may be thereby kept up for a considerable length of time, so that the spray resembles that from the steam spray. The simple apparatus is portable, and will be found especially serviceable in operations of short duration, dressings, and all cases where the steam spray is inconvenient or not available. The long flexible tube allows of the spray being turned in any direction, and the bellows can be readily changed from hand to hand, thereby avoiding fatigue. The apparatus is made by Millikin and Down, 3, St. Thomas's-street, London, S.E.

THE "CROWN JEWEL" STOVE.

Now that the question of London smoke is so much to the fore, every contrivance for affording heat without smoke is sure to command attention, and we have great pleasure in giving a short space to a description of a stove for burning anthracite or coke, made at the Detroit Stove Works, U.S.A., and on sale in London at the house of the agent, Mr. Harry Hunt, 117, Newington-green-road, N. It is intended for the heating of halls, passages, and public buildings. The form of the stove is rather elegant than otherwise, and it has the great advantage of allowing the fire to be visible through tall windows, so that it is thoroughly cheerful and pleasant to look at. It requires very little attention, needing only to be filled up with anthracite about twice in the twenty-four hours, so that, in America, a stove lighted at the beginning of winter is never allowed to go out; and the risk of its going out is lessened by the fact that the fire can be seen as well as felt. By means of dampers the rate of combustion and the amount of heat given off can be regulated to a nicety. There is no smoke, and consequently the flues never need cleaning; there is no escape of fumes when fuel has to be supplied; and by the consumption of

37 lb. of anthracite (value 4*d.*) per diem the manufacturers guarantee that the temperature of a moderate-sized house can be maintained at 25° F. above that of the outside air.

The stove is not expensive; and from what we saw of it in action at the late Food Exhibition in the Agricultural Hall, we can very strongly recommend it to the consideration of our readers.

"VEGETABLE-WOOL" GOODS.

MESSRS. WELCH, MARGETSON, & Co. have submitted specimens of articles of underclothing, jerseys, &c., made of Lairitz's pine-wool material. The fabric, which is composed of fibre prepared from the leaves of the pinaster, or black pine, is soft and of fine texture. In cases where the pine is deemed likely to prove helpful these articles will be found admirably adapted for use, and pleasant for wear. From a sanitary point of view, they certainly appear to possess physical properties superior to those of animal wool.

MEDICINE BOTTLE BAGS.

THESE paper bags are meant to save the dispenser the trouble of cutting up paper for wrapping medicine bottles in, and of stringing and waxing the parcel. They are made for bottles of all sizes, and seem a practical contribution to prompt and neat dispensing. They are the invention of Mr. George Jones, of Evans and Jones, Leadenhall-street.

PHARMACOLOGY AND THERAPEUTICS.

RESORCIN: A NEW ANTISEPTIC.

OBSERVATIONS have been lately made in Germany on the antiseptic and antipyretic action of certain members of the dihydroxybenzol group, *brenzcatechin*, *hydrochinon*, and *resorcin*. The latter has received most attention. It is a substance obtained from certain resins, especially from *galbanum*, and has been recommended as an antiseptic by Dr. Andeer of Warzburg. Its formula is $C_6H_4(H_2O)$, and it is readily soluble in most liquids, including bisulphide of carbon and chloroform, and can be employed in all modes of pharmaceutical preparation. It has a peculiar odour, somewhat like carbolic acid, and has a bitter-sweetish taste. It coagulates albumen readily, and thus is suitable for use as a caustic. The similarity between the chemical constitution of *resorcin* and carbolic acid led Andeer to make experiments which showed that it possesses considerable power of arresting decomposition and fermentation. A one per cent. solution will retard fermentation, and a stronger solution will arrest it altogether, and destroy the movements of infusoria and low organisms. Applied in different forms and strength to the uninjured skin of men and mammalia, it causes neither discoloration nor any profound irritation or evidence of paralysis. Injections of concentrated solutions into the muscles cause toxic effects. Application to the moist lips causes a white eschar. Administration by the mouth causes, if long continued, symptoms of poisoning, which are readily allayed by albuminate of iron and red wine. With the most intense toxic symptoms in men—convulsions, rigidity, &c.,—elevation of temperature was never found. Analytical observations show that *resorcin* causes a considerable increase in the secretion of sulphur, and thus it appears to cause a breaking up of sulphur compounds in the body, and with this is an increase in the nitrogenous excreta.

Dr. Andeer formulates the following conclusions regarding the pharmacological action of *resorcin*. It is a good antiseptic for the prevention of all abnormal fermentation processes which are associated with putrefaction. In one per cent. solution it prevents all putrefaction in such substances as pancreas, blood, and urine, which usually readily

undergo decomposition. Such liquids keep their natural odour. A solution of the same strength arrests putrefaction when this has already commenced, either through direct destruction of the excitants of putrefaction, or by coagulation of the liquids which serve as pabulum to them. In artificially produced septic processes a solution of the same strength has an antiseptic action as powerful as that of carbolic acid, without being absorbed into the blood-current of the animal to the same deleterious degree as carbolic and pyrogallic acids. Artificial, punctured, and incised wounds always heal by first intention, if treated with this solution.

Wounds of the cornea, conjunctiva, gums, or other mucous membranes, which have been irritated and infected with micro-organisms, heal rapidly if they have been cauterised with resorcin, and its application is equally efficacious in the treatment of subcutaneous abscesses and erysipelas. A 1 or 2 per cent. solution has no more action on the uninjured skin than plain water, and causes no eruption. It is thus well suited for use in the form of spray in surgical practice. Andeer recommends it also in abnormal processes of fermentation connected with the mucous membranes, in septic processes of the buccal cavity, "mycosal" affections of the stomach, intestine, and bladder, for the cauterisation of catarrhal, tubercular, and syphilitic ulceration, and in diphtheritic affections. For internal use, the dose recommended is a teaspoonful of a solution of one to five grammes, in one hundred parts of water. Alcohol, glycerine, and syrup of orange-peel are convenient liquid vehicles.

Lichtheim has investigated the properties of the same substance as an antipyretic. Two or three grammes in solution caused, in a few minutes, giddiness and tinnitus, flushing of the face, acceleration of pulse and respiration. In ten or fifteen minutes the patient began to perspire freely. With the sweating the primary stimulant effect rapidly subsided; the pyrexia also subsided. An hour after the administration of the resorcin the pulse and temperature had fallen to the normal, and the diaphoresis had ceased. The depression of temperature amounted in some individuals to 3° C., and the fall in the pulse-rate to one-third. The antipyretic effect, however, was found to be slighter the greater the tendency of the febrile disease to spontaneous remission. In pneumonia and erysipelas the fall of temperature was slighter than in typhoid fever, and severe cases of the latter were influenced less than slighter cases. The antipyretic effect was usually proportioned to the diaphoretic action, and was of briefer duration than in the case of salicylic acid and quinine; in about three hours it again rose rapidly, often with a rigor. The dose can, however, be repeated without injury to the patient. As a rule, little excitement was caused by it, but occasionally it produced transient delirium and tremor. The urine, after its administration, assumes a dark brownish-black colour on exposure to the air; and on the application of hydrochloric acid and heat, a dark-brown precipitate is produced, probably an oxidation product. The pulse, under its influence, becomes less frequent, and diuresis becomes slighter. It has no apparent specific effect in pneumonia, erysipelas, or typhoid, and in acute rheumatism it has no influence on the joint affection. In intermittent fever, however, it has an apparently specific action, comparable to quinine.

HYDROCHINON.

Another member of this group, hydrochinon, has been investigated by Brieger, who finds that it possesses a stronger antipyretic action than resorcin; '2 gramme depresses the temperature half a degree Centigrade. Larger doses, up to a gramme, cause symptoms of excitement similar to those caused by resorcin. Like it, also, the effect on the temperature in disease is very brief. It has no local irritating effect, and, injected under the skin, produces no more disturbance than water.

SALICYLATE OF SODA POISONING.

The disturbance of the special senses which results from salicylate of soda is usually believed to be confined to the ear. Slight disturbance of sight has, however, been recorded by several observers, and in a case recorded by Gatti complete transient amaurosis was observed. The patient was a girl, sixteen years of age, suffering from acute rheumatism, and had taken, in the course of ten hours, two drachms of the drug. Three hours after the last dose she awoke from sleep totally blind, with considerable mydriasis, but no disturbance of sensibility of the cornea or of the conjunctiva. There was no visible change in the fundus oculi. There was

considerable deafness. The urine did not present the salicylate reaction. Ten hours later, on waking from a sound sleep, sight had perfectly returned. Mydriasis and deafness continued for some time longer. Both urine and saliva continued free from the salicylate reaction, which seems to show that the drug was retained within the system instead of being eliminated.

ACONITIN.

Aconitin is a remedy which practitioners in this country have always hesitated to give internally on account of its highly poisonous properties and the uncertainty of its purity. The difficulty in dispensing so powerful a drug, especially in the form of pills, increases the liability to accidents. This hesitation will not be lessened by cases reported recently at Bordeaux by Dr. Armaignac, and from Germany. A patient suffered from violent pains in an eye the seat of cataract. Pills containing each a quarter of a milligramme of aconitin ($\frac{1}{40}$ gr.) were ordered, four to be taken daily. On the first day no special influence was observed. On the second, vomiting, giddiness, and prostration occurred, and the patient was found in a state of syncope, cold, with a cadaveric aspect, and a pulse of 44. Under the use of stimulants, and subcutaneous injections of sulphuric ether, the patient gradually recovered. In Germany three cases of poisoning by French aconitin are reported by Busscher. The doses which occasioned toxic symptoms were respectively four-tenths of a milligramme (about $\frac{1}{100}$ gr.), $\frac{1}{2}$ milligrammes (about $\frac{1}{200}$ gr.), and 4 milligrammes (about $\frac{1}{25}$ gr.). In the last case death occurred. Convulsive symptoms occurred first, and were followed by narcosis. The dose had been ordered by a practitioner under the impression that the French and German aconitia were similar in strength.

If aconitin is given internally at all, it is certainly unadvisable to use any form except that which is crystallised. The term was formerly, and still often is, an amorphous alkaloidal substance, which contains, in addition to the crystallisable aconitin, variable quantities of much less active basis. Another cause for the uncertain strength of this preparation arose from the readiness with which the crystallisable aconitin is decomposed in the preparation. Various chemical reagents split it up into benzoic acid and an almost inert base (aconine). Hence a demand for the pure crystallised alkaloid has sprung up, which is, according to the *Chemists' Journal*, very much in excess of the supply. The demand comes especially from America. Pure crystallised aconitin can only be prepared from *Aconitum napellus*, and this plant is not grown in America in sufficient quantities to enable manufacturers there to supply the local demand, and in Europe it is prepared only on a very small scale.

HYOSCYAMIN.

Unpleasant toxic symptoms after the use of moderate doses of hyoscyamin have been reported by M. Empis. The patient was suffering from paralysis agitans, and a twelfth of a grain of hyoscyamin caused symptoms of intoxication, while a second similar dose given on the following day caused nausea, violent delirium, tetanic spasms, dyspnoea, dysphagia, and strangury. The accidents subsided in the course of three or four hours. It should be remembered that active principles which cannot be crystallised are often of variable potency, according to the mode of preparation and the part of the plant from which they are derived, and they should therefore be used with caution.

THE ALKALOIDS OF HEMLOCK.

Hemlock contains, according to the observations of several investigators, two active principles: conia, having a paralyzing influence on the central nervous system; and another agent, acting like curara. A salt of hydrobromic acid, obtained from hemlock, has an action similar to conia; and Prevost of Geneva has asserted that the paralyzing effect of this salt is due to an action on the motor nerves—i.e., that it also acts like curara. This conclusion has led M. Boche-fontaine to make a fresh series of investigations on the action of conia. He finds that it is readily absorbed from the stomach, relieving local pain, and also inducing sleep. It abolishes reflex action and sensibility. After its administration, stimulation of the central end of a divided sciatic nerve causes neither pain nor reflex movements, while muscular contraction is still produced by stimulation of the peripheral portion of the nerve. These effects are diametrically opposite to those caused by curara; and the difference of action is further brought out by a comparative experiment on two frogs, which shows that conia lessens or abolishes

the physiological properties of the nerve-centres, before acting, like curara, on what Vulpian has called the "neuromuscular junction." In both dog and frog a sufficient quantity abolishes all nervous excitability, but this dose is always fatal.

Regarding the crystallisable salts of hydrobromic acid which can be obtained from hemlock, M. Bochefontaine finds that they may be divided into two groups. One is yellowish, is very toxic, and has the typical action of conia. The other, colourless, is less powerful, and has a different action. It has the same effect upon frogs as curara, but, instead of recovering as they do after a small dose of curara, they do not recover from such a dose of the salt as causes a similar effect on motor excitability. Even a dose insufficient to abolish voluntary movements causes death at the end of two or three days. Successive crystallisation of these salts tends to eliminate that which acts on the central nervous system, and to isolate the curarising principle.

THE ACTION OF PILOCARPIN ON THE PUPIL.

The mode of action of drugs which affect the pupil has always been a somewhat obscure subject, and an investigation into the mechanism by which pilocarpin contracts the pupil, by Drs. Laborde and Fitzgerald, is of considerable interest. Five milligrammes of the hydrochlorate of pilocarpin injected beneath the skin of an animal determines, in five minutes, not merely general diaphoresis, but also a strong contraction of the pupil, and this even though the third nerve has been previously divided, so that the central influence on the sphincter is at an end. The drug must therefore act by stimulating locally the fibres of the sphincter, or it must paralyse the sympathetic innervation of the dilating fibres. The local action, although intelligible when the drug is applied locally, is scarcely conceivable when it is introduced into the general system. The action on the sympathetic seems the more probable. If the third nerve has not been divided, and the action of the drug is closely watched, the first effect is a fixation of the pupil in a state rather of mydriasis than of myosis, apparently due to a simultaneous paralysis of both muscles; then the sphincter gets the ascendancy, and the pupil slowly contracts. That such a double action really takes place is shown by the effect of the drug when the sympathetic has been divided, the third nerve being intact. Then, the action of pilocarpin is to slightly dilate, not to contract, the pupil. Thus there is reason to believe that the drug acts as a paralyzing agent upon both sets of nerves to the iris, and the myosis is due to its action upon the third nerve being less than its action on the sympathetic, or to the fact that, when both are paralysed, the tonic force of the sphincter is the more powerful. It may be noted, however, that Albertoni, and recently Harnack and Meyer, have come to a different conclusion. Finding that when the pupil is strongly contracted by pilocarpin, irritation of the cervical sympathetic still gives rise to considerable dilatation, they believe that pilocarpin causes contraction by stimulating the third nerve. The fact, however, is quite reconcileable with the observations of Laborde and Fitzgerald, since the paralyzing action which they assume may be on the central connexion of the nerves, and then stimulation of the trunk would still cause contraction of the dilating fibres.

JABORIN.

In connexion with the slight mydriatic action which Laborde and Fitzgerald observed, it may be remarked that jaborandi has been found by Drs. Harnack and Meyer to contain an alkaloid, which they have termed jaborin, which dilates the pupil and has an action on the heart, the salivary glands, the intestines, and the central nervous system, exactly like atropin, and which is found also, like it, to antagonise the action of muscarin. These authors point out that many commercial preparations of pilocarpin contain also jaborin, and the presence of this substance may explain the mydriatic effect of pilocarpin observed by Laborde and Fitzgerald, at the commencement of its action and after the sympathetic had been divided. It is evident that to furnish conclusive evidence that pilocarpin acts on both sets of nerves, their experiments must be repeated with a preparation of pilocarpin from which all jaborin has been removed. It is possible that jaborin may turn out to be actually identical with atropin or with hyoscyamin. Professor Ladenburg of Kiel has lately asserted that there are only two mydriatic alkaloids, atropin and hyoscyamin—daturin, duboisin, and hyoscyamin being not merely closely related but actually identical.

LEPROSY.

To the Editor of THE LANCET.

SIR,—Cases of true leprosy are not so rarely seen in this country as it is generally supposed. We have met with them from time to time in the seaport towns on the north-east coast, having been brought over from Scandinavia; and, indeed, we have reason to think that they are occasionally overlooked. Although there can be no question as to the nature of Mr. Startin's case, still I think he is somewhat in error when he states (apparently on good authority) that "there could not be a more typical case." I have seen and carefully noted the lepers in the "Spedalskshed" hospitals of Bergen, and am of opinion that this case, taken as a type, would not have afforded the best representation of a leper, as it appears to have exhibited somewhat sparingly the distinguishing features of both the tubercular and anæsthetic varieties. A well-marked example of the tubercular form of the disease, besides the tumefaction of the corion, deposits of pigment, &c., presents the characteristic tubercles, hard or soft, as the case may be, on the nose, on ears, eyelids, lips, or conjunctivæ, and as far as this special class (which is by far the larger in Norway) is concerned, a case is certainly not typical without them. Nor is Mr. Startin's case a very good specimen of the anæsthetic variety, inasmuch as some of its distinguishing signs—viz., white (not discoloured), shining patches and areas, pronounced anæmia, mental torpor, and lardaceous deposits in internal organs, seem to have been absent. Notwithstanding Mr. Startin's opinion to the contrary, there is reason to believe, as I was assured by Drs. Danielsen and Moon in 1875, that leprosy is contagious during the acute or exanthematous period, although it is certainly not so in the later stages. I confess it is never contracted by the nurses or attendants in the hospitals in Bergen, but this is accounted for by the fact that the acute stage is past when the patients are admitted.

In Norway leprosy occurs pre-eminently amongst the dirtiest of the poor, ill-housed, ill-fed, and ill-clothed inhabitants, and although stale fish is a staple article of food with this class, there is no evidence whatever to prove that its consumption operates more than any other predisposing cause in the production of "spedalskshed." Dr. Manson, I read a few years ago, received some reward from the Chinese Government for the discovery that leprosy was caused through the introduction of a poison into the blood by the bite of the mosquito, and although little has been heard of this discovery since, the idea seems to receive support from many facts, and explains the curious occurrence of that dreadful malady in the arctic regions, where the mosquito abounds. We know little else that is new concerning the etiology of leprosy, since the committee of the Royal College of Physicians published their report in 1867, I think it was, but it is very desirable that its occasional presence in our midst should not be forgotten, in order that it may be at once recognised and not confounded with scrofula, syphilis, or other diseases which it often closely resembles. Mr. Startin's case is, in my opinion, well worthy of record.

I am, Sir, yours faithfully,

Hackney, Nov. 1st, 1880

SAM. WILSON, M.R.C.S., &c.

To the Editor of THE LANCET.

SIR,—The following will bear out Mr. Startin's statement in the case of "True Eastern Leprosy," published in THE LANCET of Oct. 30th—viz., that eating of bad fish does not produce leprosy:—

In 1875, when civil surgeon of Pooree, Orissa, I was investigating the theory of fish diet producing leprosy, and directed my attention to the Telooagoos, a class of fishermen who live in an isolated village of their own on the sea-coast. They number in all, I should say, about one thousand; their diet consists almost exclusively of fish (with vegetables, when procurable), and at the time I made my inquiries I failed to detect a single case of leprosy in the whole village, although leprosy is common enough in the city of Pooree, especially amongst the pilgrims. I may further add, that the Telooagoos were very partial to a form of dried decomposed fish, dried by exposure to sun and air.

I am, Sir, yours faithfully,

Manchester, Nov. 3rd, 1880.

H. W. HILL, M.B.,
Surgeon, Indian Army.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 13, 1880.

THE commencement of a new session at the medical schools, and the announcement of an organisation designed to bring the Registrars of hospitals into close and practical relations in their common work, offer a fitting opportunity for the suggestion of one or two considerations of great moment to the progress of the healing art. Hospital work is continuous, but it is formally utilised for scientific purposes both at the schools and in the Societies chiefly during the season on which we are entering. Will those of our readers who are responsible for collecting the figures and facts by which the practice of medicine and surgery throughout the country is governed bear in mind how meagre and vague these data generally are when they come to be viewed in the light of the exact science of statistics? Notwithstanding the pains and carefulness of the great majority of observers, the records at command for the purposes of the statistician are comparatively more scanty than those furnished by the recognised workers in any other branch of science. This is in part, doubtless, due to the fact that the hospital services provide, after all, only a very limited field of observation, but it must not be forgotten that professional work generally takes its tone from, and in great measure follows the lead of, the hospitals. If a better system of reporting were adopted at the teaching centres, the improvement would, we may hope, speedily spread to the outermost circles.

What science—and therefore art—needs is a return under a common system of notation for the record of details of *all* cases falling under observation. Clinicians seem to forget that no “average” or “mean” can be accepted, more particularly when worked from a small number of facts, until it has been corrected by collation with the great mass of comparable facts to which it is naturally related. For example, the rates of mortality in particular diseases require to be corrected by the rate of mortality for disease as a whole, and this is especially necessary when the numbers forming the base of the calculation are small. So is it with each member of the series of medical facts and phenomena. It is impossible to form a true estimate of the comparative excellence of any two methods of treatment, or to ascertain the real significance of any symptom, unless the materials for the judgment to be formed have been collected and compiled in accordance with the known and inviolable laws of statistics. At present only selected cases are reported—or, as it would seem, even recorded in a *clinical* sense—at the hospitals. This is as though only the death of wealthy or poor, or tall or short, persons, should be returned to form the bases of a death-rate; and, to complete the absurdity, the *principal* factor, age, is either omitted or disregarded! The utmost that can be deduced from the reports of series of cases or the tables appended to hospital annuals thus compiled, is the fact—in so far as it is a fact—that a certain proportion of the cases treated in a particular institu-

tion, or in a certain way, by some individual practitioner, has resulted as the report shows; and under precisely similar circumstances the experience *may* be repeated. In order to make the returns supplied to the profession of any practical value, it would be necessary to work out the life status and expectancy of each hospital population and of the populations from which its individual members are taken. What, for instance, is the worth of the simple fact that a particular percentage of cases treated in a certain way, either medically or surgically, died or recovered, unless we are furnished with the means of judging how much of the mortality or recovery noted was due to conditions, such as the age and class of the population to which they originally belonged, and the vital expectancy of the hospital population into which they were imported? It is startling to discover the utterly valueless character of the great bulk of the returns commonly furnished. There ought to be a trained statistical officer attached to each of the hospitals, whose duty it should be to work out and correct the data furnished for general remark. If the existing Registrars are so qualified, and can be so brought together by the new Society as to work in harmony, great good will certainly result from the movement.

Meanwhile, the mere creation of a special clinical registry, constituted by an Association of Medical Registrars, will not place the returns on a satisfactory footing unless the general facts needful to make each special series complete are collected. It will be well if any recent or concurrent event should direct the attention of the Medical Faculties of hospitals to the indispensable, and, it would have seemed, self-evident, obligation under which they lie to organise and maintain a perfect system of clinical reporting. Notes of every case should be taken officially, and for the Faculty, with a view to medico-statistical purposes. The waste of priceless material which has been tolerated is astonishing, when we come to look at it in the aggregate. Questions relating to ages, heights, vital capacities, weights, and even the presence or absence of particular symptoms in certain morbid states, may at any moment crop up, and a general return may be essential to an accurate opinion; but although the data have been, so to say, thrown at our feet for years past, we have not taken the trouble to gather them. If medical men, who need the aid of statistics more, perhaps, than any other class of active workers, were better versed in the laws which govern the logic of figures, this system, or rather want of system, would not be longer tolerated.

THE progress of the cinchona cultivation in India has a very practical interest for the inhabitants of this and other countries. Large quantities of cinchona alkaloid are annually needed in India in the treatment of the malarial fevers which infest many parts, and the growth of enough bark in the country to supply Indian needs will afford appreciable relief to the too great demand on what is produced by other countries. Still greater will be the advantage if, as seems likely, cinchona bark can be grown in sufficient quantity to permit of its export.

The annual reports of the superintendent of the Government cinchona cultivation in Bengal, and of the Government quinologist, for the year 1879-80, have just been published, and the facts which they describe are of a very

encouraging character. Both are from the pen of Dr. G. KING, M.B., who has during the year fulfilled the duties of both posts. About three-quarters of a million of young trees were planted, and the efforts to propagate the *C. calisaya* and hybrid varieties have at last begun to bear fruit. The greater success of the Dutch in growing the former in Java led to a visit to those plantations by Dr. KING. He found that the results were largely due to the superiority in the volcanic soil and equatorial climate of Java. Dr. KING gained, however, some practical information on several points, one of which is the advantage of the Dutch method of shaving the bark from living trees, instead of uprooting them altogether. The entire produce of the plantations for the year was 361,590 lb. of dry bark, as against 261,659 lb. in 1878-79—a very satisfactory increase. Of last year's produce, 29,520 lb. were yellow, and the rest red bark. It is proposed to take 350,000 lb. of red bark as the crop of next year, but should it be found, as the season advances, that more is likely to be wanted, it is said that it will not be difficult to increase the quantity to 400,000 lb.

During the year four plants were received from Sir J. D. HOOKER of the valuable species of cinchona which yields the bark known in commerce as Carthagena or Columbian. Although long known in the market by its produce, this species has never been brought into cultivation in India. Seeds were brought from Columbia by Mr. R. CROSS, who was commissioned by the Secretary of State to go to South America to procure them. The seeds were sown at Kew, and the resulting plants sent to India. They are growing well, and there is every prospect that they will be successfully propagated.

The greater part of the bark is employed in the preparation of the "Cinchona febrifuge," an extract consisting of the more or less impure alkaloids. No less than 9434 lb. of this febrifuge were prepared, as against 7007 lb. in the previous year. The question of manufacturing a superior drug has been under consideration by a Special Committee appointed by the Government in 1877. After discussing the question of how far the febrifuge could be improved by excluding its amorphous constituents, the Committee recommended for trial a mixture of four parts of sulphate of quinine, eight of sulphate of cinchonidine, and nine of sulphate of cinchonine. The result of the trial showed that the antiperiodic properties of the febrifuge are not diminished by excluding the amorphous alkaloids, while the triple sulphate has the advantage of creating less nausea and gastric disturbance than the ordinary febrifuge. At the same time the Committee considered that the proportion of cases in which the febrifuge had been found to create nausea was so small, while its efficacy in the treatment of fevers has been so unmistakably established, that the remedial advantages to be gained by substituting for it a finer preparation are not sufficient to warrant any great increase of cost. They recommend, however, that the experiment should be made of erecting a small factory in which the preparation of the pure alkaloids of *Cinchona succirubra* could be carried on, so that the cost of producing the triple sulphate on a large scale can be ascertained. This proposal is now under consideration by the Government of India. The sale of the febrifuge to the public has increased considerably, a sure proof that it is rising in general

estimation; 2757 lb.—more than one-quarter of the total produced—was thus sold. The substitution of this febrifuge for the imported quinine has effected a saving of four lakhs of rupees, and the total saving since the factory commenced working has been greater than all the plantations have cost since they were opened.

The Calisaya bark is less suitable for the manufacture of the febrifuge than the red bark, and a surplus stock which had accumulated has been sent to Europe during the year. There is a prospect, however, that quinine may be made on the spot from this bark. The superintendent of the factory, Mr. GAMMIE, who is strongly recommended by Dr. KING, has devoted much time to an endeavour to prepare pure sulphate of quinine. His efforts have been so far successful that he has produced from both *Succirubra* and *Calisaya* barks quinine which is indistinguishable in appearance from that sold by the best European makers.

It cannot but be a matter of deep regret to all who take an interest in our Navy—and what Englishman does not?—that the Government have as yet given no indication of their intentions with regard to the Medical Department of that branch of the public service. The lamentable condition of unpopularity into which it has been permitted to fall has been only too well shown by the want of candidates for admission into it. When the Admiralty advertise twice, or sometimes thrice, a year for candidates, they are unable to obtain more than five, while the Army gets above eighty, and the Indian Service usually more than twice as many as they have vacancies to fill. The advice given to the students at the medical schools is, whatever you do, avoid the Navy, and this will continue to be the case until steps are taken to place the department more on a footing with that of the sister service, and to remove those well recognised grievances which afford justifiable grounds for this otherwise unpatriotic course. The Government has, since coming into office, had sufficient time to have inquired into this state of matters, and to have ascertained the extent of the evil and the nature of the remedies which are required, but yet the only resolution at which they appear to have arrived is that the question of the re-organisation of the service will be considered when the estimates for next year are being prepared. This course is open to the serious objection that the alterations which may be adopted will not be known till close upon the period when the next competitive examination will be held. In the meantime the young medical men who think of entering the public service will have made up their minds in favour of those two branches of which the conditions of service are known, and the Navy will be again unable to obtain the number requisite to fill up vacancies. It is quite clear that something must be done, and it is very difficult to understand the policy of postponing the consideration of so unavoidable a subject to a time when the office-work is increased by the additional labour involved in the preparation of the general estimates. Lord NORTH-BROOK is, we believe, fully alive to the necessity of obtaining medical officers for the Navy, and he may be well assured that he will never get anything like an adequate number until the conditions of service are greatly ameliorated. Among those which most urgently require attention are the rates of pay and half-pay, which

must be brought more into accord with those of the army medical officers; the system of compulsory half-pay must be modified, or some compensation granted for the loss of time it causes, and which seriously affects the rate of retirement; steps must be taken to assure to medical officers the choice of cabins in accordance with the regulations, and to prevent them being deprived of their right in this respect at the caprice of the captains; the rule requiring five years' service as Deputy Inspector-General before the officer becomes eligible for the higher grade, must be abolished; it would also be advisable to introduce a grade corresponding to that of Brigade Surgeon in the army, and to modify the rule respecting the age at which compulsory retirement is enforced, with a view to improve, to some extent, the prospects of promotion for the juniors. We sincerely trust that Lord NORTHBROOK will without delay direct his attention to this very important subject, as we feel assured the more he looks into it the more will he see the need for prompt action, and the sooner he puts the service on a proper footing, the more likely will he be to obtain an adequate supply of well-qualified candidates.

DR. GROSS of Philadelphia, in his work on Tumours of the Breast, has given statistics, partly original, partly obtained from other published sources, to show the natural duration of life in cancerous disease of the breast, and the influence upon it that partial or more complete operations have. It must be understood that Dr. GROSS's statistics refer only to malignant tumours of special histological characters—true carcinomata, and do not include all malignant growths met with in the female mamma. In 67 cases allowed to run their natural course the average duration of life was twenty-seven months, while in 224 cases, in which death occurred after operation, and with recurrence of the disease, the average duration of life was thirty-nine months; so that in these, the less successful cases, active surgical interference was enabled to add, on an average, a year of life in addition to the physical and mental comfort following the removal of a cancerous mass. But there is a better aspect of the question than this. Out of 519 cases in which an operation had been performed, as many as 47 were known to be free from any recurrence of the disease for periods varying from three to nearly sixteen years; 4 only of these 47 were dead, so that it is impossible to say how long the freedom from cancer will continue. The average time since the operation in the whole 47 was five years and nine months, and the disease had existed before operation on an average for eighteen months, so that the average duration of life in these cases, the majority of which were still alive, is seven years and a quarter. Dr. GROSS maintains that as death from metastases occurs at thirty-one months, and the average date of death of those who succumb with or without operation is thirty-three months, any patient who is alive and well, without any evidence of local or distal recurrence, three years after the removal of a cancerous tumour of the breast, may be considered to be cured. In the language of averages this assertion is no doubt sufficiently accurate, but there are so many cases on record where recurrence has been noticed at longer intervals, that, small though the percentage of such cases in the grand total is, it is obviously unsafe to

apply the average rule to individual cases, and speak with too much assurance of complete permanent recovery.

Valuable lessons are to be learnt from a study of the cases in which surgery fails to obtain results so good as these. One is the great frequency of local recurrence within three months from operation—more than 60 per cent.—with a steady and rapid diminution after that time. Another fact which comes out is that the axilla is far more often the seat of recurrence when the mamma only is excised than when the axillary glands also are removed. Each of these deductions points to the urgent necessity for complete, thorough operations, for cases in which the tumour reappears within a few weeks from its removal must be regarded as continuous growths rather than as true recurrences. Surgeons have naturally avoided opening up the axilla and interfering with the lymphatic glands unless they were evidently affected, and then oftentimes the prospect of doing good has been held to be too slight to warrant the operation. Where, however, the disease to be attacked is so deadly, bold measures are justifiable, and the only ones to be relied on. The direction in which all our recent experience points is that an operation for cancer should be not only early but very far-reaching, involving the removal of the neighbouring glands even when not palpably affected, and that in this way we may attain success far better than by less bold procedures.

In Dr. GROSS's statistics about one in six of the patients died of the operation itself, but this surely is a higher rate of mortality than is at all usual. Some years ago, before the application of strict asepticism to surgery, Sir JAMES PAGET spoke of 5 per cent. as the mortality which would probably always be met with. He was no doubt referring to the removal of the mamma alone, and the excision of the axillary glands increases the danger to some degree. But as by slow careful dissection injury to the bloodvessels can be obviated, and by well applied dressings and drainage, especially Listerian, the danger of retention and putrefaction of inflammatory exudation leading to blood-poisoning may be prevented, the additional risk is out of proportion to the subsequent advantage that accrues from this procedure. Such clinical experience as we have quoted above has an obvious bearing upon the obscure pathological question of the origin of cancer, and lends great support to those who regard it as in the first instance a local disease.

Annotations.

"No quid nimis."

M. PASTEUR'S INOCULATIONS.

OUR Paris correspondent enabled us to give, last week, a full account of M. Pasteur's remarkable communication to the Académie de Médecine, on his method of inoculation for the prevention of the "cholera of fowls." The facts are of great interest in their immediate application, and of still higher importance in the wider inferences which they suggest. M. Pasteur had previously ascertained that the disease is due solely to a microscopic organism which may be cultivated artificially, and, even after many successive cultivations, will still infallibly produce the disease. Of still greater importance, however, in connexion with human pathology, is the demonstration which his experiments supply, that a disease due to an organised contagium affords some protection

against its recurrence. A second attack is inversely proportional in severity to the first, and if the first attack was a severe one subsequent inoculation with the most virulent virus will produce no effect. The mere fact that the same organism, under different conditions of its own energy—differences which are expressed by no apparent morphological variation—produces the disease in different intensity, is one of great significance. Another important fact is that a very chronic form of the disease sometimes results from inoculation with a virulent virus, and that this appears to be due to the organisms becoming localised in certain organs, and remaining and developing there for months, and then suddenly passing into the blood, with the result of causing the bird's speedy death. The organism then contained in the blood is of considerable virulence, killing almost invariably. Its virulence is preserved by successive inoculations, if the interval between these inoculations is short, but is lessened if these intervals are long. Nevertheless, this virus, thus attenuated, will still produce an attack of the disease which protects against subsequent attacks. If the series of cultivations at prolonged intervals is extensive, the virus may ultimately lose all its virulence, apparently by its death. M. Pasteur attributes the attenuation to the influence of atmospheric oxygen, for he finds that if the organism is cultivated in hermetically sealed tubes, containing but little oxygen, the virulence remains unlesened, even after many successive growths at long intervals.

We have drawn attention to the chief feature of M. Pasteur's communication, not only on account of its interest and importance, but also to point out that its most important fact has been already anticipated by one of our own investigators in the same field. The fact is that successive cultivations may attenuate a virus, which, thus weakened, still confers protection against the inoculation of the virus in its most virulent form. The anticipation to which we refer is by Dr. Greenfield, and is of interest not only as a discovery of a general principle, but as showing that the observations of Pasteur have, indeed, the application to other diseases which this distinguished author suggests. We quote the anticipation in Dr. Greenfield's own words (THE LANCET, June 5th, p. 866):—"Further experiments have led me to the conclusion that the poison [of anthrax] becomes progressively less virulent in successive generations of artificial cultivation. I have thus been able to obtain a modified virus, which, when inoculated, produces much less severe symptoms, and appears to be partially protective against future more severe attacks."

CORK FEVER HOSPITAL.

A GENERAL meeting of the committee and subscribers of this institution was held on the 4th inst., to consider certain changes in the rules of the hospital as recently recommended by the Managing Committee, and to elect a resident medical officer and apothecary in the room of Dr. Adderley, resigned. A report was read from the medical officers, who entered a protest against the recommendations of the committee for the internal management of the hospital, and drew attention to Rule 4, which laid down the condition that the assistance of the physicians should be obtained before new rules were framed, a provision which was not acted upon. Further, they submitted that the physician in charge of a case was the only judge of the necessity of holding a consultation, but they had no objection to meet in formal consultation in any case involving special difficulty in its management, and suggested as a substitute for the rule of the committee, that the physicians when they thought it necessary in any exceptional case where there was a difficulty or doubt should hold formal consultations. As regarded the rule prohibiting the physicians prescribing any medicine not belonging to the Pharmacopœia and sanctioned by the committee, the medical

officers stated that they could not consent to be bound by any Pharmacopœia or by any other collection of formulæ, as such restriction would be detrimental to the interests of their patients, and would greatly hamper the staff in the discharge of their duty; while in reference to the latter part of the proposed rule, they reminded the committee that urgent cases might occur which, demanding immediate treatment, would compel the medical officers to wait for a meeting of the committee. At the same time the physicians did not object to consult as to the propriety of using an extraordinary remedy when the occurrence of an exceptional case might require to be given, when ordinary remedies had failed. After some discussion the further consideration of the matter was adjourned to that day fortnight, in order to give the subscribers an opportunity of considering it more fully. Mr. Atkins was unanimously elected resident apothecary.

NEW THEORY AS TO THE PATHOLOGICAL CHANGES IN THE BLOOD IN ACUTE RHEUMATISM.

AT the last meeting of the Cambridge Medical Society, held on Friday, Nov. 5th, Professor Paget, President, in the chair, Professor Latham advanced a new theory as to the pathology of acute rheumatism. He maintained that the first step was a lowering of the action of the "inhibitory chemical centre," or nervous centre, which controls oxidation in the muscular tissue. Following upon this, the oxygen from the oxyhæmoglobin, instead of entering the muscular tissue to be exhaled therefrom in the form of carbonic acid gas, had its sojourn in the tissue shortened, and passed into the blood in the form of lactic acid (a substance which appears in muscle almost instantaneously with its death); that the oxygen acted also more energetically on the muscular tissue, and the resulting lactic acid being oxidised rapidly in the blood, instead of in the muscular tissue, an abnormal amount of heat or pyrexia was developed.

He then argued that quina lowered temperature by simply impeding the carrying of ozone from the lungs to the tissues by the red blood-corpuscles, as in Binz's experiments with ozonised turpentine and guaiacum; and so the remedy might act beneficially in rheumatism, but would have no effect on the *materies morbi*. Salicylic acid, on the other hand, lowered the temperature and cured the disease by chemically combining with the substances from which the lactic acid is derived, and producing less heat than would result from the oxidation of that substance. He showed how the theory advanced explained the relapses which so often recur after apparent cure with salicylic acid, the necessity for large doses of the remedy, and the reason why it should be less curative in other pyrexial disorders, such as pneumonia, typhoid fever, &c. Referring to locomotor ataxy as an example, he suggested that possibly the local symptoms might be the result of the lactic acid acting upon the posterior columns of the spinal cord, producing functional change; and, in reply to a question in the discussion afterwards as to the connexion between rheumatism and chorea, considered that this disorder was the result of the lactic acid inducing functional change in the nervous centre which co-ordinates muscular movement, that centre being weak, and therefore a point of minimum energy, and this condition being hereditary or acquired. He also applied his theory to explain why the same cause (cold), which in one person appears to produce acute rheumatism, in others produces pneumonia, tonsillitis, &c.

Since the meeting Dr. Latham has extended his theory to diabetes. If it be true, it ought, he says, to explain the phenomena of that disease with a normal or subnormal temperature, and he maintains that the lowered nerve action is sufficient to do this. Salicylic acid may then (whilst the patient perhaps is taking ordinary diet) cause the sugar to disappear

from the urine and lessen the amount of that secretion without even altering the condition of the nervous system upon which the symptoms depend.

PREVENTABLE DISEASE AND SANITARY WORK IN INDIA.

THE Indian Famine Commission does not appear to have been very highly impressed with the progress of sanitary work and its influence on the prevention of disease in India. In the second part of their report they give an appalling picture of the loss of life by preventable diseases among the native population, and they say with reference to sanitary progress that "there is no room to doubt that the work hitherto achieved by district officers or the Sanitary Department falls very far short indeed of what is necessary to secure satisfactory improvement, or what the administration could effect if the matter were taken up seriously and funds were available." It seems to us that the apathy or indifference implied here is inconsistent with the concluding words of the sentence, to say nothing of the extreme difficulties which beset sanitary progress in India, arising from the habits of the natives and their prejudices, and which the Commission refer to. The observations of the Commission on the chronic character of the agencies which contribute to so formidable a proportion of fatal preventable disease, particularly in time of famine, the peculiar difficulties attending sanitary progress, and last, but not least, the limited funds available for securing this progress, prompt us to admire the advances which have already been made in the sanitary administration of India rather than to depreciate them and to impute indifference to the Government of India in the matter. We entirely agree with the Commission when they say that "every real step in advance made in this matter will have a most important effect on the health and the lives of millions and on their power of resistance in time of famine"; but we hesitate to accept their implied conclusion that the question of an "improved sanitation" (to use the marginal words of the report) had not been taken up seriously. It must not be overlooked, however, that, with one exception, the Commission was composed of Indian officials.

HYDROPHOBIA FIVE YEARS AFTER INOCULATION.

M. COLIN related to the Académie de Médecine, at its last meeting, a remarkable instance of prolonged incubation of hydrophobia. The case was that of a man who died a few minutes after being admitted (on August 31st) into the hospital, presenting maniacal excitation, exhortation, fear of drinking, and apprehensions, during more lucid moments, lest he should injure those about him. The autopsy showed no lesions, but some small cicatrices were noted on the left wrist and in the front of the thorax. Further inquiries showed that the man had been ill two days only. On the first he complained of a severe pain in the hepatic region and extreme thirst, although he could not drink; as soon as he raised a cup to his lips he was seized with shivering and spasm. The next day he complained of severe sense of constriction in the pharynx and a feeling of a wish to bite. The symptoms thus seemed clearly those of hydrophobia. No history could be ascertained of a bite from a dog during the previous five years. On Nov. 2nd, 1874, however, in Algeria, he had been bitten by a dog, which was attacking a comrade, to whose assistance he went, and who was also bitten. The latter had his wounds cauterised the next day, and died in eight days of hydrophobia. The patient of M. Colin was cauterised half an hour after the receipt of the bite. Some authorities, as Devergie, have maintained that the cases of prolonged incubation are really cases of "nervous hydrophobia," but the symptomatology of such a case as this seems too precise for the theory that an

attack so virulent could result from "nervousness." Hydrophobia is relatively common among the soldiers in Algeria, especially in the interior of the country, at the farms, where there are Arab dogs; and it is still more common among the civil population.

In regard to these prolonged periods of incubation in hydrophobia, of which this case presents an instance most remarkable, if not altogether beyond the reach of criticism, it is worth while to refer to one of the results obtained by M. Pasteur, of which we gave an account last week. It has long been a favourite explanation of these cases to suppose that the virus remained localised in the wound, developed there, and only caused the symptoms when, in consequence of some adventitious circumstance, it passed into the blood. M. Pasteur has shown that this explanation is, as regards some diseases, not a matter of theory but of fact. He has found that in the chronic cases of "cholera of fowls" the poison does develop in certain organs, and not, as in other cases, in the blood, and that when, after a variable period, the organised poison passes into the blood, severe symptoms come on rapidly, and the creature soon dies.

SUBJECTS FOR DISSECTIONS.

THE present supply of subjects is far from satisfactory. Notwithstanding that most of the London schools received some subjects during the summer months, a large number of students are still without parts. As a consequence of the inadequate supply applications have been made to some of the East-end Boards of Guardians, who have hitherto refused the privilege of allowing the schools to have the bodies of their unclaimed paupers for purposes of anatomical study. In most metropolitan unions this permission is readily given; and as by Act of Parliament only unclaimed bodies can be given up, it is difficult for us to appreciate the arguments which can have induced the visiting committee of the Shoreditch Workhouse to refuse their assent to the request. It is so obvious that, for obtaining any exact knowledge of the human body, a sufficient supply of subjects must be forthcoming, that we hope Boards of Guardians will not put forward any unnecessary difficulties, but will readily grant the authorities of the various medical schools every facility for carrying on such an all-important branch of medical education. The various safeguards laid down in the Anatomy Act are so stringent that the occurrence of any disrespect to the dead, or of outrage to the feelings of the relatives, is almost an impossibility; so that the lay authorities should carry out the spirit as well as the letter of a law which has been of so great service, not only to students of medical science, but to the community at large. We are glad to see that the Guardians of Bethnal-green have taken a fairer and more liberal view of this important question than their brethren at Shoreditch; and we hope that the other boards, to whom applications have been made, will follow their wise example.

REMOVAL OF FOREIGN BODIES FROM THE EAR.

M. ROUSTEN recently presented to the Société de Chirurgie of Paris a paper describing a means of removing foreign bodies from the ear by means of a cannula, and cited four illustrative cases in which it had been successfully employed. He urged the adoption of this plan in preference to the use of a syringe. A commission consisting of MM. Desprès, Delens, and Sée reported in reference to this suggestion that injections of water are nearly always successful, and are free from the risks attending the use of instruments of any kind, and that this opinion, in which all surgeons are agreed, cannot be upset by a record of four cases only. In the subsequent debate M. Gillette mentioned a case in which a pea was lodged in the external

auditory meatus for seven years notwithstanding many attempts to remove it. At the end of that time it germinated and swelled, and M. Gillette carefully syringed twice a day, with the result of removing it on the fourth day. We refer to this paper and discussion because the danger of using instruments for the removal of foreign bodies in the ear cannot be too much insisted on or too constantly borne in mind. It is so tempting to use some kind of forceps, or hook, or probe, or snare, but experience has abundantly proved the needless danger of all such procedures. In no case whatever should any instrument be employed until a thorough prolonged trial of well-directed syringing has been made and found to fail. And then, if further steps are necessary, anæsthesia should be considered a *sine quâ non* to any instrumentation, for a very slight movement of the head may easily suffice to destroy the membrana tympani and ossicles and set up mischief ending in deafness or even in death.

THE CASE OF DISTIN.

WE must disclaim any sympathy with the maudlin sentiment which makes some persons affect to find evidence of insanity in the case of every outrageous criminal. At the same time it is impossible not to feel that a grave public scandal will be created if Distin, the convict awaiting execution at Bristol, is hung without a medical inquiry. This man has, it seems, attempted suicide on no less than seven several occasions, once by taking vermin-powder, twice by trying to drown himself in the harbour, once by jumping over a bridge, once by jumping out of a window, once by hanging, and once by cutting his throat. Had he died on either of these occasions the verdict would doubtless have pointed to "temporary insanity" as the cause. Is there no ground for suspecting insanity now that he has, in a fit of jealousy, killed his paramour? There is also a history of injury to the head, and it seems his mental soundness has been actually suspected, as he was once submitted to medical examination by a surgeon now deceased. In the face of such a tale as this, we will not question the common sense and humanity of Sir William Harcourt by supposing that he will hesitate to interpose. Without waiting for any agitation or pressure, it is the plain duty of the Home Secretary to order a medical inquiry, whatever the result anticipated may be.

ON THE PART PLAYED BY THE STOMACH AND PANCREAS IN THE DIGESTION OF FAT.

A PAPER appears in the October number of the *Archiv für Anatomie und Physiologie* on the relative share taken by the stomach and the pancreas in the digestion of fatty substances, by Dr. Th. Cash. He begins by pointing out that Bernard long ago proved that the oleaginous constituents of the food must be emulsified before they undergo absorption through the agency of the intestinal, and especially of the pancreatic juices. His experiments were supported by those of Brücke, yet it has not been actually demonstrated that the breaking up of the fats into minute droplets and their investment with a soapy membrane, which is perfectly effected in the lacteals, is already accomplished in the intestine. Dr. Cash's experiments were undertaken under Ludwig's supervision, with this object in view. Dogs were kept fasting for eighteen hours or more. Food was now administered, and four hours subsequently the animal was killed with curare. The abdomen was at once opened and the intestine divided by ligatures into several portions of about a foot in length, so that each part retained the fluid it contained during life. The segments were opened, the contents tested with litmus-paper, and received in test-tubes. A quantity of water, equal to the fluid obtained, was added to each tube, warmed to 60° C., and filtered.

After the solid residue had been heated in this way several times with water, the cloudy fluid which had passed through the filter was placed in a cylindrical glass and subjected to centrifugal action for an hour or two. The oily portion of the fluid after this treatment swam upon the surface of the water. The contents of the small intestine were invariably found to leave an acid reaction, and on the surface of the fluid which had been subjected to centrifugal action, oil-drops accumulated of various sizes, which, however, never presented the slightest tendency to the proper colour of an emulsion, whilst the oil-drops could be easily made to coalesce, and could then be easily emulsified with a dilute solution of soda. It hence appears that fats are absorbed in the free state, and their conversion into an emulsion first takes place after absorption is effected.

THE KANDAHAR DESPATCHES.

THE *Gazette of India*, received by the last mail, publishes the despatches of General Primrose, of Aug. 30th, relative to the siege of the city after the Maiwand disaster. Par. 38, details the medical officers for the different gates and posts of the city in case of attack, with the following instructions, made by Deputy Surgeon-General O'Nial:—"Each medical officer will put permanently at his gate two dandies, or doolies. He will find some fixed place for them, in which they are always to remain, and he will take steps to insure that this place is known by the officer in command. On the assembly being sounded he will proceed at once with six additional dandies, or doolies, and the necessary surgical material, to his post, and will report himself to the officer commanding at the time. Medical officers will take care that their doolie-bearers are well acquainted with the route from their respective posts to the European and native Base Hospitals, and will take precautions against their crowding, or in any way obstructing the communications. Each medical officer will render assistance to all wounded or sick men, of whatever branch of the service, within his area. Surgical operations involving any delay are not to be performed at these posts. Assistance is to be limited to what is absolutely necessary to the men's transfer to the Base Hospital. The officers of the Base and Field Hospitals will have everything necessary for the treatment of the wounded always in immediate readiness." Par. 52, brings to the favourable notice of his Excellency the Commander-in-Chief the names of the following officers who, during the siege, rendered great assistance in the performance of their various duties:—Deputy Surgeon-General J. O'Nial, Surgeon-Major B. T. Giraud, Army Medical Department; and Surgeon-Major J. Arnott, Indian Medical Department.

MEDICAL MATTERS AT NEWCASTLE-ON-TYNE.

AS we anticipated, Mr. Page has been promoted from the position of Assistant-Surgeon to fill the office of Surgeon, rendered vacant by the resignation of Dr. Heath. The resignation of Dr. Heath is much felt by those interested in the work of the hospital and medical school. But it is gratifying to know that he retires in good health and with keen zest for the work of his profession. The elevation of Mr. Page creates a vacancy in the assistant-surgeonship, for which there will be a sharp contest. The candidates are: Mr. G. E. Williamson, F.R.C.S. Eng., Mr. J. D. Dixon, M.B., Mr. Hugh T. Bowman, M.S., M.B., and Mr. J. R. Baumgartner, M.R.C.S. It is probable that the contest will be principally between Mr. Williamson and Mr. Dixon, both of whom have strong claims on the governors. But it is no disparagement to Mr. Dixon to say that Mr. Williamson's claims are stronger than even his. He has distinguished himself as house-surgeon in the London Hospital, and succeeded in impressing nearly

all those who know him that he is fitted to take a high position in the practice of surgery. He is Mr. Dixon's senior; and not only has held the office of house-surgeon, but contracted typhoid in the discharge of his duties. He is, moreover, a Fellow of the College of Surgeons of England. There are over 100 students now in Newcastle, making it the largest provincial school, and larger than many of the London schools. Its pupils ought to do well. Not only is there a great field for medical and surgical teaching, but the Medical School is contiguous with the School of Physical Science, which is in a very thriving and effective state.

THE EDINBURGH GRADUATES' CLUB.

THE quarterly dinner of this club took place on Wednesday, the 10th inst., at St. James's Hall. The gathering of members was large. Prof. Lister occupied the chair. In proposing "Our Alma Mater," he discussed the reasons of the great success of the Scotch Universities, and attributed it largely to the fact that the teachers had time and inducement to stick to professorial duties, even after attaining eminence in practice. Dr. Matthews Duncan proposed the health of Professor Lister in terms of high appreciation. Amongst other things, he said that Professor Lister had been driven to the South of France to perform some of those experiments that had so much raised the character of surgery, a state of matters which, he thought, discreditable to our Government, which ought to further and reward such investigations. Amongst the visitors were Dr. John Williams, Dr. Stokes, &c. There has seldom been a more numerous or pleasant meeting of the club.

MEDICAL ATTENDANCE AND FRIENDLY SOCIETIES.

THE representatives of something like fifty Foresters' Courts have lately met in Plymouth, and discussed, among other things, the appointing a doctor for attendance on Friendly Societies and the families of members, the doctor to be confined to that work and prohibited from private practice. On being put to the vote, 28 were against and 25 supported the proposal. We agree with the majority in this division. To tie thousands of people to one doctor is to forget that the members of Friendly Societies, like other people, have their preferences, and if they have not, that at any rate their wives have. Moreover, the terms of remuneration offered for these appointments for doctoring wholesale are such as to attract only young men who want a start, and who then leave without any chance of establishing that permanent relation with a family which in a doctor is so valuable. "The family doctor" is not to be made in a year. He requires time and long experience. But he is as important to the working class as to the middle or upper class. These views are well indicated in a letter to the *Western Daily Mercury* by "Another Odd Fellow," and deserve great consideration.

TREATMENT OF FRACTURES AT THE ELBOW.

IN a recent paper Dr. Lewis S. Pilcher draws attention to the outward obliquity of the forearm, and records some measurements he has made with the purpose of testing its degree and constancy. He has measured the angle formed by the axes of the humerus and ulna, and found that not only does it vary considerably in different people, but even on the two sides of the same subject. The full, free, and proper use of the limb depends upon this angle, and it is necessary to attend to its maintenance when setting fractures near the elbow-joint; but as the sound limb is no certain guide for the injured one, it is difficult to determine upon the normal obliquity if it has been altered by the injury. Dr. Pilcher also urges the relaxation of all

muscles fixed to the fragments, and immobility of them until firm union has taken place; but we are unaware that these are other than the plainest and most universally held principles in surgery, although perhaps too often lost sight of in treating fractures near joints, from fear of ankylosis and the intervention of the bone-setting quack.

THE HOSPITAL SUNDAY FUND AND THE ALL SAINTS CONVALESCENT HOSPITAL.

THE papers announce the payment by the Lord Mayor of a cheque to the above hospital for £519 16s. 4d. The announcement is accompanied with the assurance that the Lord Mayor, before paying the money, had satisfied himself that a Committee of Management had been "duly elected." The Hospital Sunday Fund will stand still better in public estimation for thus vindicating its own Rule 4, requiring every participating charity to have a duly elected committee. We may fairly expect of the Distribution Committee that it will not again throw on the Council, or any member of it, the unpleasant duty of vindicating the most vital laws of the Fund. There is some reason to believe that the Eastbourne Hospital is not the only hospital that failed in the conditions of a grant.

"SUFFOCATING INFANTS."

ALLUSION having been obscurely made in the lay press to a suggestion of importance, for which the public are indebted to the late Mr. Wakley, we think it well to notice the matter specifically. In the course of his inquiries as coroner for Middlesex, Mr. Wakley discovered grounds for believing that a large proportion of the deaths by "overlying" were caused by the abuse of alcohol. These "accidents" occur chiefly on Saturday nights, following the weekly debauch of the poorer classes among whom they happen. The mischief works, as Mr. Wakley pointed out, in two ways: first, there is alcoholic poisoning through the milk, which tends to stupefy the infants, and predispose them to death; and, secondly, the semi-intoxication of the mothers throws them into a stupor, in which they lie upon and suffocate their children. It is as important as ever that these perils, incident to the practice of heavy drinking on Saturday nights, should be generally moderated.

PATHOLOGICAL SOCIETY OF LONDON.

WE remind our readers that the debate on Rickets will be opened on Tuesday next by Dr. C. Hilton Fagge. Drs. Barlow and Lees will also make a communication to the Society on the same subject, and Drs. Crisp and N. Moore are expected to take part in the debate, which will probably be adjourned to the next meeting of the Society. It is hoped that living and recent specimens will also be exhibited on the evenings specially devoted to the debate.

ROYAL COLLEGE OF PHYSICIANS.

THE Lumleian Lectures will be delivered this year by Dr. Reginald Southey—subject, "Bright's Disease"; the Croonian by Dr. Moxon, on the "Influence of the Circulation upon the Nervous System"; and the Gulstonian by Dr. Coupland, on "Anæmia." These lectures will be published in THE LANCET from the MSS. supplied to us by the several lecturers.

THE NEW JUDGE.

IT may interest our readers to be told that Mr. Watkin Williams, the newly-appointed judge, many years ago diligently studied medicine and completed his curriculum at University College; he acted as house-surgeon under Mr. Erichsen, the present distinguished president of the Royal College of Surgeons.

THORACENTESIS.

IN recent numbers of the *Gazette des Hôpitaux* is found a clinical lecture on Thoracentesis by M. Potain. He recommends the operation in all cases of empyema, and in all cases of serous pleurisy after fifteen to twenty days where purgatives and diuretics have failed to cause the absorption of the fluid. He urges that it should never be practised for hæmorrhax, on account of the difficulty of deciding when the source of the hæmorrhage is closed, and the impossibility of removing coagula; nor in pleurisy complicating phthisis with large cavities; but the early or middle stages of tubercle he regards as no bar to the operation.

THE Examinations at Oxford for the degree of Bachelor of Medicine will commence in the Medical Department of the Museum as follows:—The First (or Scientific) Examination, November 29th. The Second (or Final) Examination, December 6th. Candidates for either of these examinations and candidates for the certificate in subjects bearing on Preventive Medicine and Public Health should send in their names, on or before Nov. 15th, to the Regius Professor of Medicine, Medical Department, Museum.

AT the next quarterly meeting of the British Medical Temperance Association, to be held in the Medical Society's Rooms, Chandos-street, Cavendish-square, on Tuesday, Nov. 16th, 1880, at 4 P.M., the President, Dr. Richardson, will give an address on "Alcohol as an Antispasmodic—a Clinical Survey." "Exhibit: The Adulterants of Gin."

FROM recent advices it would appear that cholera is prevailing rather severely in Upper India; the Toondla Rest Camp is said to have been closed in consequence. Some anxiety is felt lest the disease should extend to the large camp to be formed at Lahore during the Durbar.

AMONG the new chairs to be established at Oxford, according to the "proposed statutes" drawn up by the University Commissioners, is a Waynfleet Professorship of Physiology, by Magdalen, when the revenues of the College will allow of it.

MR. EVAN ROWLAND, M.R.C.S. Eng., who served the office of Deputy Coroner to the late Mr. John Maurice Davies for twenty years, was on the 3rd inst. elected Coroner for the Aberystwith District.

LORD ROSEBERY was on the 6th inst. elected Lord Rector of Edinburgh University by a majority of 36 over Sir Robert Christison, Bart., the Conservative candidate, who polled 985 votes.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Wandsworth.—The reports of the medical officers of health (Mr. Kempster, Mr. Oakman, Dr. Nichols, Dr. Flowers Sutton, and Dr. Alexander Walker) for the several parishes in the Wandsworth district—namely, Battersea East, Battersea West, Clapham, Wandsworth, Streatham (including Balham and Tooting, and Putney and Roehampton), show, for the year 1879, an estimated population of 171,900, a birth-rate of 39·7 per 1000 inhabitants, and a death-rate of 20·5 per 1000, the death-rate for the whole of the metropolis being 23·3. The principal features in the returns of the causes of death during the year were the small mortality from small-pox, four deaths only having been recorded; the

"remarkable" decrease in the mortality from diarrhoea, attributed to the low temperature of the year; and the considerable fatality from diseases of the respiratory organs, constituting probably a third of the whole mortality of the district. "This heavy loss," say the reporters, "was no doubt due to the intense cold of the winter, both at the beginning and end of the year; and to the amount of rain which prevailed during the entire year." The following summary of the social position of the persons who died is of interest:—Nobility and gentry 3·3 per cent.; professional class 5·9 per cent.; middle-class 17·4 per cent.; industrial class 73·4 per cent.

The number of inquests held in the district during the year formed 3·7 per cent. of the total deaths, as compared with 4·2 and 5·0 per cent. in 1878 and 1877 respectively. On this it is observed: "We confess we do not find much satisfaction in this reduction of inquests, when we find that no less than eighty-nine persons died and were buried without attendance, certificate, or inquest. The number of deaths so summarily disposed of increases year by year, while the number of inquests steadily diminishes. No doubt a saving of time is effected to the coroner, and some expense avoided, by this economical arrangement; but is life rendered more secure, and crime made more difficult? The majority of those deaths are of children, and a large proportion of them are not even submitted to the coroner. Of these sixty-nine occurred in Battersea, nine in Clapham, six in Wandsworth, and five in Putney."

Wandsworth, it appears, suffers from an evil similar to that which so seriously affects Lewisham—namely, an inadequacy of the sewers to carry off storm and surface-water during rains such as were experienced in 1879. During the year regulations for the control of cow-houses were introduced, and are reported to have produced excellent effect. "The improvement in the dairies and cowsheds has been in some cases radical, necessitating rebuilding of the entire premises. We are certain," add the reporters, "that the regulations tend to improve the quality and purity of the milk by increasing the health of the animals, and to restore the confidence of the public in the use of one of the most valuable of our food supplies." Dr. Walker, the medical officer of health for Putney, observes on this subject: "The regulations admirably meet the wants of the milk trade, except in one particular—viz., the diseased condition of the cows. It is a fact of great importance that tubercular diseases are capable of being transmitted by cows' milk, and some sort of inspection of the condition of the animals should be instituted by qualified veterinary experts. Perhaps cows should be only allowed to be used until a certain age for dairy purposes, being then drafted to the slaughter-house." The Wandsworth district still suffers more or less from the piggery nuisance, but a number of piggeries were got rid of in the course of the year, and a hope is expressed that "the day is not far distant when the odour of a piggery will be unknown in the district." Hope also is expressed that the question of the water-supply of the district (as part of the greater question of the water-supply of the metropolis at large) has passed into a phase which will eventually lead to a supply from some other source than the Thames.

From the reports on the separate parishes of the district we gather that Mr. Kempster sees no evidence in his area of an injury to the health of young persons from the better education to which they are now subjected. Mr. Oakman attributes great success in the arrest of the progress of scarlet fever and measles to measures of disinfection, and he gives a noteworthy instance of the recklessness of builders in constructing new buildings. Investigating the conditions under which diphtheria prevailed in a family, it was found that the water-cistern had been placed immediately under the water-closet-pan, a layer of sawdust being spread over the cover of the cistern to soak up drippings from the closet, which was saturated. Dr. Walker comments upon the overflow of sewers, "the great fault of our modern sewage system," to which the parish under his charge is liable.

THE ARTISANS' DWELLINGS ACT.

A meeting of delegates from the Metropolitan Vestries and District Boards was held on the 5th inst. to consider a report respecting the Artisans' Dwellings Act, drawn up by a committee appointed on the 23rd January last, with a view to suggest for consideration such amendments in legislation on the subject as might seem desirable. The following were the conclusions of the report:—1. That no class of

citizens has a right to dwellings or sites for dwellings at the public cost; that only imperative considerations of public health can justify the outlay of the public money for such purposes as those of the Artisans' Dwellings Act; and if these considerations can be adequately provided for under Torrens' Act it is unjust to add to the heavy and constantly increasing weight of local taxation by enforcing the provisions of Mr. Cross's Act. 2. That owners of the class of property chiefly affected by these Acts should be placed under strong pecuniary inducements to keep it in proper and habitable condition; that if property has been kept in such a state as to be unfit for human habitation, or so as to become a nuisance, the penalty of such a course should fall upon the owners, and that the provisions of the Act should be vigorously applied whenever premises are in the condition contemplated by section 5, the Act of 1868, whether that condition has resulted from overcrowding, defective construction, the absence of sufficient area for light and air, or general dilapidation and uncleanliness. 3. That the working of the Artisans and Labourers' Dwellings Improvements Act, 1875, is impolitic and ruinously extravagant, and that in the interests of the ratepayers the provisions of the Acts known as Torrens' Act (1868-79) should be put in operation and fully exhausted by the local authorities throughout the metropolis before any further action is taken under Cross's Act. 4. That the cost of works under Torrens' Acts, whether executed by the owner or by the local authority, should be apportioned by the arbitrator between the parties holding the several freehold and leasehold interests, regard being had to their various responsibilities and the value of their interests. 5. That Torrens' Act, as amended, is capable of effecting most important results in improving and rendering healthy the habitations of the labouring classes in the metropolis, and that to this end it is desirable that each vestry and district board should adopt such measures by the appointment of standing committees, or otherwise, as may secure the prompt and effective working of the Act, and that if further powers be necessary in connexion with sanitary regulations, water-supply, or otherwise, it is desirable that such powers should be obtained without delay. 6. That the following amendments appear desirable in the Amendment Act. That section 5 be amended so as to limit the owner's power to require the local authority to purchase to cases in which the order of the local authority is to demolish the premises. That section 7 be amended by striking out the words "Local Government Board" in sub-section 1, and inserting in lieu thereof the words, "One of Her Majesty's principal Secretaries of State so far as relates to the metropolis." 7. That it will only be just and equitable that the compensation to be paid to the owners for acquiring lands should be a charge upon the whole of the metropolis, to be contributed by the Metropolitan Board of Works upon the application of the local authority. The other expenses to be paid by the local authority. 8. That it be recommended that all proceedings under the Artisans' Dwellings Acts 1875-9 be stayed until an opportunity has been afforded for a committee of the House of Commons to consider and report on the working of the Acts. 9. That it is desirable that a memorial to the Home Secretary should be prepared in accordance with the terms of this report, to be presented by a deputation at an early date, and that a copy of this report be forwarded to the Metropolitan Board of Works, with a suggestion that, if practicable, no fresh steps may be taken under Mr. Cross's Acts until such proposed inquiry has taken place.—A memorial prepared in conformity with these conclusions was read and adopted.

On the 8th inst. a meeting of the Council of the Charity Organisation Society was held to consider a report from a special committee appointed to examine the subject of artisans' dwellings in London. The committee reported to the effect that an amendment of the law was desirable, with a view of simplifying its operation; and recommended that a letter should be sent to the Home Secretary asking for the appointment of a departmental committee to make a searching and authoritative investigation into the causes of the delay, expense, and other evils that had attended the administration of the Artisans' Dwellings Act, and the sections of the Metropolitan Streets Improvement Acts (1872 and 1877) providing for the rehousing of persons displaced under these Acts.

THE BATH SMALL-POX SCANDAL.

A report of a committee of the Bath Board of Guardians on the late epidemic of small-pox in the city, adopted by the

Guardians at their meeting on the 20th ult., shows very clearly the neglect of the Urban Sanitary Authority of its duties during that outbreak. They appear to have shunted the duty of isolating cases upon the Board of Guardians, with the effect of causing part of the workhouse to be converted into a small-pox hospital, introducing the disease among the inmates, with the shocking result of infecting thirty-seven and killing five, and with the further not unimportant consequence of pauperising not a few patients. The actual number of patients admitted into the workhouse from without was not less than 140, and during the time these admissions were taking place the Urban Sanitary Authority—the Corporation of Bath—had an infectious-disease hospital of their own, situated not very distant from the workhouse, practically lying unused. The public are now asked to believe that the Corporation had "misconceived" their functions in respect to isolation! We have already had occasion to express our warm admiration of the way in which the Guardians came forward to make good the neglect of the Sanitary Authority, and we have avoided making any observations upon the manner in which their own special duties were performed under the circumstances, not wishing to appear to reflect upon a body of gentlemen who were placed under such unusual and difficult circumstances by the default of the Sanitary Authority. But the report now before us almost compels a reference to this particular subject. Isolation is but one cardinal element in dealing preventively with outbreaks of small-pox. Another cardinal element is the use of vaccination and revaccination in the infected localities. One of the most essential measures in steps taken for the purpose of arresting the spread of small-pox is the following up the cases as they occur by the vaccination and revaccination of the individuals residing in the same house with the patient or brought into contact with him, and this whether he be removed from the place and isolated in a hospital or not. Now the duty of securing this following up of the cases by vaccination rests with the Guardians, and the Local Government Board have issued very precise instructions as to the way it is to be performed. The reports we received at the time of the outbreak and immediately afterwards were remarkable for the absence of any reference to measures of this sort having been adopted in Bath; and the report now before us, although giving certain totals of vaccinations and revaccinations, makes no allusion to the execution of the measures advised to be carried out by Boards of Guardians under the circumstances of outbreaks of small-pox. The report, indeed, suggests that under the difficulties arising from the action of the Sanitary Authority with reference to the isolation of small-pox, and in their efforts to do the duties neglected by that authority, the Board of Guardians were compelled to deal imperfectly with their own special duties as to vaccination. We trust to learn that this was not the case.

It requires a robust faith in the principles of local administration not to have them seriously shaken as regards sanitary matters by this action of a local authority holding so high a position in the scale of municipal authorities as the Corporation of the ancient and wealthy city of Bath.

THE METROPOLITAN WATER-SUPPLY.

An adjourned meeting of representatives of the Vestries and District Boards of London was held in the Vestry Hall, St. Martin's-in-the-fields, on the 3rd inst., to consider their further proceedings in the matter of the water-supply of the metropolis. The resolution passed at the previous meeting (see THE LANCET, Oct. 30th) had been forwarded to the Home Secretary, but he had declined to state what intentions the Government had with reference to legislation on the metropolitan water-supply next session, expressing his willingness to receive any representations that the delegates might be desirous to make on the subject. Whereupon a resolution was passed to the effect "that the meeting having received the reply of the Home Secretary, the delegates should address themselves to the question of the proposed Water Trust; and that a sub-committee be appointed to prepare suggestions in reply to the Home Secretary's request, and to bring up a report for consideration." A committee of seven was appointed, and the meeting adjourned for a week—the intention being to offer these suggestions to the Government before the expiration of the time for Parliamentary notice.

THE RESTRAINT OF INFECTION.

At a recent meeting of the City Commissioners of Sewers, Dr. Sedgwick Saunders, the medical officer of health, asked their attention to the following anomaly in sanitary legislation. There were three persons lying ill with scarlet fever in a house in Mansell street, Aldgate. The father was a journeyman tailor working in his own room. On the outbreak of the fever he (Dr. Saunders) ordered that no more clothing should be brought into the house. The result was that the man's livelihood ceased, and he had an offer of breaking stones in the union or starving. With aid from the Mansion House poor box the man had been able to tide over the emergency. Dr. Saunders pointed out to the Commissioners the hardship occasioned to a poor man in requiring him to absent himself from his vocation in order to protect his neighbours from contagious disease. To such a man the law offered no compensation; and Dr. Saunders suggested that the sanitary authorities, whose funds were drawn from the public rates, ought to have power to apply their funds to the support of those people who were thus isolated from the practice of their vocation through considerations of public health.

PRIVATE MORTUARIES.

The Battersea Vestry has been instituting an inquiry into the private provision existing among undertakers in the parish for the custody of corpses previous to interment. Twenty-three undertakers' premises were inspected for the purpose of ascertaining the means they had at their disposal for the occasional care of corpses, and it appeared that three had private mortuaries, and nineteen take charge of corpses (if they receive them at all) in their shops, or in stables, or sheds. None of the undertakers knowingly take charge of the bodies of persons who have died of infectious disease. Mr. Whiteley, one of the members of the Vestry, on the report of the inquiry being presented, observed that he had twice attempted to obtain the sanction of the vestry for the erection of a public mortuary, and hoped shortly to have an opportunity of reopening the question. He thought it would be news to the Vestry as well as to the ratepayers at large that they already had twenty private mortuaries.

A protracted prevalence of scarlet fever in the village of Whittington was a subject of consideration by the Lichfield Board of Guardians, as Rural Sanitary Authority, at a recent meeting. The medical officer of health read a report on the subject, but after a desultory conversation it was allowed to drop, apparently on the ground that, as the persons attacked with the disease were only children, and that of the disease the weak alone died, energetic action on the part of the guardians was not called for. The chairman said that they were all greatly obliged to the medical officer of health (Dr. Monckton) for his report, but an appeal of that gentleman to the effect that if nothing was to be done with regard to Whittington the authority should turn their attention to Chase Town, where scarlet fever had broken out, appears to have been disregarded.

The Local Government Board has refused to constitute Bonchurch, in the Isle of Wight, an urban sanitary district, several of the inhabitants having recently memorialised the Board to this effect. It is understood that the Board is anxious to diminish rather than increase the number of sanitary authorities in the island, experience having shown that the inefficient sanitary administration of the island is largely dependent upon the too great number of its independent sanitary authorities. Dr. Ballard, of the Medical Department of the Board, has been recently engaged in an inquiry concerning the sanitary state and administration of the island.

A report has been presented to the Paddington Vestry by the medical officer of health on the alarming prevalence of scarlet fever and other fevers on the banks of the canal in the district, consequent, it is believed, on the foul condition of the water and the large accumulation of offensive mud in the channel. The vestry have instructed their solicitor to apply for an injunction to restrain the canal company from continuing the nuisance.

The Wandsworth District Board of Works have successfully prosecuted a builder for using mortar composed of mud and lime in the construction of certain houses. A fine of £3 was imposed, with £2 costs.

The Kingston Guardians have prosecuted an individual for neglecting to have his child taken to the public vaccinator for inspection on the eighth day after vaccination. The excuse made was that the child was indisposed at the time and unfit to be taken, but the magistrate refused to accept this explanation, and fined the defendant 15s. 6d., including costs.

The outbreak of scarlet fever at Chesham, to which we have referred more than once in our previous numbers, is we learn dying out, and the sanitary authority propose to expend £16,000 in sewerage the place. An application has been made to the Local Government Board for the loan of the money.

The new water-works at Doncaster, which have been completed at a cost of about £200,000, and have occupied six years in construction, were formally opened by the Mayor of the town a few days ago.

Dr. Ballard, of the Medical Department of the Local Government Board, has been engaged in investigating the outbreak of scarlet fever at Newlyn East.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality has been almost stationary during the past three weeks, but influenced by the unseasonably low temperature has exceeded the average for the time of year. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5442 births and 3258 deaths were registered last week. The births exceeded by 257, whereas the deaths were 17 below, the average weekly numbers during 1879. The deaths showed an increase of but 14 upon those returned in the previous week, and were equal to an annual rate of 22·7 per 1000, against 22·6 in each of the two preceding weeks. The lowest death-rates in the twenty towns last week were 15·6 in Portsmouth, 18·3 in Sheffield, 18·8 in Plymouth, and 20·5 in Birmingham. The rates in the other towns ranged upwards to 25·9 in Manchester, 26·1 in Leicester, 30·1 in Salford, and 30·3 in Liverpool. During the past five weeks of the current quarter the death-rate in these twenty towns averaged 22·2 per 1000, against 21·0 in the corresponding periods of the four years 1876-9.

The deaths referred to the seven principal zymotic diseases, which had declined from 1239 to 473 in the ten preceding weeks, further fell to 428 last week; of these, 150 resulted from scarlet fever, 78 from diarrhoea, 70 from fever (principally enteric), 50 from measles, 49 from whooping-cough, 24 from diphtheria, and 7 from small-pox. The annual death-rate from these seven diseases averaged 3·0 per 1000 in the twenty towns, and ranged from 0·7 and 1·9 in Plymouth and Sheffield, to 5·8 and 6·5 in Sunderland and Salford. The 150 deaths from scarlet fever showed a decline of 17 from the high numbers in the previous week, and the largest proportional fatality in Norwich, Sunderland, Oldham, and Manchester. Measles was most fatal in Salford, and whooping-cough in Portsmouth. The death-rates from enteric fever were proportionally excessive in Bradford, Leicester, and Portsmouth. The 24 deaths from diphtheria included 15 in London, 2 in Bristol, and 2 in Birmingham. All the 7 fatal cases of diphtheria were returned in London, where the prevalence of this disease again shows a tendency to increase. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 77 and 105 at the end of the two preceding weeks, further rose to 114 on Saturday last; the number of new cases of small-pox admitted to these hospitals during last week was 24, against 12 and 38 in the two previous weeks. The Highgate Small-pox Hospital contained 9 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 333 in the eight preceding weeks, further rose under the influence of the low temperature to 355, but showed no excess upon the corrected average number in the corresponding week of the last ten years; 220 resulted from bronchitis, and 92 from pneumonia. The annual death-rate from lung diseases was equal to 5·1 per 1000 in London, and to 8·3 in Liverpool.

Of the 3258 deaths in the twenty towns last week the

causes were duly certified by a registered medical practitioner or by a coroner in all but 75 cases, or 2·3 per cent. The proportion of uncertified causes of death did not exceed 1·3 per cent. in London, while it averaged 3·2 per cent. in the nineteen provincial towns, and was largest in Bradford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 24·2 per 1000, against 19·6 and 24·2 in the two preceding weeks, and exceeded the average rate in the twenty large English towns by 1·5 per 1000. The rates in the eight Scotch towns ranged last week from 17·5 and 20·6 in Perth and Aberdeen, to 25·5 and 28·4 in Paisley and Leith. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 107 and 149 in the two previous weeks, declined again to 115 last week; they included 54 from scarlet fever, 20 from fever, 15 from diphtheria, 15 from diarrhoea, 8 from whooping-cough, 3 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 4·6 per 1000 in the eight towns, and was 1·6 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the eight Scotch towns ranged from 0·7 and 2·0 in Greenock and Aberdeen, to 5·6 and 6·3 in Glasgow and Edinburgh; scarlet fever showed fatal prevalence in each of the two last-mentioned towns. The fatal cases of scarlet fever in the eight towns, which had been 47 and 51 in the two preceding weeks, further rose to 54 last week, and included 30 in Glasgow and 19 in Edinburgh. The 20 deaths referred to fever, principally enteric, showed an increase of seven upon the number in the previous week; 13 occurred in Glasgow, 3 in Edinburgh, and 2 both in Leith and Perth. The 15 deaths from diarrhoea showed a marked decline from the previous weekly number. Ten of the 15 deaths from diphtheria occurred in Glasgow, and 3 in Dundee; while 4 of the eight fatal cases of whooping-cough were returned in Dundee. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 120 and 121 in the three preceding weeks, further rose to 127 last week; the annual death-rate from these diseases last week was equal to 5·1 per 1000 in the eight Scotch towns, against 4·5 in London.

HEALTH OF DUBLIN.

The rate of mortality in Dublin again showed a marked excess last week. The annual rate of mortality in the city, which had been equal to 32·7 and 34·8 in the two preceding weeks, was 34·4 last week. During the past five weeks of the current quarter the death-rate in the city has averaged no less than 33·6 per 1000, against 21·0 in London, and 22·2 in Edinburgh. The 207 deaths in Dublin last week were within three of the number in the previous week, and included 36, or 17 per cent., which were referred to the seven principal zymotic diseases, corresponding with the number in each of the two preceding weeks; 13 resulted from scarlet fever, 9 from fever (principally typhus and enteric), 6 from diarrhoea, 6 from whooping-cough, one from measles, and one from diphtheria. No fatal case of small-pox has been recorded during the past fortnight. The annual death-rate from these zymotic diseases was equal to 6·0 per 1000 in Dublin last week, while it did not exceed 2·7 in London, and was 6·3 in Edinburgh. The fatal cases both of scarlet fever and whooping-cough corresponded with the number in the previous week, while those of diarrhoea showed a further decline. The deaths referred to fever (including typhus, typhoid, and simple), which had been 3 and 6 in the two preceding weeks, further rose to 9 last week; fever fatality in the city has been considerably higher during the past five weeks than it was during last quarter. The deaths of infants showed a further decline from recent weekly numbers, and the deaths of elderly persons were sixteen fewer than those in the previous week.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

TYPHOID FEVER IN QUEENSLAND.

An interesting report has been published by the Parliament of Queensland relative to the prevalence of typhoid fever at Toowoomba. It was held necessary to appoint a commission

of inquiry on the subject, which was formed of Mr. Wm. Henry Groom, M.L.A., Dr. John Thomson, and Mr. John Garget. The results of the inquiry show with what lamentable success the grossest sanitary evils attaching to old towns in England have been reproduced at the antipodes. Toowoomba is a municipality containing from 700 to 800 dwellings. The filth of these is deposited in about 500 cesspits, and the water-supply is derived from 300 wells. Both cesspits and wells are hollowed in a porous soil, the well being the deeper of the two, and as a rule twenty feet only intervenes between a cesspit and a well. That the liquid contents of the cesspits percolate into the wells there can be no doubt. Dr. Howlin gave evidence to the effect that "after a heavy rain the water had risen in the closet [cesspit] to within two or three feet of the seat, and after a week the whole would disappear; and he further noticed that a good drink of water from the well (the water-supply of the house), though not nauseous to the taste, would bring on a sharp outbreak of diarrhoea." The surface of the ground was not less filthy than the subsoil, and this neglect of cleanliness extended to banks and offices, and even Government properties. The *gaol*, indeed, appears to have been the only place kept in decent order. Under conditions of this sort it is not surprising to find that during a prolonged drought Toowoomba has suffered severely from typhoid fever. The Commission attribute the outbreak to the drought lessening the supply of water to the wells, and this becoming in consequence proportionally more impure; the "total neglect of ordinary cleanliness," and to ignorance. Toowoomba has, in fact, to begin at the beginning of decent requirements for health preservation, and the Commission recommend the "proclamation" of the district under the Health Act, 1872; the nomination of a medical gentleman either as a member or an officer of the Local Board of Health, and the appointment of a qualified inspector; the total abolition of all cesspits and the substitution of the dry-earth system; the proper disposal of slop-water; the stopping of the present well-water-supply, and the immediate use of reservoir water or rain-water; the supervision of Chinamen's gardens, the banishment of all pigs from within the municipality; the registration of disease; and the instruction of the young at school.

FEVER ON THE LOWER MISSISSIPPI.

A recent number of the United States National Board of Health Bulletin (vol. ii., No. 15) contains several interesting letters and reports on the subject of a prevalence of fever on the Lower Mississippi. The fever in question has given rise to wide differences of opinion as to its nature, and to a sort of disagreement between the State Board of Louisiana and the National Board. On the one hand, Dr. Steenberg and others representing the National Board, after personal investigation of the disease, have come to the conclusion that a mild form of yellow fever exists in addition to malarious fever connected with the rice-fields, and the National Board, guided by their judgment, have placed funds at the command of the State Board for use in instituting, as they think, necessary preventive measures against yellow fever. On the other hand, the medical advisers of the State Board, also after personal investigation, take a different view of the disease from the advisers of the National Board. They hold it to be solely a form of malarious, remittent fever, which is designated "rice-fever," and which has been increasing of late in prevalence on the Lower Mississippi contemporaneously with an increasing cultivation of rice in the lowlands. The State Board has accepted this conclusion, and declined the pecuniary assistance proffered by the National Board. The letters and papers deserve an attentive consideration.

YELLOW FEVER ON AN ENGLISH SHIP.

The *Liverpool Daily Post* reports that information has been received in Liverpool of a terrible outbreak of yellow fever on board the London ship *Jorawur*. The news comes from Roseau, Dominica, and is dated the 2nd ult. The *Jorawur*, a fine vessel of 1736 tons register, was formerly H.M.S. *Vulcan*, but was afterwards converted into a merchant vessel. It appears that on the 10th of September she put into St. Kitts for water and provisions, being then on a voyage from Guadaloupe to Trinidad. Shortly after leaving Guadaloupe yellow fever broke out, and twenty men, including the captain, were attacked, four of them dying. The *Jorawur* had been thirty-two days out from port when she put into St. Kitts, having met with strong

adverse currents. At St. Kitts she was put in strict quarantine, and afterwards supplied with provisions and water. It transpired that on the voyage of the vessel from Calcutta to Guadalupe there was serious mortality from yellow fever. She had on board 670 coolie emigrants, and twenty-seven of these died. The fever also attacked the crew, and eight men succumbed, making, with the four men who died on the passage from Guadalupe to St. Kitts, a total mortality of twelve men of the crew of the unfortunate vessel. The *Joravour* on leaving Calcutta had a crew of fifty hands, and when she reached St. Kitts they were reduced to thirty-eight.

The Bangor Town Commissioners, at a meeting held on the 1st inst., adopted a scheme to supply Bangor with water at an estimated cost of £7000. Dr. Cameron of Dublin made an analysis of the water from Conlig, where it is proposed to obtain the supply, and has stated that the water is a good one. A sum of £3000 will also be expended in the sewerage of the town.

ABSTRACTS OF THE

INTRODUCTORY ADDRESSES

*Delivered at the Dublin Hospitals and Medical Schools,
Session 1880-81.*

ROYAL COLLEGE OF SURGEONS' MEDICAL SCHOOL.

MR. SWANZY, speaking of ophthalmic surgery, said it was a branch of the medical profession which required special attention, as was evident from the census returns, which showed that one in every 852 of the population was blind. No branch of the profession possessed such means of exact methods of diagnosis and treatment—in fact, it was the nearest approach to an exact science which medicine or surgery possessed. Each step in the study of ophthalmic medicine and surgery showed how intimate in many instances was the connexion of diseases of the eye with general constitutional disturbance; for example, with Bright's disease of the kidney, diabetes, locomotor ataxy, &c. Like others, he recognised the fact that the student was over-lectured. Already the students had to bear their old burdens in the curriculum along with some of the new, but they might look to the professors for any assistance in their power in the removal of difficulties that beset their progress. They were all aware of the unsatisfactory condition of the army and navy medical services, and more especially of the Indian Medical Service. In the latter, more particularly since 1864, the officers had to endure insults, disappointments, and breaches of faith on the part of the Government which no doubt had influenced students in refraining from joining that service until they had received some guarantee that they would be treated as educated gentlemen who served a country. At present the College had under consideration a new scheme of medical education. The College was worthy of the esteem it had enjoyed, and of the love and pride of its licentiates, and it would be so to the end of time if preserved from the dire calamity of a conjoint scheme. Though that was not the place to discuss the question, yet he could not help saying that if a conjoint scheme were adopted the College would become a mere ornamental institution.

ST. VINCENT'S HOSPITAL.

DR. QUINLAN having alluded to the death of Mr. O'Leary, said that it was impossible to over-estimate the importance of clinical attendance in hospital, for without thoroughly studying disease at the bedside, they could never pursue their profession with safety to the public or satisfaction to their own conscience. No amount of reading or cramming could replace the careful personal observation in the wards, where, while so much appeals to the eye, the ear, and the other senses, still more is hidden from ordinary casual view, and is only to be appreciated by trained perception and patient inductive reasoning. The lecturer then referred to the ophthalmoscope, laryngoscope, spectrum analysis, microscope, &c., as aids to medical science; but while they carefully studied them, it would be a grievous error to rely

unduly upon them, and to neglect the careful painstaking clinical observation of disease. The physician who relied on the former and neglected the latter was like *Æsop's* astronomer who fell into the pit while he walked along, his eyes fixed upon the stars, but unobservant of the common objects in the path on which he walked. It was hardly necessary to allude there to the importance of medical chemistry, for physiology and pathology were year by year becoming applied branches of it, and pharmaceutical chemistry was annually adding to their armoury remedies of the most potent character. He could not refrain from expressing his wish that chemistry, botany, and physics could be learned and disposed of at the preliminary examination, before the student entered upon his four years' regular medical curriculum. There was too much forced into the present four years' curriculum; and while something was being constantly added on (as recently ophthalmology and vaccination) nothing had been taken off. The tension was becoming too great, and the obvious remedy was the diminution of the lectures to one course in each department, except anatomy and dissections, in which there ought to be two separate courses—a junior and a senior. The lectures should be changed from mere professional discourses to half of demonstration and a remainder of catechetical examination, and no student should get a certificate who had not attended a proper proportion of the lectures, and at each satisfied his teacher as to his knowledge of the previous one. He had tried this double system with success. In conclusion, he impressed upon them to devote themselves from the very beginning to their hospital and school studies, beginning now to take so keen and deep an interest in the furtherance of medical science and education, and by the fact that the profession was now, through its accredited representatives, always consulted on questions of medical reform by each successive Government.

MEATH HOSPITAL.

MR. HEPBURN having referred to the death of Deputy Surgeon-General Joshua Henry Porter, one of the brightest ornaments of the school of Irish surgery, next addressed his observations to those who had chosen medicine as their profession. Every facility would be afforded them to make the acquaintance of a practical knowledge of their profession easy to them. He often thought of those who then held the foremost rank in the hospital, and of whom, in the retrospect, we felt constrained to say, "There were giants in those days." But though their Graves, their Cramptons, their Stokes, their Porters, and other worthies had passed away—though those ancient great ones, who made so high a reputation for their hospital, were gathered to their fathers, the spirit which animated those great and good men, and which earned for them their high renown, has lived in their successors. If those mighty spirits of old could revisit the scenes of their former labours they would find an increasing body of intelligent, diligent, and high-toned medical students. In conclusion, students were not to suppose that idleness and dissipation were manly. There was no true manliness except in the honest performance of duty. What meant the monuments of Wellington, Nelson, and Gough, which adorned their city and park; had they been erected to do honour to individuals merely? No; but in order to keep alive in the hearts of each succeeding generation the virtues for which those heroes were distinguished. Duty, however, and the fear of God were the guiding principles of those great men, and they were influenced by those principles. If they, before whom life was just opening, were stimulated by the recollection of their noble deeds, he had no fear for their success in the profession they had chosen. He had not touched upon what might be called the burning questions of the day, which, in his opinion, were best reserved for occasions when discussion could be elicited; he had preferred rather to give them advice at the outset of their career as to how the golden opportunities presented to them in that hospital might be best utilised.

MATER MISERICORDIÆ HOSPITAL.

MR. MADDEN especially directed his observations to those young men who were about to join the ranks, on the nature of the profession they had chosen, and the method by which they might prepare themselves for its responsibilities. Unlike other professions, medicine was cosmopolitan, and,

whenever learned, might be practised in all countries and under all circumstances in which men are stricken by disease or accident and seek to escape from death. No portion of medical training could for a moment vie with engaging students in the hospital, to which all other branches of medical education should be made subservient. Pupilage did not end on emancipation from the terrors of examination. These but guard the portals of that wide domain of science which the longest life would not suffice them to explore thoroughly. In Dublin they had up to that time escaped any permanent settlement of those erratic medical hybrids—the lady doctors, despite the encouragement afforded them by the Irish College of Physicians in their hopeless contest against Nature's laws. There were some masculine women, just as there were some effeminate men. Neither were good types of their kind, and it needed no serious argument to prove the futility of any attempt founded on such exceptional cases on the part of either sex to fill the place and assume the functions of the other. He who would worthily fill the office of a true physician should possess a heart attuned to sympathy with suffering humanity, as well as a mind stored with the science which ministers to its relief. He recommended the cultivation of some taste for literary pursuits, and especially for the ancient literature of their profession. Those young men about to commence the study of medicine might be congratulated on the near prospect of having a feasible system of University education within their reach. In the new Royal University they might hope to find an institution in which every Irish medical student might seek, and if worthy might obtain, the great advantage of a university stamp on his medical qualification.

RICHMOND HOSPITAL.

MR. STOKES discussed some of the practical effects on medical and surgical science of the promulgation of the germ theory. A special interest attached itself now to this subject, as it had been the means of bringing about a revolution in surgical practice, which would be attended with as great, or even greater, benefits to humanity than even the discovery of Jenner. What it had done for surgery was already clear and defined, and he would be bold indeed who would fix the limits of what antiseptic surgery may yet do. In medical science the results were not yet perfectly tangible, but sufficiently so to prove that we are on the threshold of discovery of a therapeutic knowledge, to be made use of not merely for the cure, but also for the prevention of disease. The germ theory dealt simply with the competence of living organisms to produce the phenomena of disease, and did not necessarily take cognisance of the question whether or not organisms may originate *de novo*, and putrefaction had been proved beyond a doubt. The competence of germs to produce one kind of fermentation was admitted by all; but the competence of germs to produce the phenomena of disease was the special subject of discussion between the supporters and the opponents of the germ theory of disease. Referring to the loss they had sustained by the death of Sir Dominic Corrigan, the lecturer stated that even from his early boyhood Sir D. Corrigan was distinguished for zeal, earnestness, and assiduity, and his great success in after-life was mainly to be attributed to these qualities. Though not a voluminous writer, the contributions to medical literature of Sir D. Corrigan were, some of them, in truth, essentially classical. The outcome of close, diligent, and accurate observations, rendered fruitful by study, his contributions stood out in bold relief in the medical literature of this century as gems, the beauty and truthful lustre of which time could never tarnish. The present was a time in the history of the profession than which none was ever more important or critical. Never had public opinion been more or as much directed on it as at present, as evidenced by the deep interest now taken in all matters connected with sanitary science, in the efforts that have been made, and are being made, to reform professional examinations, in the fact of the universities.

LEDWICH SCHOOL OF MEDICINE.

MR. BENSON having alluded to the death of his predecessor, Dr. Rainsford, said that there was no profession possessed of such versatility, none in which so much liberty of thought and action was allowed, as in Medicine. Every

medical man worthy of his calling was an eclectic free to follow whatever line of action or investigation he might prefer, and bound only to succour the needy, to be present where there was disease or death. Were he to deal with the much-vexed question of medical education reform, he would have advocated a one-portal system for each of the three divisions of the kingdom, a minimum pass examination, held under Government, the passing of which was to be the *sine qua non* for registration, advising at the same time that the rights and privileges of the now existing schools, colleges, and examining bodies be so far unchanged that no student should be allowed to present himself for this examination until he had first obtained the double qualification from some of the recognised corporations—that, in fact, the student be allowed to study how he liked, and obtain his diplomas where he pleased, as at present, with this exception only, that it should not be possible for him to register until he had passed the Government, nor to present himself for this examination until he had obtained the double qualification. The tendency would then be to level up instead of down, and the only one to suffer would be the much-enduring student, who would have three instead of two examinations to pass; but the third being a repetition of the former would cause him little anxiety if he knew his work for the others. The lecturer concluded by referring to the use of the ophthalmoscope as an aid to medical diagnosis.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE inaugural address was delivered by Dr. John Malet Purser, King's Professor of Institutes of Medicine. Dr. Purser, in the course of his remarks, referred to the improvements in the new Physiological Laboratory, and impressed upon his hearers the great importance of a knowledge of physiology in medical education. He also drew attention to the amount of lectures required at the present time for medical students, declared it was overdone, and sympathised with those present at the large number of lectures at which attendance was required.

FILARIA DISEASE.

DR. PATRICK MANSON, of Amoy, in some "Additional Notes on *Filaria Sanguinis Hominis* and *Filaria Disease*," in the eighteenth issue of the valuable Chinese Medical Reports published by order of the Inspector-General of Customs at Shanghai, which has just reached us, continues the report of his extremely valuable and praiseworthy researches, and supplies additional evidence in support of the parasitic causation of Elephantiasis Arabum. Stimulated by the criticisms of the late Dr. Tilbury Fox, he specially set himself the task of gathering fresh proofs wherewith to meet the objections raised by that physician. It will be remembered that Dr. Fox argued that it was not proved that *E. Arabum* and lymph-scrotum are the same disease, but that the escape of *chyle* in the urine and into the scrotum probably marks quite a different condition of things from the ordinary effusion of *lymph* into the tissues. He said the chylous discharge might be due to filariæ or the adult nematoid, but its occurrence in the same subject with *E. Arabum* was merely a coincidence, just as chyluria and leprosy may coexist. To this Dr. Manson replies that it is at the outset a highly significant fact that the coincidence is not an infrequent but a common one, and he proceeds to add some very important new facts. From a consideration of six cases (met with in the course of nine months) of a "group of cases which belong strictly neither to pure elephantiasis nor to pure lymph-scrotum, but are either a combination of these diseases or the transitional stage of one passing into the other," he was struck by the fact that there was one feature common to all—viz., enlargement of the groin glands. On drawing off the lymph from these glands, he always found filariæ present, apparently old and moribund, though he could get none from the blood of the finger. But he also examined the lymph from the enlarged groin glands in a case of elephantiasis of the leg uncomplicated by any scrotal disease, and found filariæ both on the side affected and on the opposite side, though there were none in the blood. In

another highly interesting case of an "elephanto-œdematous" condition of the legs accompanied by transient fever, Dr. Manson discovered in an enlarged groin gland "one free filaria embryo and eleven ova," thus apparently establishing the fact that *Filaria Bancrofti* is oviparous.

Dr. Manson in former communications had remarked that the filaria embryos were often temporarily absent from the blood, and in the present paper he adds further important results. From a series of systematic examinations made every four hours, he found that "unless there is some disturbance, as fever, interfering with the regular physiological rhythm of the body, filaria embryos invariably begin to appear in the circulation at sunset; their numbers gradually increase till about midnight; during the early morning they become fewer by degrees, and by nine or ten o'clock in the forenoon it is a very rare thing to find one in the blood"; and he further made out that the same law holds good in the dog, though not to the same extent. In the light of his former discoveries, the adaptation of the nocturnal habits of the filaria to those of the mosquito is very suggestive.

The outcome of Dr. Manson's remarkable discoveries, made in a thoroughly scientific manner, with great persistence and expenditure of labour, and under many difficulties, in conjunction with those made by Lewis, Bancroft, and others, is summed up in the following conclusions, which we give in his own words:—

1. The parent filariæ live in the lymphatics; this is proved by their young and ova being found there, even when absent from the blood.
 2. They do not live in the glands, but in the lymphatic trunks on the distal side of the glands. Lewis and Bancroft found them in tissues some distance from any gland.
 3. They are oviparous.
 4. The eggs are carried by the lymph current to the glands, and being too large to pass ($\frac{1}{160}$ v. $\frac{1}{250}$ "), they are arrested there till hatched.
 5. After hatching, the free embryo passes along the lymph vessels, and enters the general circulation.
 6. Resting in some organ during the day, it circulates with the blood during the night;
 7. Whence the mosquito abstracts it, and acts as its intermediary host.
 8. In certain cases the ova, or embryos, produce obstruction of the lymph circulation through the glands, either directly by their size, or indirectly by causing inflammation.
 9. If the obstruction be partial, varicosity of glands and afferent lymphatics results, but by means of the anastomoses the lymph circulation is continued, carrying the embryos with it into the blood. Lymph-scrutum, or chyluria, or varicose groin glands, with hæmatozoa, are therefore the symptoms of partial obstruction of the lymphatics.
 10. If the obstruction be complete, one or other of two things happens: (a) The accumulating lymph so distends the vessels that they rupture, and a lymphorrhagia results, which is more or less permanent. In this case the lymph does not quite stagnate, but being able to circulate, though in a retrograde manner, it remains fluid. The symptoms of this form of obstruction are therefore lymphorrhagia from scrotum or leg, varicose glands, and filaria embryos in glands, and perhaps in discharged lymph, but none in the blood. (b) If the lymphatics fail to rupture, there is complete stasis of lymph, and excessive accumulation in the tissues on the distal side of the glands; solidification of the glands and tissues and elephantiasis results. No embryos are found in the blood, as none can pass the glands, and the parent worm or worms probably die choked, so to speak, by the stagnant and organising lymph and their own young. Consequently, in pure elephantiasis, as a rule, no embryos can possibly be found in the blood or gland lymph.
- Should these conclusions prove correct it is manifest that a remarkable discovery has been worked out; but still many facts press for solution, and of these some are as follow: Has the elephantiasis of Europe the same causation? As first steps in this problem, we know that filaria embryos have been discovered in the blood in England by Dr. Gabb, and we also know that dogs in France are largely the subjects of nematoid filariæ. Again, how is it that *E. Arabum* only occurs as a sporadic disease in Australia, where Dr. Bancroft discovered the parent filaria (probably introduced from Amoy by the Chinese)? And how is the curious inconstant co-existence of chyluria and *E. Arabum* in many countries explained, as, for example, the co-existence at Rio de Janeiro and not at Bahia, and the marked prevalence of lymph-scrutum in Lower Bengal?

THE SERVICES.

THE INDIAN MEDICAL SERVICE.

The Government of India have issued the following notification in the *Gazette*:—"With a view to afford medical officers of the Indian service employed on civil duties the opportunity of acquiring the latest experience of military medical administration before their nomination for promotion to the administrative grade, which nominations will be made at a date to meet as nearly as possible foreseen vacancies, the Governor-General in Council is pleased to notify that such officers, in the event of their not having performed military duty for six months within the three years immediately preceding the time of their probable promotion, shall, on nomination, be required to spend six months in medical charge of a native regiment at a station which is the head-quarters of a Deputy Surgeon-General, with whom they will be associated, in view to their acquiring a thorough acquaintance with the details of the office and the administrative system in force with British and native troops. An officer thus selected shall, when in charge of a native corps, relinquish the pay of his civil appointment, receiving in lieu that of an officer of his rank in medical charge of a regiment; but he will retain a lien on his civil appointment, to which he may, should he desire to do so, revert on the expiration of the six months, and await his turn for promotion. Officers, on proceeding to join regiments, and on reverting to civil duty, will be treated as officers on the military establishment, and travel under the warrants of their rank."

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Alfred Malpas Tippetts to be Brigade-Surgeon, vice J. C. H. Wright, M.D., granted retired pay; dated 25th August, 1880. Surgeons-Major Charles William Griffith, Hunter Alexander Colan, and Benjamin Hinde, M.D., are granted retired pay, with the honorary rank of Brigade-Surgeon; dated 10th November, 1880. Surgeon William Henry Garde to be Surgeon-Major; dated 14th October, 1880.

ADMIRALTY.—Surgeon William Tait, M.B., to the *Royal Adelaide*, additional, for temporary service at Plymouth Hospital.

Correspondence.

"Audi alteram partem."

THE INFECTION OF PHTHISIS.

To the Editor of THE LANCET.

SIR,—A very important fact is brought under consideration by the remarks and cases of Dr. Thompson, published in this week's *LANCET*—viz., that it is clearly possible for a healthy person to be infected by inhaling atmosphere rendered impure by the breath of a phthisical patient.

Another point of importance is, the pathological changes produced by this infective process, and the possibility of rapid recovery thus in contrast with the ordinary tubercular process. There appears to be some doubt respecting the question, whether the pathological changes in one case could be fairly called tubercular, though having many of the characters of that condition. It matters little, however, from a practical point of view, whether the inhaling of a tainted atmosphere produces tubercular or pyæmic conditions. It may be assumed that they are both of serious nature, and probably that the tubercular condition may co-exist with the pyæmic in certain cases.

The inquiry naturally occurs whether a large hospital for tubercular phthisis would be so beneficial as one where the atmospheric conditions of required purity could be more easily preserved. It also occurs to me to ask whether in the treatment of tubercular or any other form of pulmonary disease which renders the atmosphere dangerous for the patient and those around him there is any plan better than others for purifying the atmosphere. It was with this view that I sent a short paper to the meeting of the British Medical Association last August; and assuming the possibility of atmospheric disinfection for sanitary and other purposes, I have been waiting to see whether others have been directing attention

to this subject. There are, no doubt, many like myself, who have followed closely the progress of the germ theory, and have already applied the knowledge possessed on the subject to the treatment of pulmonary phthisis, &c. The question of atmospheric conditions evidently takes precedence of others when considering the subject of the treatment of phthisis pulmonalis.

I am, Sir, yours truly,

Savile-row, Nov. 9th, 1880.

ROBERT LEE.

MUSIC AS A THERAPEUTIC AGENT.

To the Editor of THE LANCET.

SIR, — The experiments which are related in THE LANCET of October 30th, on the physiological action of music, are interesting as affording a scientific explanation of a very familiar fact. That music quickens the breathing and makes the heart beat faster is well known, and it is not difficult to infer that this results from stimulation of the centres, regulating the cardiac and respiratory functions. It is instructive to learn that strychnia increases whilst bromide diminishes the effect thus produced on the circulation, but this is precisely what might have been anticipated *a priori* from our knowledge of the action of these drugs on the nervous centres. That idiosyncrasy is apparent in the effect produced is also, a matter of common observation. This is sometimes explainable, no doubt, by physiological peculiarities, as in the case of one of my relatives, who is, I believe, absolutely incapable of distinguishing any tune whatever. At other times the effect caused by musical sounds depends upon mental conditions, and is influenced by circumstances accompanying their production.

Whatever may be its mechanism, there is no doubt that music does exert a powerful physical action, and now that the fact is officially recognised by physiologists it may be well to call attention to the therapeutics of music, too much neglected, perhaps, at the present day. Pythagoras held that music might be made serviceable in the treatment of various diseases, and so have many generations of physicians down to our own time. "Music," says Esquirol, "acts upon the physique by determining nervous vibrations, by exciting the circulation. . . . It acts upon the morale by fixing the attention upon sweet impressions, and by calling up agreeable recollections." "In the treatment of mental disease," says the same author, "I have constantly used music. It calms and soothes the mind, although it does not cure; it is, however, a precious agent, and ought not to be neglected." Pinel, who was no mean authority, also gives ample proof of its value in his classical treatise upon mental alienation.

At the present day concerts are a standard element of treatment in many lunatic asylums, but as usually conducted they may be considered to form part of the general hygienic and moral treatment, and to differ entirely from the therapeutic selection of various kinds of melody, according to the particular condition of the patient.

The use of music as a remedy may be truly said to date from the very origin of medicine. In one of his odes Pindar relates that Æsculapius himself so treated some of his patients, and the god's conduct seems to have been followed by his mortal successors. "The confidence of the ancients in the therapeutic virtues of music," says Fournier-Pescay, "was carried to a great length, and our present knowledge does not allow us to believe with Homer, Plutarch, Theophrastus, and Galen, that it can cure the plague, rheumatism, or the bites of reptiles. One is also obliged to doubt the evidence of Diemerbroeck, Bonnetus, Baglivi, Kircher, Haffener, and Desault, concerning the cures which they attribute to music in cases of phthisis, gout, plague, hydrophobia, and bites of reptiles." If the word "reptiles" refers to the "tarantula," there is also high authority in favour of the opposite opinion. Speaking of the different means used to relieve the "tarantati," Hecker says that they were as nothing in comparison with the irresistible charms of musical sound. It was customary at the beginning of the seventeenth century for whole bands of musicians to traverse Italy during the summer months, and the cure of the "tarantati" in the different towns and villages was undertaken on a grand scale. The different kinds of "tarentella" were distinguished by different names, which had reference to the moods observed in the patients. "There was one kind of 'tarentella' which was called 'panno rosso'—a very

lively impassioned style of music, to which wild dithyrambic songs were adopted; another called 'panno verde,' which was suited to the milder excitement of the senses caused by green colours, and set to Idyllian songs of verdant fields and shady groves; a third was named 'cinque tempi'; a fourth 'moresca,' which was played to a Moorish dance; a fifth 'catena.'" The score of one of these dances, from Athanasius Kircher's "De Arte Magica," will be found in the Sydenham Society's translation of Hecker's very interesting volume.

Burton, in his "Anatomy of Melancholy," has a chapter entitled "Music, a Remedy," which contains a sufficient number of quotations to serve for a treatise upon the subject. Burton's opinion was most emphatic. "Besides that excellent power it hath to expel many other diseases, it is a sovereign remedy against despair and melancholy, and will drive away the devil himself." Amongst the curiosities of past medicine may be ranked Porta's theory of the specific property of sounds emitted through different kinds of wood. He believed that instruments made with the woods of medicinal plants produced different kinds of music, endowed with therapeutic virtues in the same diseases as those for which the woods themselves might be used. In the early days of electricity a similar idea was embodied in the Italian method of "intonnacature," which consisted of the application of sparks to the body through a tube containing any medicinal agent which might be indicated, and which was supposed to "dynamise" the spark with its special force. Quite recently the properties of different kinds of woods have been again discovered by a Paris physician, who has enriched science with xylotherapy, and there is good reason to believe that the same enlightened capital will soon give the world a new electrical method which will be uncommonly like its Italian predecessor. Fournier-Pescay, who contributed the article "Musique" to the "Dictionnaire des Sciences Médicales," relates a number of cases benefited by the use of this agent, which cannot possibly be controverted. Amongst these are several which are worthy of mention. His own child was relieved of "constant pain" and insomnia by the sound of the flute, which was recommended, by the way, by Pliny for the cure of sciatica. Vocalisation in a minor key was afterwards substituted with good effect. Dodart (says the author) relates the case of a musician who was cured of a violent fever by the pleasure he experienced at hearing a concert in his room. Bourdois de la Mothe prescribed music as a last resource under the following circumstances:—A young lady was dying on the eighteenth day of a severe fever. The pulse was vermicular, the *facies* Hippocratic, and the extremities icy cold. Upon leaving the room, Bourdois caught sight of a harp, and it occurred to him to make the experiment. The husband's scruples gave way to the hope of saving his wife, and an excellent harpist was fortunately at hand. For thirty long minutes no change was observed, but ten minutes later the breathing improved, becoming deeper and quicker. The musician redoubled her efforts. A warm glow was diffused through the cold limbs, the pulse became more full and regular, and an epistaxis to the amount of eight ounces occurred, after which the patient recovered her speech. A few days later she was convalescent.

Desessarts, in a work published in 1811, relates similar cases, though of lesser gravity. It would be easy to fill pages with anecdotes of the effects produced upon individuals by the sound of music. Boyle speaks of a Gascon knight who was unable to hold his water when a certain instrument was played; and the same thing has been recorded of others. But the most remarkable observation, from a medical point of view, is related by Hallé, and quoted by Fournier-Pescay in the article already mentioned. A very sensible woman, and an excellent musician, could never hear her pupils play a certain piece, arranged for the piano and several harps, "without experiencing a uterine evacuation resembling the menstrual discharge."

Those who may wish to pursue the subject further will find plenty of information in the authors whom I have quoted, and particularly in Fournier-Pescay. There is an interesting account of the emotional effects produced in two elephants by different kinds of music, played as an experiment in their hearing, before a number of scientific men, at the Paris Jardin des Plantes; and, besides a mass of erudition and anecdote, there are also a number of clear directions as to the choice of suitable melodies for particular cases.

I am, Sir, yours faithfully,

Paris, Nov., 1880.

OSCAR JENNINGS.

"DENTAL SURGEONS," "SURGEON-DENTISTS."

To the Editor of THE LANCET.

SIR,—I trust that in fairness to the dental profession you will allow me to make some remarks upon Mr. Napier's letter in THE LANCET of to-day. Mr. Napier writes as though the Dental Act had for the first time conferred upon unqualified dentists the right to adopt the title Surgeon Dentist or Dental Surgeon, the truth being that they possessed this right, virtually undisputed, before the recent legislation. Attempts had been made some years previously to prevent them so styling themselves, but it was ruled by the higher courts of law that unqualified persons *bond fide* in practice as dentists might use these designations as they had used them unchallenged for generations; and an appeal to confirm a conviction in a test case—a very flagrant case—was literally "pooh-poohed" by the Lord Chief Justice. Further, it was found that there was the utmost unwillingness on the part of the Legislature to interfere with these "vested interests." It, therefore, became a question either of allowing in future an indefinite number of uneducated men to commence practice as dentists, or of permitting those already in practice to continue, and preventing the abuses for ever after. This latter the Dentists Act has done. It is still possible for the Legislature, in amending the faulty Medical Act of 1858, to introduce a clause forbidding under any circumstances the misuse of the prefix "surgeon;" and, I may be allowed to remind you, dentists are not the only offenders in this matter, for a quack styling himself surgeon-chiropodist or using a similar deceiving title cannot, in the present state of the law, be interfered with.

In conclusion, I must beg to state once more, in order to correct an important misapprehension, that the Association of Surgeons Practising Dental Surgery has no valid title to speak in the name of those it professes to represent. The majority of dental surgeons are not members of it; and at the time it was started its foundation was protested against in your columns by a large number of dental surgeons, comprising those whose scientific and other work has been mainly instrumental in placing dentistry in its present improved position.

I remain, Sir, your obedient servant,

Wimpole-street, Nov. 6th, 1880.

HENRY SEWILL.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—I cannot hope to stem the torrent of obloquy directed by your articles against the staff of Guy's until I show that it is undeserved; but I think it would have been more generous to have written in our aid than for our discomfiture. The withdrawal of an injudicious letter, however humiliating, may yet be wise, when it saves from dismissal two of our seniors. The withdrawal may be regarded as a defeat, but it is by no means an "unconditional surrender." There is, indeed, much yet to be done. I have shown elsewhere how strangely altered the governing body has become, under the process of self-election, from that which Thomas Guy appointed. It is now *vis consili experts*. To obtain some alteration in the constitution of this body so as to prevent recurrent disaster, and to secure a fair representation of the profession in council, ought to be the endeavour of every one interested in hospital management. We are told that we represent the profession, and that it is humiliated. If so, whence should have come our support? Of the dozen medical schools in London which has moved to our assistance? Of the hundreds of teachers two only have taken up our cause.¹ The profession has looked on amused but not self-interested. It would see the hospital dismantled, the junior staff ruined, and four hundred students scattered to the winds before it would move a finger in our support. And further, we are assured on every side that there are hungry malcontents but waiting for the fall of a great reputation to rush in and plunder among the ruins.

I am, Sir, your obedient servant,

R. CLEMENT LUCAS, B.S.

¹ I refer to the generous letters of Mr. Brudenell Carter and Mr. T. Holmes.

CALF LYMPH.

To the Editor of THE LANCET.

SIR,—Having had several calves placed at my disposal for the purpose of vaccination by a farmer friend, I have for the past three weeks been operating upon them and from them. I have most successfully vaccinated several children. The subject of animal vaccine being now to some extent before the profession of this country, I am desirous of using my present stock of calf lymph for the benefit of my brother practitioners; and it occurred to me that the best medium of effecting such a distribution would be through THE LANCET, as more medical men would get the opportunity of testing for themselves the effects of pure animal vaccine than if I gave my stock away amongst my private friends. I may state that I vaccinated my first calf from lymph procured from the animal vaccine establishment at Utrecht; and that all the steps of my progress are known to Dr. Buchanan, of the Local Government Board, and to Dr. Robert Cory, of St. Thomas's Hospital, the latter gentleman having kindly come down here and assisted me at the vaccination of two calves. I will be happy to send two tubes of lymph to any medical man desirous of using it, on his sending me a case to convey the tubes in, and a stamped addressed envelope; and, in conclusion, I must ask for a report of the success, or not, of the lymph from every person obtaining a supply.

I am, yours faithfully,

Manningtree, Nov. 9th, 1880.

J. W. COOK, M.D.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a meeting of the Council, held on Thursday last, the minutes of the previous meeting were read and confirmed; Mr. Birkett was re-elected member of the Board of Examiners in Dental Surgery; and Sir James Paget's motion, to give up after September, 1881, the preliminary examination held by the College, was carried and referred to a committee to consider and report thereon. Mr. Holden's motion to discontinue the annual Report of the President on the affairs of the College was deferred.

Obituary.

DR. WILLIAM AITKEN,

DEPUTY SURGEON-GENERAL, MADRAS ARMY.

WE regret to announce the sudden death of Dr. William Aitken, at Douglas, Isle of Man, on Nov. 3rd, probably of heart disease, but more likely of apoplexy, as he had never complained of any cardiac symptoms, and was apparently in rude health up to the very moment of his death, which took place while he was sitting quietly reading a book in his chair about ten o'clock at night.

Dr. Aitken was born at Dunbar in 1819, and was therefore sixty-one years of age. He was a graduate of Edinburgh University, and for some time filled the chair of Midwifery in the Madras Medical College. He came of a family of doctors, for although his father was not one, three of his uncles were, and all of them were in the Public Services. Indeed, strange to say, the last of them died only, at the age of ninety-one, about ten days before him. That was James Aitken, of Talbot-square, who, after being fifteen years Master of the Mint at Madras, retired some fifty years ago, and was ever after a Government pensioner.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—In reference to a paragraph which appeared in our last issue, we are asked to state that two graduates of Christ Church, Oxford, were bracketed equal for the £125 scholarship—viz., Mr. George Gresswell and Mr. J. Holdsworth Fisher. Fourteen candidates presented themselves, of whom three were B.A. Oxford, three B.A. Cambridge, and six matriculated students of the University of London.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on Tuesday and Wednesday last:—

Edwin F. Hatton, Toronto, Canada; Owen H. Evans and John S. Collins, Dublin; Francis R. S. Corser and Manley M. Fitzpatrick, Edinburgh; Herbert Owen, Stephen T. Salter, and R. L. Knaggs, Cambridge; Henry Mason, Glasgow; Archibald Watson, Paris; John W. McVitie and Rowland Owen, Liverpool; Frank Harrison, Sheffield; Charles D. Nuttall, David N. Ruck, Charles B. Meller, John T. Tupholme, Henry W. Dodd, and C. Richmond Benson, St. Bartholomew's Hospital; Edwin W. Reilly, Calcutta and Edinburgh; William P. O'Connor, University College; Charles J. Power, Cambridge and St. Thomas's Hospital; George W. B. Slader, Alfred P. H. Griffiths, James A. Marsden, Henry C. E. Cooper, Ralph H. Browne, and William W. Floyer, Guy's Hospital; Edwin Creighton, St. Thomas's Hospital; Aubrey S. Findlay, Middlesex Hospital; John Maye, London Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 4th:—

Bird, Ashley, Clifton, Bristol.
Burton, Charles Fred., New John-street, Birmingham.
Clatworthy, Herbert, Chatham, Kent.
Jenkins, Thomas Griffith, Colomenely, Ruthin, N. Wales.
Trevor, Henry Octavius, Nether Stowey, Somerset.
Willie, John, Cloughton, Scarborough.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Edalji Dorabji Patel, Bombay; Charles Watts Whistler, St. Thomas's Hospital.

MR. OLIVER PEMBERTON, F.R.C.S., of Birmingham, has been placed on the Commission of the Peace for the county of Warwick.

MR. EDWARD BATES, late Medical Officer for the Bonvilstone District of the Cardiff Union, has received a superannuation allowance of £30 a year.

A LATE ATTENDANT on the insane at Northumberland House, Stoke Newington, was last week fined £15 at Bow-street Police Court for wilfully neglecting a patient who committed suicide.

MR. EDWARD RODGETT, of Darwen Bank, Preston, has given the sum of £4000 for the erection of a detached infirmary in connexion with the Royal Albert Asylum, Lancaster. The occurrence from time to time of cases of infectious disease amongst the inmates of the asylum has drawn attention to the need of such a provision as the generosity of Mr. Rodgett has now supplied.

SANITARY INSTITUTE OF GREAT BRITAIN.—At a recent examination held by the Institute, seven candidates were present, and certificates were awarded to H. P. Boulnois, M. Inst. C.E., W. K. Burton, A. Harland, and C. Innes, M. Inst. C.E., who passed the examination for Local Surveyors; and a second certificate was awarded to A. Harland, who also passed the examination for Inspectors of Nuisances.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.—The following officers have been appointed for the session 1880-81:—President: George Johnston. Vice-Presidents: John T. Banks, Walter G. Smith. Council: J. H. Benson, F. Churchill, J. M. Finny, T. Fitzpatrick, A. Foot, S. Gordon, T. W. Grimshaw, R. J. Harvey, Thomas Hayden, H. Kennedy, J. W. Moore, J. M. Purser. Honorary Secretary and Treasurer: Alex. Nixon Montgomery.

UNITED HOSPITALS RIFLE ASSOCIATION.—On Wednesday, the 3rd inst., the first meeting of this Association took place at Wormwood Scrubs. The Association was formed last July for the purpose of uniting all volunteers of whatever corps, at the different hospitals, and improving their shooting by offering a challenge cup to be competed for annually by hospital teams. Three hospitals, Guy's, King's, and St. Bartholomew's, have already joined, and the treasurer has a large sum in hand for the cup. It is hoped that by next year the Association may be in so flourishing a state as to warrant an application to the U. R. A. for leave for the competition to be held at Wimbledon. The meeting on Wednesday attracted a large number of men, who were divided into three classes, marksmen, drilled members and recruits, Queen's ranges.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. Dunstan Leech, late of Witley, bequeathed £100 to the Cottage Hospital, Witley, £200 to the Guildford County Hospital, and £200 to University College Hospital.

SURGICAL SOCIETY OF IRELAND.—The following are the office-bearers for the ensuing session:—President: Alfred H. M'Clintock. Vice-President: Samuel Chaplin. Council: Edward H. Bennett, Philip Bevan, William Colles, Anthony Corley, Henry G. Croly, Edward Hamilton, J. S. Hughes, Archibald Jacob, Rawdon Macnamara, Edward D. Mapother, Humphrey Minchin, E. Stamer O'Grady, George H. Porter, B. Wills Richardson, Wm. Roe, Philip C. Smyly, Wm. T. Stoker, William Stokes, Wm. Thomson, Jolliffe Tufnell, William Wheeler. Honorary Secretaries: Messrs. Richardson and Tufnell.

NATIONAL EYE AND EAR INFIRMARY, DUBLIN.—This institution will shortly be removed to Molesworth-street, where a suitable house has been obtained, which will give the necessary accommodation required when certain alterations and additions have been carried out. The new hospital will contain twenty-six beds, with separate day-rooms for men and women, operating-room, board-room, consulting-room, waiting-rooms, &c. The architect's plans have been approved of by the Managing Committee, but no works will be actually contracted for until the required money has been obtained, or a reasonable prospect of obtaining it exists. About £500 is still required.

THE ROYAL SOCIETY.—The following is the list of officers and council nominated for the year ensuing. The elections will take place, as usual, on St. Andrew's Day, November 30th:—President: William Spottiswoode, M.A., D.C.L., LL.D. Treasurer: John Evans, D.C.L., LL.D. Secretaries: Professor George Gabriel Stokes, M.A., D.C.L., LL.D.; Professor Thomas Henry Huxley, LL.D. Foreign secretary: Professor Alexander William Williamson, Ph.D. Other members of the council: William Henry Barlow, Pres. Inst. C.E.; Rev. Professor Thomas George Bonney, M.A.; George Busk, F.L.S.; Right Hon. Sir Richard Assheton Cross; Edwin Dunkin, V.P.R.A.S.; Alexander John Ellis, B.A.; Thomas Archer Hirst, Ph.D.; William Huggins, D.C.L., LL.D.; Professor John Marshall, F.R.C.S.; Professor Daniel Oliver, F.L.S.; Professor Alfred Newton, M.A., Pres. C.P.S.; Professor William Odling, M.B., V.P.C.S.; Henry Tibbatts Stainton, F.G.S.; Sir James Paget, D.C.L.; William Henry Perkin, Sec. C.S.; Lieutenant-General Richard Strachey, R.E., C.S.I.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

- BISS, C. T., M.B., M.R.C.P.L.,** has been appointed Assistant-Physician to the Middlesex Hospital.
- BOYD, R. J., L.R.C.P.Ed., L.R.C.S.Ed.,** has been appointed Assistant Medical Officer to the Cambridge, Isle of Ely, and Cambridge County Asylum.
- BRODIE, W. H., M.B., C.M.,** has been appointed House-Surgeon to the Northern Infirmary, Inverness.
- BURGESS, E. A., M.R.C.S.E., L.S.A.L.,** has been appointed Medical Officer to the Clun District of the Clun Union.
- CASE, P. W. P., M.B., C.M.,** has been appointed Assistant Medical Officer to the Infirmary of the Whitechapel Union, vice Gibson, resigned.
- CLARK, A., M.A., M.D., F.R.C.P.,** has been appointed Consulting Physician to the North-West London Hospital, Kentish-town-road.
- CUNNINGHAM, A., M.B., C.M.,** has been appointed Medical Officer to the Sydney District of the Chepstow Union, vice Tackwell, resigned.
- EDWARDS, J. P., L.F.P.S.G., L.S.A.L.,** has been appointed Medical Officer to the Workhouse of the Wolstanton and Burslem Union, vice Kendall, resigned.
- FITZMAURICE, U., L.K.Q.C.P.I., L.R.C.S.I.,** has been appointed Medical Officer to Listowel Workhouse.
- GIBSON, J. H., M.D., M.Ch.,** has been appointed Medical Officer to St. John's-wood District of the St. Marylebone Union, vice A. J. Bell, resigned.
- GILBERTSON, R., M.R.C.S.E., L.S.A.L.,** has been appointed Consulting Surgeon to the Cardiganshire Infirmary.
- GRACE, H., L.R.C.P.L., M.R.C.S.E.,** has been appointed Medical Officer of Health for the District of St. George, Gloucester, for one year.
- HADDOW, Mr. G.,** has been appointed Junior Clinical Assistant to the Glasgow Hospital and Dispensary for Diseases of the Ear, vice Mr. W. B. Violette, whose term of office has expired.

HARRIES, T. D., L.R.C.P.L., F.R.C.S.E., has been appointed Consulting Surgeon to the Cardiganshire Infirmary.

JONES, M., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Borough of Aberystwith, for one year. £50 per annum. Also Consulting Surgeon to the Cardiganshire Infirmary.

KEETLEY, C. B., F.R.C.S., has been appointed a Surgeon to the Surgical Aid Society, vice W. Allingham, F.R.C.S., who has been appointed Honorary Consulting Surgeon, and also a Member of the Committee.

KNAPP, E. M., M.R.C.S.E., has been appointed Assistant House-Surgeon to the Bristol General Hospital.

MASTERMAN, G. F., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer to the Astley District of the Martley Union.

NEWMARCH, B. J., M.R.C.S.E., has been appointed Senior Resident Medical Officer to the Royal Free Hospital.

PAGE, F., M.D., M.R.C.S.E., has been appointed Surgeon to the Newcastle-on-Tyne Infirmary, vice Heath, resigned.

PORTER, J., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Town and Port of Fleetwood.

POWELL, R. D., M.D., F.R.C.P.L., has been appointed Physician to the Middlesex Hospital.

PRITCHARD, E. J., M.B., C.M., L.S.A.L., has been appointed Medical Officer to the Wolvey District of the Hinckley Union.

ROBERTS, J., M.R.C.S.E., L.S.A.L., has been appointed Consulting Surgeon to the Cardiganshire Infirmary.

ROBERTSON, Mr. J. C., has been reappointed Senior Clinical Assistant to the Glasgow Hospital and Dispensary for Diseases of the Ear.

ROSS, J., M.D., C.M., has been appointed Medical Officer to the Higher Hawes District of the Aysgarth Union.

SEARLE, G. C., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for Lower Brixham. £20 per annum.

SMITH, R., M.B., C.M., has been appointed Assistant Physician to Charing-cross Hospital.

VERNEDE, Mr. F. E., has been appointed Medical Officer of Health for the Poole Urban Sanitary District, vice Lawton, whose term of appointment has expired.

WALKER, J. S., M.D., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health to the Local Board of Smallthorne.

WITCHFELL, Mr. G., has been appointed Medical Officer for the First "A" District of the Westminster Union.

Births, Marriages, and Deaths.

BIRTHS.

COOKE.—On the 6th inst., at Henley-on-Thames, the wife of J. Benson Cooke, L.R.C.P., L.R.C.S., prematurely, of a daughter (still-born).

COTTON.—On the 24th ult., at Abingdon-street, Northampton, the wife of George Cotton, M.R.C.S.E., of a daughter.

CROSS.—On the 1st inst., at Stanhope-terrace, Regent's-park, the wife of John Cross, M.D., of a daughter.

GURDON.—On the 31st ult., at Hopton, Thetford, the wife of Edwin J. Gurdon, L.R.C.P. Ed., of a son.

SKIMMING.—On the 8th inst., at Tudor Lodge, East Molesey, Surrey, the wife of Robert Skimming, M.D., F.R.C.S.E., of a son (still-born).

MARRIAGES.

BLAND—ROME.—On the 3rd inst., at St. John the Baptist's Church, Enderby, Leicestershire, William Charles Bland, M.R.C.S.E., of Milton, Southsea, Hants, to Emma, youngest daughter of the late Joseph Rome, of Groundslo, Staffordshire.

BRANDER—CLAY.—On the 23rd Sept., at Murree, Punjab, Edward Salisbury Brander, M.B., F.R.C.S.E., Surgeon, Bengal Medical Staff, second son of Colonel M. J. Brander, Bengal Staff Corps, to Minnie Edith, third daughter of Major-General E. Bertie Clay, late Bengal Staff Corps.

DICKSON—SHAW.—On the 3rd inst., at St. John's Church, Worksop, Edward Dalzel Dickson, M.D., M.R.C.P., Physician to the British Embassy, Constantinople, to Lucy Lillias Martha, youngest daughter of the late Charles Shaw, of Malta.

FOTHERGILL—HAMMERSLEY.—On the 4th inst., at St. Thomas's, Marylebone, J. Milner Fothergill, M.D., to Adelaide Beatrice, younger daughter of William H. Hammersley, Esq., of Bridge House, Staffordshire.

HUNTER—BLACKWOOD.—On the 10th inst., at Burnbank-terrace, Glasgow, Walter Hunter, M.B., C.M., of Nottingham, to Annie Pollock, youngest daughter of the late William Blackwood, Esq., of Glasgow, and niece of Dr. Pollock, of Springbank, Newton-Mearns, Renfrewshire, N.B.

DEATHS.

AITKEN.—On the 3rd inst., very suddenly, at Derby-terrace, Douglas, Isle of Man, William Aitken, M.D., Deputy Surgeon-General, Madras Army (Retired).

ANDERSON.—On the 7th inst., at York-place, Portman-square, Alexander Anderson, M.A., F.R.C.S. (by examination), in his 77th year.

BOOTH.—On the 3rd ult., at Barnfield House, Oswaldtwistle, John Booth, M.D., of Oswaldtwistle, Lancashire, aged 84.

CARRINGTON.—On the 29th ult., at Dunkeld, Athole, Forbes Carrington, M.D., of Dunkeld, and Sutherland-gardens, W.

GILES.—On the 23rd ult., at his residence, East India Dock-road, Limehouse, William Giles, M.D., aged 69.

MERYON.—At Chorges-street, Mayfair, Edward Meryon, M.D., F.R.C.P., aged 71.

WALKER.—On the 7th inst., at Netherwood-road, West Kensington-park, W., Henry Read Walker, M.R.C.S.E., third son of the late Sanderson Walker, M.D., of St. Michael's, Azores, in his 51st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

PUNCTURE WOUND OF KNEE-JOINT SUCCESSFULLY TREATED WITH COLD AFFUSION.

DR. A. H. NEWTH, of Hayward's Heath, sends us a record of the following case:—"Mr. T.—, while nailing a piece of wood to an upright support, which he steadied with his right knee, accidentally drove the nail into the joint to the extent of an inch. The wound was on the inner side just below the patella. There was intense pain both on movement and pressure around the joint. He was seen at once, and carbolic spray, with ether, applied for a short time. The joint was covered with lint dipped in weak carbolic-acid solution, occasionally renewed. Over this a stream of ice-cold water flowed constantly. The treatment was continued for four days. At the expiration of this time all inflammatory action had subsided, and, beyond a slight stiffness, the patient suffers no inconvenience."

Dr. W. H. Rollins, (Boston, U.S.A.)—The paper will appear in an early number.

MR. C. C. WHITEFOORD.

To the Editor of THE LANCET.

SIR,—On the 31st ult. a representative of the press reporting for the Coroner's Court in Central Middlesex called at my residence, and, expressing surprise at my continued existence, informed me that my name was on the coroner's list of inquests for the following day.

As various reports of my "death" had appeared in certain papers, I took the opportunity of retaining the services of my visitor to contradict the report generally, he undertaking to call upon and communicate with all the morning and evening papers, while I supplemented his action by writing autograph letters, acknowledgments of which I enclose for your perusal.

I have during the past week been the recipient of much correspondence and of many kind inquiries, and even of hysterics from hysterical subjects, and (to descend from the sublime to the ridiculous) of circulars from advertising undertakers and funeral contractors; but it was on the 6th inst. that I was interviewed by a gentleman about to establish himself in medical practice in London, whose attention had been called by a mutual friend to a notice of my death inserted in THE LANCET, and whose visit to me resulted from an inference being drawn that "a genuine bona-fide death-vacancy medical practice" would be "for disposal."

May I so far further encroach on your valuable space as to state that I have since my reported "death" attended three ladies of my *clientèle* in their accouchements, receiving from the husband of one, in addition to my fee, an honorarium of one guinea.

I remain, Sir, your obedient servant,

Albany-street, Nov. 8th, 1880. C. C. WHITEFOORD.

FISI-EATING AND LEPROSY.

The publication of several letters on the above subject is unavoidably postponed till next week.

H. A., (Liverpool).—The card is, of course, very objectionable; but no good purpose would be served by reproducing it in our pages.

E. H. M.—Application had better be made direct to the Secretary of the Senatus Academicus.

W. A. M.—We do not name particular physicians or surgeons.

THE DRAINAGE-TUBE IN PLEURITIC EFFUSION.

To the Editor of THE LANCET.

SIR,—May I make an addition to your report of the meeting of the Medical Society on the 1st inst.? I am reported to have said that my "plan was to insert a drainage-tube should the second tapping be followed by return of the effusion." I wish to add that this only applies to cases of empyema, as I would not advise the use of the drainage-tube so long as the fluid remains merely sero-fibrinous.

I am, Sir, faithfully yours,

Queen Anne-street, W., Nov. 1880.

F. DE HAVILLAND HALL.

BILE AS A PRESERVATIVE.

A WRITER in the Louisville *Medical Herald* offers the following remark on this subject:—"Five years ago I had for microscopical examination a sample of albuminous urine, which contained bile and large quantities of tube-casts and renal epithelium. The renal derivatives were so numerous and so beautifully coloured that a drop of the sediment was placed on a slide and covered—a ring of cement run round,—intending to use it as a temporary mount for class-demonstration. The casts &c. remain perfect to this date. Would not iodised serum to which a small quantity of bile has been added prove a good preservative and colouring agent for organised products of this kind?"

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—I am thankful to "A. G. P." for affording me an opportunity, by your favour, of supplying one or two omissions in my recent paper on the above subject. The question of multiple pregnancy to which he alludes was not treated by me, because I was anxious to avoid trespassing on your space to the extent necessary for a discussion of details. I cannot now venture to do more than indicate the data from which my general inferences are deduced. First, let me say that nothing is more unreasonable than to assume that multiple pregnancy and birth implies multiple conception. As a matter of fact, there is commonly an appreciable difference in the size and—though less obviously—in the development of children born at the same period, which seems to point to a difference in their actual age. This is nearly always noticeable when twin-children are of different sex. Meanwhile it is quite consistent with my interpretation of the law governing sex to suppose that the energy of the one parent may be called into action by the ardency of the other, and that the force which determines sex may, consequently, proceed first from one side and then from the other. At the same time I doubt whether well-authenticated cases of multiple pregnancy, with the birth of children of different sex, after a single conception exist. In the majority of instances twins are of the same sex, and generally female. My own total experience in midwifery, counting only cases in which I have noted the sex of the children, does not greatly exceed one thousand cases, an obviously insufficient number to go upon, considering the comparatively small proportion of twin births—little more than one per cent.—and the circumstance that I have only seen two cases of triplets; but I believe the statistics of obstetric practitioners will bear out my conclusion. I will not do more than throw out the query whether there is any instance on record of twins of different sex with a really single placenta? It would not upset my hypothesis if cases of this nature could be adduced; but I doubt if they can. The fusion of two ova is clearly possible, though independent development from two is more probable, and commonly occurs.

I should like to embrace this opportunity of supplementing my general statement as to transmission and heredity made in the paper which appeared in your columns on October 23rd, by saying that I most firmly believe in the communication of mental impressions by the female. In a paper on "Ideation in Utero," which you allowed me to place before your readers on Dec. 16th, 1876, I submitted that mental processes of thought and feeling taking place in the mother during pregnancy affect the child, probably by impressing the molecules of the fetal cerebrum, by way of nutrition through the maternal blood. I am more than ever convinced of the accuracy and practical importance of that hypothesis. I will now add that the reproduction of characteristics resembling those of the father in the son is in a large measure effected through the agency of the female. Where there is strong affection on the part of the mother for her husband, his likeness, physical and mental, is as it were impressed on his son through the agency of the mother's psychic force—to use a term which stands for, rather than expresses, an unknown potentiality: a force which undoubtedly exists, although we cannot define it, and which plays a prominent part in the propagation of the species. This is a consideration which should be recognised; it explains many of those "exceptions" which actually prove, though they seem to detract from the authority of, the rule. The "feeling," impulse, or sentiment which pervades the mind of the mother does certainly control or influence the development of the child. Peculiarities of feature and form that impress her powerfully, whether with admiration or abhorrence, are therefore likely to be reproduced in her offspring; and if her mental conceptions are peculiarly strong, the impression may be transmitted in exaggerated intensity. The same result will thus follow the working of love or fear. These things happen commonly in the case of the male child, which is in a special sense the mother's. The likeness which female children bear to their male parents is the direct effect of reproduction in kind. The maternal influences are less evident in a female than in a male offspring.

The practical bearings of this subject are obvious. First, the probable influence of intention in the determination of sex is in itself of moment to the happiness of families and the good of the community. Second, there is the opportunity offered of suppressing, and perhaps progressively extinguishing, hereditary disease, by the selection of a sex unfavourable to the development of such disease.

Yours obediently,

Welbeck-street, Nov. 1880.

JOSEPH MORTIMER GRANVILLE.

M.B., being a private practitioner, and in no way connected with the Poor-law authorities, is, we think, entitled to his guinea for examining a supposed lunatic and certifying. A letter should be addressed to the Clerk of the Board of Guardians, and failing a satisfactory reply, application should be made to the Secretary of the Local Government Board, Whitehall.

Mr. Roberts, (Buckhurst Hill.)—We deem it inexpedient, as a rule, to comment on newspaper reports.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION AT BRISTOL.

To the Editor of THE LANCET.

SIR,—Your correspondent, "Temperance," is somewhat unfortunate in his attempt to show "the utter untrustworthiness of the statistics set forth to show the advantage of total abstinence over even temperance," seeing that those to which he refers are perfectly correct. I may be allowed to explain, for the benefit of your readers, that these and other like facts were embodied in a paper which I had the honour of reading last month at a meeting of medical men in Bristol, which paper has been printed by the National Temperance League, 337, Strand, W.C., under the title, "What shall Medical Men say about Alcoholic Beverages?" price 1d. Anyone interested can see in that paper the figures in question, with several others. I derive no profit from its sale.

As the matter is of far deeper importance than the mere establishment of my *bona fides*, I should be glad of the opportunity of showing the error into which "Temperance" has fallen through imperfect knowledge. If he will refer to Parke's Practical Hygiene, first edition, p. 469, he will find the following table of the mortality among the adult male population from 16 to 70 (all but an insignificant number of those in benefit clubs are between these ages):—From 16 to 20, '730 per cent.; 21 to 30, '974 per cent.; 31 to 40, 1,110 per cent.; 41 to 50, 1,452 per cent.; 51 to 60, 2,254 per cent.; and 61 to 70, 4,259 per cent. The average mortality from 16 to 70 being, therefore, 17.94 per 1000, or 1 in 55. If the ages 16 to 60 be taken (and this will probably include 90 per cent. of the members), then the average mortality is 13.02 per 1000, or 1 in 76. When it is recollected, further, that the members of benefit clubs are picked men, it need not be a matter of surprise that there should be in a certain club a mortality of 9.9 per 1000 in the course of ten years, and in another, during eight years, of 7.09 per 1000, or 1 in 141.

It should be remembered, also, that in all benefit clubs a certain number lapse from membership from various causes as time goes on, and when their increasing age would raise the average mortality; on the other hand, there are always young healthy men coming in to lower the mortality. Any difference, however, in the mortality of two clubs in which all the conditions, except as to their drink, are the same, will enable us to ascertain what influence alcoholic liquors exert. Even if the whole difference may not be due to one cause, yet I think there is sufficient evidence to show that the tendency of alcoholic liquors is to injure health and shorten life, and this conclusion becomes enormously strengthened by the multiplication of instances in which a low death-rate is coincident with total abstinence, and still more when this is found in every case where sufficient numbers and time are taken.

There is further confirmation of this kind beyond that previously given. I have before me the last three annual reports of the National Division of the Sons of Temperance for 1878-80 inclusive. The average membership was 14,028, and the deaths of members in these years were 97, 120, and 129, average 115—that is, 8.2 per 1000, or 1 in 121. Moreover, we have Government statistics respecting our soldiers. Dr. W. B. Carpenter long ago published the Government returns of the mortality in the Madras army in 1847, in which the deaths of intemperate soldiers were 44.58 per 1000; of the temperate, 23.15 per 1000; and of the abstainers, 11.11 per 1000. Allowing for difference of climate, this mortality of 1 in 90 is parallel with the other instances.

In a few months there will be published the first quinquennial report of all Friendly Societies registered under the Friendly Societies Act, in which all the statistics will be strictly comparable, and in which the average age of the members in each Society will be given. This last item of information is the only unknown point about the statistics I have given; but it is highly improbable that there is any such great difference between the abstaining and non-abstaining Societies in this respect as greatly to alter their relative position, and it may be confidently expected that the returns, when published, will clearly demonstrate the immense superiority, as regards health and longevity, of a total-abstaining over a non-abstaining community.

I am, Sir, yours obediently,

J. JAMES RIDGE,

Hon. Sec., British Medical Temperance Association.

Enfield, November, 1880.

Surgeon.—The inquiry is too vague to allow of a specific reply. There is no book issued with the title mentioned.

Dr. G. Harley is thanked.

BRONCHITIS COMPLICATED WITH DIARRHŒA.

To the Editor of THE LANCET.

SIR,—I not unfrequently meet with cases of acute bronchitis complicated with severe diarrhœa in teething children. I should be thankful if any of your readers would favour me with an effectual prescription for this formidable combination.

Yours faithfully,

ALFRED BERNARD, M.R.C.S.

Queen's-road, Upton-park, Nov. 8th, 1880.

TIME AS AN ELEMENT IN THE APPRECIATION OF MEDICAL SERVICES.

THE following significant story by a Dakota Territory medical practitioner is taken from the *Michigan Medical News*:—

"I was called at midnight to see a gentleman who had just returned from a late dinner, where, in hasty eating, he had lodged a large fishbone in his throat. I provided myself with an emetic, cesophagus forceps, and other paraphernalia designed to give him relief, and hurried off to him. I found him pacing up and down, with a look of intense distress and anxiety, occasionally running his fingers down his throat, and gagging. He told me in tones of despair that he thought it was all up with him, but begged me, if the least glimmer of hope remained, to proceed at once in my efforts to relieve him. He extravagantly declared that he would give a million dollars to have that fishbone removed. I assured him that such cases were frequent, and ordinarily not attended with much danger, before proceeding to carry out measures for his relief. His fears underwent some diminution on the strength of this, and he then declared that fifty thousand dollars would no more than repay the skill and art required to extricate the unwelcome intruder. I smiled, and proceeded to introduce the forceps, but after several efforts failed to grasp the bone. His fears again induced him to mention a fabulous sum as the meed of the service that would expel the object of his terrors. I then gave him the emetic; its depressing effects causing his generosity to rise again, barometer-like, to a very high pressure. In a little while the emetic disburdened him of the greater part of his dinner, and with it up came the fishbone. He gave a sigh and look of relief, and, solemnly looking toward me, said, 'Doctor, I would not have that thing in my throat again for five dollars!' My fee eventually resolved itself into the 'valuable experience' that the occasion afforded me."

Post-mortem.—If the friends distinctly refused their assent, such a proceeding is undoubtedly illegal; at the same time we question whether another practitioner should advise or initiate any proceedings in the case.

Mr. Woods.—We think the remonstrances might well have elicited a courteous reply; but the matter is not worth troubling about.

WE have received from St. John's, Antigua, a communication dated Oct. 25th, 1880, without a signature.

Mr. W. H. Folker.—We are not aware of the source of the statement quoted.

Mr. James Hawkins is thanked for his letter.

"FEVER" STATISTICS IN MADRAS.

To the Editor of THE LANCET.

SIR,—A few days ago I had an opportunity of seeing the Memorandum of the Army Sanitary Commission on the Health Returns of British Troops in Madras for 1878. With your permission I desire to make a few remarks thereon.

It appears to me that the value of the Memorandum is seriously diminished by the unsatisfactory statistics upon which it is based, and that there were good grounds for supposing, as I shall presently show, that there "has not been such an advance in the sanitary improvement of several of the stations as might have been expected."

In the Army Medical Department Report for Madras separate statistics for the several diseases constituting the group of "continued fevers" are not given; but seeing that only three diseases of this group—simple continued fever, febricula, and enteric fever—are mentioned in the Report, and that it is recorded that there were seven admissions for enteric fever, it follows that, after deducting these seven, the admissions for simple continued fever and febricula were 1935, or more than one-half of the total admissions (3812) for all diseases of the febrile group. Contrast this with the Bengal Presidency, in which the admissions for simple continued fever and febricula were about one-fourth, or 6434 out of 23,608; and with Bombay, in which the admissions for these two diseases were less than one-seventh, or were only 1274 of the total (8935) for the febrile group.

When contrasting Madras with the other Presidencies in respect to the occurrence of enteric fever, it is curious to observe the almost complete absence—only seven cases—of enteric fever from the disease returns of the Madras army. This seeming immunity can, I think, be very satisfactorily accounted for, as will be explained further on.

The longer I remain in India, and the more opportunities I have of observation, I am becoming more convinced that the indiscriminate use of the classification "simple continued fever" is open to grave objection. I have known where more than one-half of the admissions for all fevers were recorded as simple continued fever, and where on change of medical officers such name of a disease ceased to appear. I have also known the most malignant and fatal disease recorded as simple continued fever. This is a matter within the knowledge of Dr. Gordon.

I merely give these instances to show the laxity with which the designation is used. Instead of being a "refuge for cases of an uncertain character," I look upon the employment of the name "simple continued fever" as an indication, in the majority of cases, of an inexact and careless diagnosis. I have seen this name so often misused that I should be very much inclined to abolish it altogether from the Army Returns by the same means as Dr. Gordon so successfully used in

respect to enteric fever in the Madras command—that is, by issuing endless and perplexing memoranda and circulars of directions, and calling for so many special reports as to make it almost impossible for a medical officer to record a case as enteric fever.

As regards the small number of cases—only seven—of enteric fever, it appears to me that the "very decided reduction" of Dr. Gordon can be very easily accounted for, and also the fact that the disease is only recorded as having occurred at two stations (Secunderabad and Kamptee) in the Madras command. What seems to me strange is that in the face of almost overwhelming opposition and difficulties any cases were recorded at all.

In order that you may form some conception of the difficulties and obstructions to be surmounted, I may mention that during 1878 Dr. Gordon issued eight circulars of directions to medical officers, covering eight and a quarter closely printed pages, on the subject of enteric fever; two of these were republications of circulars issued in 1876-77. The first required the medical officer in charge to institute a full and searching investigation into the history of the case, the direction of the investigation being indicated under six headings, with several sub-headings. In this circular the printed directions alone covered two pages, with the exception of eight lines, and the special report was required *in duplicate*; this was afterwards changed to a single copy. In March another circular, with further directions, was issued. In July a circular of five paragraphs and several minor headings appeared with reference to the report on the eruption, and directed medical officers to "record precisely" what was required under the various headings. In August there were two circulars of further orders; one of these embraced twenty-two printed headings, and ordered that *in every case* considered as of enteric fever a return made out in "strict accordance" should be forwarded immediately on the termination of the case in recovery or death. In September two more circulars were issued. It might now be supposed that the climax was reached, but such was not the case. Early in the following January, 1879, another circular appeared, directing medical officers in future to furnish with their "special reports" a transcript from the case-book and a temperature chart. When it is taken into consideration that copies of all these special reports, &c. &c., have to be kept in the hospital books, and when it is considered how much time, worry, and unnecessary labour are involved in recording a single case of enteric fever, and that to comply with all the complicated instructions would almost fully occupy a medical officer's whole time, it will be easily understood how it is that enteric fever has practically ceased in the returns of the Madras army. I have been told by an officer of long standing that as long as Dr. Gordon was in Madras he would never record a case in his hospital as enteric fever. The statistics go far to prove that others were acting likewise.

It is earnestly to be hoped that the present enlightened administrator who is in charge of the health of the Madras army will, in the interests of the service, take an early opportunity of annulling such regulations. I look upon them as injurious in many ways. They render statistics valueless by practically preventing medical officers from recording diseases according to their knowledge and judgment, and they may be mischievous by tending to the absence of all those precautions which would otherwise be required to prevent the spread of infectious disease.

It is asserted that at no station in the Madras Presidency are there any *filth* causes capable of predisposing to enteric fever; but the Sanitary Commission (page 6) very wisely say that on this point other proof is required than mere assertion. I have served in the four divisions of the world, and I can honestly affirm that I have never seen *filth* approaching in any degree to what I have seen in the Madras Presidency. I can point out stations where the dry-earth system was not in existence, and where the air in the barrack-rooms was polluted by the effluvium from the exposed excreta. I can go further and point out where the ground was polluted by the burial of excreta in the immediate vicinity of the barracks. Years hence, when wells are sunk, as is not unlikely, in these very spots, the past history, if known, would account for any outbreak of disease that might otherwise appear obscure. I can also point out where collections of ordure were within one hundred yards of the barracks where a large European force was stationed. I have myself seen two cartloads of fresh human ordure, the stench in the neighbourhood being overpowering; yet with the existence of these, which are simple, unvarnished facts, to say that there are no *filth* causes is to me incomprehensible.

As regards the water-supply, I am pleased to see (page 9) that the Sanitary Commission do not accept its asserted purity. I have seen stations where the water-supply was most disgusting. It has often appeared to me that the difficulty of getting pure drinking-water was one of the chief causes of drunkenness in the army. This cause operates more in India than elsewhere, and, I believe, drives men to visit the canteen. I have no hesitation in saying that the attention given to the purity of the water, as far as I have had opportunities of judging, is, as a rule, wholly insufficient. I could point out where wells supplying troops are in the hollow at the sides of the public road, where the drainage of the locality passes in their vicinity, and where they are used in common by the native civil population. I could also point out where the most foul impurities existed beside them—at one station heaps of animal and vegetable filth, at another station one of the principal wells had within about thirty yards of it a large tree growing; under this tree, on the higher ground at the side of the hill, was the place where the filth carts of the station were deposited when not employed removing the night soil. I have seen the surface water running in, and no adequate protection from pollution.

I am, Sir, yours faithfully,

Sept. 17th, 1880.

Lectures ON

THE RELATIONS OF SARCOMA TO CARCINOMA.

Delivered at the Royal College of Surgeons in June, 1880,

By HENRY TRENTHAM BUTLIN, F.R.C.S.,

ERASMUS WILSON PROFESSOR OF PATHOLOGY TO THE COLLEGE,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, &c.

LECTURE III.—PART I. CENTRAL TUMOURS OF BONE.

MR. PRESIDENT AND GENTLEMEN,—Most of the central tumours of bone may be included in one or other of the three groups in which in my last lecture the subperiosteal sarcomas were arranged—namely, round-celled, spindle-celled, and mixed-celled. But to these three must be added a fourth group, comprising the myeloid or giant-celled sarcomas. As I am not inclined to admit many of the tumours which are now included as myeloid, I will define as clearly as I can the meaning I desire to attach to the term Myeloid Sarcoma, but it may be well before doing so to discuss for a moment the giant-cell. This body may be described as a mass of protoplasm, usually of large size, flattened, and containing from two or three to many nuclei. Its form may vary considerably; so may the number of its nuclei; but large size and many nuclei are its characteristic features. Such cells may occur not only in central but in subperiosteal tumours, especially in close proximity to the bone. Such cells may occur, too, in tumours of the soft parts wholly unconnected with the bones, or may be found among the products of certain inflammations, especially those of bone. Many theories of their origin and nature have therefore been evolved, but the consideration of them need not long detain us here, for we are not concerned with these cells in the abstract, but with them only as they form the main part of certain tumours—I might perhaps say of certain tumours of bone of central origin, for I think I am within the truth in saying that such cells as these never occur in numbers so large as to form the bulk of a tumour of the soft parts, or even of a subperiosteal tumour. Their presence in such quantity in sarcomas of central origin may be explained on the theory that they are derived from the remains or still-existing germs of the many-nucleated cells of foetal marrow, or on the theory that they are connected with the destruction of the bone, which invariably occurs during the growth of central tumours. Whether they are the agents by which that destruction has been accomplished, or are mere accidental products formed during or as the result of such destruction, it is not more needful for us to discuss than it would be to discuss the exact origin of the round or spindle or mixed forms of cells, of which all sarcomas are for the most part composed. I may, however, point out certain facts connected with their occurrence in tumours of bone, and certain deductions which may be drawn from those facts.

First: they may form as much as four-fifths of a central tumour, but never comprise its whole bulk, for with them are always mingled round or more often spindle cells.

Second: a tumour which has grown far beyond the limits of the bone in which it took its origin may still be composed four-fifths of giant-cells.

Third: a tumour of central origin may contain no giant-cells, but may be formed solely of round or spindle cells.

Fourth: they are not of equal occurrence in the tumours of all bones, but exhibit a marked predilection for certain bones; the lower jaw, the femur and the tibia above all others, and even for certain parts of these bones, as the lower extremity of the femur and upper extremity of the tibia.

Fifth: a tumour which contains them in great abundance exhibits a maroon or dark-red colour, or a fleshy colour and appearance, likened by Sir James Paget¹ to that of the

muscular substance of the mammalian heart and peculiar to these and no other tumours.

From these facts it may be fairly argued—First: that the growth of giant-cells, and perhaps their origin, may occur independently of the destruction of bone. Second: that the development of giant-cells does not necessarily accompany bone-destruction, or if it does, the cells must sometimes disappear with startling rapidity. Third: that the conditions of their existence and of their growth, perhaps even their origin, are largely determined, not merely, by the presence of bone, but by the presence of a certain kind or quality of bone, or by the conditions of life existing in certain bones. Fourth: that the typical colour and appearance of a myeloid tumour are due to the presence in it of a large number of giant-cells. Fifth: that the presence of a large number of these cells may be deduced from the colour and appearance of a tumour. For these and similar reasons tumours which are composed largely of giant-cells may be said to have established a just claim to be grouped apart from other growths, as myeloid or giant-celled sarcomas—myeloid in admission of the right established by thirty years of use; giant-celled in accordance with the nomenclature of the other groups of sarcoma; and, lastly, sarcoma because of their undoubted connective-tissue origin, and their part-composition of round or spindle cells. But in this group I shall include only those tumours which are so largely constituted of giant-cells that these cells produce a decided effect upon the appearance of the tumour; in other words, that they colour the tumour maroon or red. A few giant-cells scattered through the substance of a round or spindle tumour can scarcely be expected to affect its course or tendencies, and I can conceive no reason for classing such a tumour in accordance with these, its least abundant and probably least important elements.

The 63 cases of central sarcoma here collected include 20 round-celled, 18 spindle-celled, 9 mixed-celled, and 16 giant-celled. In 17 cases the femur was the affected bone; in 13 the tibia; the lower jaw in 11; the skull and ulna each in 4; the humerus in 3; fibula in 2; and, in a single instance each, 9 other bones. To these relative proportions I shall have to refer in the consideration of the tumours of certain bones, but for the bones of the extremities they are probably nearly correct.

For the better comparison of the central sarcomas it will be convenient to employ the same order and method as that which was adopted in the study of the tumours of subperiosteal origin, and to consider separately the tumours of each bone affected.

Those of the FEMUR are again more numerous than the tumours of any other bone, and include all four varieties: 5 round-celled, 4 spindle, 3 mixed, 5 myeloid.

The round-celled tumours occurred in patients from nineteen to fifty-five years old, in patients, therefore, for the most part much older than those who were the subjects of subperiosteal round-celled tumours. They exhibited a similar tendency to attack the lower portion of the bone, for three of them were of the lower epiphysis and one of the lower portion of the shaft. One case, however, was of the upper epiphysis. It is related by Mr. Bryant in the Guy's Hospital Reports,² and is interesting on many accounts, for it differed as much from the round-celled tumours as from any of the other tumours of the femur. It was most rapid in its course, for although the patient died four days after resection, apparently from blood-poisoning, the disease was already widely generalised. This widespread generalisation is itself a point in which it differed from the rest as much in the manner as in the fact of its occurrence. For among the organs affected were the lymphatic glands, a circumstance so rare that in every case where it is noted I shall try with care to ascertain its cause. In this instance the enlargement of the inguinal glands was observed before the operation was performed. I imagine it was only slight enlargement, and was regarded rather as inflammatory than sarcomatous. But after the patient's death the lumbar glands were also found enlarged, and both the inguinal and lumbar glands were described as infiltrated. One of the latter was subjected to microscopical examination by Dr. Goodhart, who said it was an ordinary lymphatic gland with its cellular element predominating. It may therefore be maintained that the glandular enlargement was really of the nature of simple hypertrophy, or inflammatory, not directly connected with the tumour of the femur, but perhaps connected with

the blood-poisoning from which the patient died. I prefer, however, to regard the affection as secondary to the sarcoma, the round cells of which could not well be distinguished from those forming a lymphatic gland.

The explanation of the phenomenon lies probably in the infiltrating nature of the tumour, which spread along the ligamentum teres to the acetabulum, and in all directions into the surrounding muscles, the internal obturator, internal iliac, and even the adductors, from which it could gain easy access to one of the deeper femoral glands, and travel thence along the lymphatic channels. With the exception of this case these round-celled tumours were less malignant than the corresponding tumours of superficial origin. Their less malignancy is evidenced especially in the first and second cases. In the former, the tumour had existed eight years at the time of amputation, and even then there was no sign of its dissemination. In the latter the patient died from bronchitis and exhaustion at the end of nine months from the first appearance of the disease, which was shown by the autopsy to be still completely localised. A few bony spiculæ were present in this tumour, otherwise none of these round-celled growths was mixed with other form of tissue.

Two of the four cases of *spindle-celled* sarcoma are distinguished from the others by originating in the upper portion of the femur, and by their greater malignancy. One of them died from the effect of operation, a woman thirty-six years old, who, five months before her admission to the hospital, while walking quietly across her room, suddenly felt the right thigh crack two or three times. At the same instant the thigh became the seat of violent pain, and her progress was for the moment interrupted. From the time of this strange circumstance she suffered almost continuous pain, and soon a swelling was observed, which increased at first slowly, then with great rapidity. But for some time after the accident (if one may so speak of it) she was able to walk, although with difficulty and much pain, proving, I imagine, that the femur had not given way when it was felt and heard to crack, or at least that its continuity was not completely broken. Had there been a history of pain previous to the accident, or indeed even of discomfort in the thigh, and had there occurred with the cracking a spontaneous fracture of the bone, the occurrence would have been an illustration of what is not uncommon in tumours of central origin—namely,

of fracture as an early symptom of the existence of such disease. The tumour formed a smooth, almost hard, but yet elastic swelling of the right femur just below the great trochanter. The skin was not affected, and the glands were not enlarged. Amputation at the hip-joint was performed by Mr. Callender with complete success so far as concerned the removal of the growth, but a fortnight later the patient died with symptoms of pyæmia. The femur was fractured four inches below the upper end. The upper fragment was widened out and filled with a semi-transparent mass, looking and feeling like soft cartilage, in which were many cystoid cavities containing glairy fluid. The surrounding muscles for a short distance, and even the capsule of the hip, were infiltrated with the new growth, but the interior of the joint was intact. The microscope discovered cartilage of various forms, but for the most part cellular, a somewhat rare variety even in tumours. Around and even within the mass of cartilage was a quantity of round and spindle-celled tissue, which could scarcely be distinguished with the naked eye. All the tissues and organs of the body were free from the disease except the right lung, the lowest lobe of which contained one small nodule bearing similar characters to the primary tumour. I have given a rather longer account of this tumour because it is an example of what would, by many pathologists, be termed an enchondroma of the femur, and might therefore be employed to illustrate the occasional malignancy of a tumour made of cartilage. I have already given reasons for including these tumours among the sarcomas, and need now only draw attention to the rich mingling with the cartilage of spindle and other cells. In the other case generalisation was much more extensive, but the longer duration of the disease may help to explain the difference. The two features in this case which appear most to deserve attention are the tumour of the tibia of the same limb and the affection of certain of the lymphatic glands. The former is very rare, but I imagine this tumour bore the same relation to the tumour of the femur as do other secondary growths when the affection is conveyed through the medium of the blood. For it appeared late in the course of the disease, about the time we may presume the lungs and glands became diseased, and was nowhere continuous with the tumour of the femur. Of the relation which the affection of the glands bore to the original tumour I am not sure, but imagine they were affected

through the medium of the blood and not the lymph, for the femoral glands were not enlarged, those of the groin scarcely at all, while the glands in the pelvis and in one axilla are said to have been extensively diseased. If the disease of the pelvic and axillary glands was of the same nature, it is evident both sets of glands could not have been affected through the lymphatics from a single source. The last tumour of the sub-group contained cartilage, but only tiny islets scattered in its wall, for it was a large blood cyst, and contained only a small proportion of solid substance.

The sub-group of *mixed-celled* tumours contains little of marked interest, for two of the patients were not traced after their recovery from amputation, performed in each case early in the course of the disease, and the third patient died from the effect of the operation.

Of the *myeloid* tumours of the femur I shall not have much to say, but may point out that all five were unmixed with other tissues, and that neither of them grew into the surrounding soft parts, general statements which cannot be made of the other varieties of sarcoma. One case is distinguished by its fatal termination, and by the fact that it is the only one in which no operation was performed. Many features of its history and course are very characteristic not only of myeloid but of other central sarcomas of the femur. The first symptom was pain, which endured a month, when the femur gave way almost spontaneously. It was not till three or four months after the fracture that the presence of a tumour was observed. From that time, however, its growth was rapid, and five months later the patient died, as if worn out by the distress occasioned by the tumour, which yet was never very painful. The purely local nature of the disease was very singularly marked. It grew from the interior of the shaft about the junction of its middle and lower thirds—a rare position for myeloid sarcoma—destroyed the bone, and pushed aside the muscles, but did not involve them in its growth. Nowhere in the body was there any trace of dissemination of the tumour.

Two of the patients who had been amputated were seen, one sixteen months, the other three years, after the operations. Both were in good health.

Regarding now the characters common to most of these tumours of the femur, and comparing them, as, be it even unconsciously, we must do with those of the superficial growths, the most apparent and most important are their less fatal nature and often slower course. Of three patients it is recorded they were alive and well at periods respectively of nine months, sixteen months, and three years after operation. Only eight deaths are reported, and although this does not prove that the other patients are still alive, or remained free from sarcoma, the comparative mortality of this table, and of that of the subperiosteal sarcomas, is strikingly to the disadvantage of the latter. Even of these eight deaths three were due to causes directly connected with the operation. Indeed, five might be said to have so died, but I prefer to regard two of them as deaths from generalisation of the tumour, which was present in both cases. Extensive generalisation was very rare, while, on the other hand, two patients on whom no operation was performed, and whose disease pursued what may be regarded as its natural course, were free from secondary tumours.

I have already spoken of the rare occurrence of affection of the glands, but may here draw attention to the fact that the only tumours with which was associated enlargement of the glands were both of the upper portion of the femur. When I mentioned a moment since the slower course of these central tumours, I had no intention of implying that every case was characterised by long duration, but merely that long duration was a not infrequent character, and as proofs of this I may cite Nos. 1, 9, and several of the cases of myeloid sarcoma. Another noticeable feature in this group of tumours is the comparative simplicity of the tissues of which the tumours were composed, for if we exclude two, in which small spiculae of bone were scattered through their substance, there remain only two the soft substance of which was mixed with cartilage, and even in one of these the proportion of cartilage was scarcely more than microscopic. How far the relation of the periosteum to the subperiosteal growths causes the formation in them of bone and cartilage is difficult to estimate, but its influence is probably not small. Ofttimes the position of the periosteum is indicated through them by a line of bone or earthy salts. The strong disposition exhibited by central tumours to attack the lower epiphysis, or the lower third, is very ap-

parent. Lastly, many of the patients were older than those who suffered from subperiosteal tumours, the range of age extending from thirteen to fifty-seven years, instead of from nine to forty-one; while the distribution of cases among the decades was pretty equal.

It is peculiarly unfortunate that, although there were five deaths of persons suffering from tumours of the TIBIA, there was not in one case a post-mortem examination. For this reason the series is far less complete than could be desired. Yet there are certain characters which can be clearly read, and are too important to be overlooked. The scale of ages commenced at eighteen, and ceased at sixty-five—a point of difference from the tumours of the femur which might be regarded as accidental were there not a similar relative difference in the cases of subperiosteal tumours of the two bones. The absence of earthy salts or cartilage was as conspicuous in the tumours of the tibia as in the tumours of the femur. With perhaps one exception, the relation which these tumours bore to the tumours of the femur is similar to that which existed between the superficial tumours of the same bones. The exception was the rarity of ulceration of the integument covering the tumours of central origin, which probably was partly due to their slower growth and the efficient protection afforded by the bony or fibrous capsule by which they were surrounded. The points of accordance were the slightly more advanced age, to which I have already alluded, the position of the growth, the longer duration of the cases, and the complete absence of recurrence in the stump and of affection of the glands. The upper epiphysis or upper end was even more frequently the seat of central than of subperiosteal growths; indeed, all of them, save two, were of the upper epiphysis. Their long duration is exhibited in the column of duration to the period of operation, in the column of complete durations, and in the last column, where a statement is appended of the condition of those who were traced long after operation. The first of these columns shows that from one to two, or even more, years not uncommonly elapsed before amputation was performed. The second column shows that only one of the recorded deaths took place within two years of the first appearance of the tumour, and even this was due to causes connected with the operation. In the final column the good health of two patients is recorded, one five years and a half, the other a year, after operation. The two patients who died from causes not connected with the operation died in each case from some affection of the lungs, the nature of which could not be ascertained. Freedom from recurrence in the stump can be stated with certainty only of a few cases, but absence of glandular affection—that is, of affection of the femoral and inguinal lymphatic glands—can be unhesitatingly affirmed of many of them.

Before we leave the tumours of the tibia, let me draw attention to a feature of the disease well worthy of notice. This tumour, a growth of large size, is limited by a fibrous envelope on all sides, except towards the knee, where the cartilage, thinned and more cupped than usual, but still intact, intervenes to protect the joint. This is a prevailing character, not only of tumours of the tibia, but of tumours of the articular extremities of all long bones. The articular cartilage possesses a singular power of resistance or incapacity for contagion, differing in a striking manner from even the hardest bone in this respect. Long after the bone has been destroyed and the fibrous tunic is broken through, the cartilage maintains its integrity, only yielding at length, in a few rare instances, to the boring force of vertical columns of cells projected from the tumour and penetrating it through a series of fine pores. The calcifying sarcoma, No. 20, destroyed the joint, and produced ankylosis by following the unusual course of infiltrating the crucial ligaments and spreading thus from the tibia to the femur.

NEW HOSPITAL IN ST. PETERSBURG.—The Community of St. George, as a memorial of the first decade of its existence, has laid the foundation of a new hospital, which it proposes to establish on the banks of the Neva in St. Petersburg. The cost of the building is estimated at eighty-five thousand roubles. The site which has been purchased is occupied by the ancient palace of the Empress Anne, which modified as required, is to be included in the new structure. The hospital, when completed, will consist of four sections, each containing fifty beds. The wards will be on the first floor, the ground floor being devoted to the administration, stores, &c.

ON CATARRH OF THE STOMACH IN CHILDREN.

By EUSTACE SMITH, M.D., F.R.C.P.,

PHYSICIAN TO H.M. THE KING OF THE BELGIANS, PHYSICIAN TO THE EAST LONDON CHILDREN'S HOSPITAL AND TO THE VICTORIA PARK HOSPITAL FOR DISEASES OF THE CHEST.

THE susceptibility in early life to catarrhal disorders, and the variety of derangements which may be induced in children by exposure to cold, have often been the subject of remark. In childhood the mucous membrane is especially liable to be affected by chills, but the "cold" does not always show itself in the form of sore-throat or cough. In babies and young children gastro-intestinal disorders are perhaps the most common derangements set up by changes of temperature; and in older children, and even in adults, a gastric or intestinal catarrh, or a combination of both, is a sufficiently familiar consequence of exposure to cold. In the child we meet with every variety of gastric catarrh, from the severe acute attack with high fever, which is comparatively rare, to the more common subacute non-febrile gastric derangement, which is milder in character and quickly subsides. Even in children it is exceptional for acute gastric catarrh to be accompanied by pyrexia; therefore in cases where fever is a prominent feature in the derangement the diagnosis is sometimes difficult. The following case, which was seen in consultation with Dr. Günther of Hampton Wick, affords a good illustration of this variety of gastric catarrh.

Miss C. K—, aged six years, had been delicate and subject to occasional failure of appetite for some months. For about a week she had been feverish, the bodily temperature rising sometimes as high as 104° Fahr. Her appetite had been completely lost, but she had not suffered from sickness. The bowels, at first sluggish, had been somewhat relaxed for two days, the motions passed being moderate in quantity, but loose, rather offensive, and bright yellow in colour. She had occasionally complained of abdominal pains. During the whole time of her illness the child had snuffled slightly, and at first her throat had been a little sore, but there had been no cough. She had complained sometimes of frontal headache, but had not been delirious.

At my visit I found the child lying in bed, with her face turned away from the window, as the light, she said, hurt her eyes. There was no sallowness of complexion. Her expression was placid, and not at all anxious or distressed. The tongue was a little furred on the dorsum, and rather red at the tip and edges. She was thirsty, but had no desire for food. The abdomen was soft, without tenderness or distension. The spleen was very indistinctly felt; it seemed to be slightly enlarged. There was no rash of any kind on the body, nor any oedema of the legs. The urine was not albuminous. The heart-sounds were healthy. There was no rhonchus or other abnormal sign about the lungs. Respiration regular, 24; pulse regular, 108; temperature 101° F. (at 4 P.M.)

This case, which was seen on the seventh or eighth day of the illness, when the ordinary eruptive fevers could be excluded, might have been acute tuberculosis, typhoid fever, or acute gastric catarrh. The occurrence of fever, with a history of previous delicacy of health, was quite in keeping with the ordinary course of tuberculosis. There was, however, no family history of any such complaint, and this important fact, together with the complete absence of distress or anxiety in the expression of the child, and the absence, also, of any oedema of the lower extremities, was held sufficient evidence to exclude the presence of this formidable disease.

Between typhoid fever and acute gastric catarrh the distinction was more difficult. The temperature, it is true, although always elevated, had not followed the course of the temperature in a typical case of enteric fever; but in children this fever is often mild, and frequently deviates from the ordinary type. Again, the absence of eruption did not exclude typhoid fever, for the eighth day is early for the rash to appear, and in children typhoid spots are sometimes absent altogether in undoubted cases of the disease. On the other hand, the state of the spleen was doubtful.

Some slight enlargement was suspected; if so, the fact pointed distinctly to typhoid fever.

In favour of acute gastric catarrh was the slight snuffling, the mild sore-throat, the complete absence of delirium, or of apparent discomfort, and the irregularity of the fever. Altogether, the symptoms pointed, perhaps, more decidedly to gastric catarrh than to the more serious disease, but it was impossible positively to exclude typhoid fever, and therefore a guarded opinion was expressed as to the nature of the case. The temperature fell on the following (eighth or ninth) day, deciding the question in favour of catarrh; for typhoid fever, even in its mildest form, does not subside before the fourteenth day.

When gastric catarrh, instead of occurring in one solitary attack, as in the above instance, recurs repeatedly at short intervals, the diagnosis is more easy. Cases of recurring gastric catarrh of greater or less severity are far from uncommon; and these attacks, if the intervals between them are short, may exercise a very injurious influence upon the health and general development of the patient. Children the subjects of such catarrhs become pale and thin, for their nutrition is being constantly interrupted. By its influence upon appetite and digestion the catarrh checks for the time the introduction of nourishment into the system, and nutrition is hardly restored on the cessation of the attack when a return of the derangement suspends it again as before. In this way the child may become an almost constant sufferer from disordered stomach, and his continued ill health and persistent wasting excite the gravest apprehensions amongst his relatives. Such cases are often supposed to be cases of consumption; and, indeed, if there be any inherited chest weakness, long-continued interference with nutrition, such as is produced by a frequent recurrence of these attacks, may go far to encourage the tendency to phthisis.

The recurrent form of acute febrile gastric catarrh is well illustrated by the following case, which I saw with Dr. Lister of Croydon. The patient, a little girl aged seven years, was pale and short for her age. She had been wasting slowly for eighteen months. During the whole of this time she had suffered every two or three weeks from attacks of feverishness. In these illnesses the general symptoms were the same. The temperature rose to 103° and 104° F. The child looked sallow in the face, and was very irritable and languid. She was thirsty, but refused her food. Sometimes she vomited, but in the earlier attacks the bowels were never relaxed. She got thinner and weaker, and looked ill. A few months previously she had had a severe attack at Lowestoft, in which she had been slightly jaundiced. Six weeks before her visit to me she had a still more violent attack, which had left her completely jaundiced. This had been followed, for the first time in her experience, by diarrhoea, and for a fortnight the motions were green and slimy, and sometimes contained clots of blood. They were passed with straining and some pain. At the time of her visit the looseness had in a great measure subsided, but the child still had a faint yellow tint of the skin. Her heart and lungs were healthy, and there was no sign of enlargement of her bronchial glands. Between the attacks of illness the child was said, as a rule, to be fairly well. On the subsidence of the fever her appetite would return; and she would begin to regain flesh. Unfortunately, before her strength could be said to be thoroughly restored, it would be again reduced by a fresh access of fever.

Jaundice in children, in the large majority of cases, is catarrhal. In this child its occurrence with the two last attacks of fever helped greatly to explain the nature of these attacks, and the cause of the continued ill-health from which the child was suffering. Besides, in the most recent illness a new feature had been noticed in the diarrhoea which had followed upon the jaundice, and had still further delayed convalescence. In this diarrhoea the characters of the stools, which contained mucus and blood, and were passed with straining and pain, pointed to a catarrh of the lower bowel. Explaining, then, the earlier attacks in the light afforded by the later, we were enabled to arrive at the conclusion that the child's sensitiveness to changes of temperature showed itself in the form of repeated attacks of acute gastric catarrh, accompanied by fever. This fact being once established the treatment of the case was conducted upon the principles to be afterwards described, and the child had no return of her feverish symptoms.

A very similar case of recurrent febrile gastric catarrh was sent to me by Dr. Royston.

Edward A.—, aged seven years, “has all his life been subject to feverish attacks. These have been more frequent since he had measles in the spring. The attacks come on every five or six weeks. They are preceded by stammering and twitching, and are always followed by sore-throat. During the illnesses the child coughs a little, looks sallow, is very dark under the eyes, and complains of pain on the top of his head. He refuses food, but is very thirsty. Lately he has been sick at these times; formerly he used to have diarrhoea. The boy is rather stout for his age. He appears to be suffering from these repeated attacks, for he is not so strong as he was. He is irritable and subject to fits of crying. Has rather a sallow complexion. Heart and lungs quite healthy. Liver and spleen of normal size.”

(To be concluded.)

TWO CASES OF FRACTURE OF THE SKULL, IN ONE OF WHICH TREPHINING WAS FOLLOWED BY COMPLETE RECOVERY.

By RICKMAN J. GODLEE, M.S., F.R.C.S.,
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

EXAMPLES of successful trephining are so comparatively uncommon, and the indications for performing the operation so obscure, that it seems right to put the following two cases on record: one in which a complete recovery followed the operation, and another in which, owing to the difficulties of diagnosis, the patient was allowed to die unrelieved.

CASE 1.—F. McC—, aged twenty-three, on July 28th of the present year was spending his evening at a gymnasium, when he accidentally got in the way of a sixteen-pound shot, which was being put by one of his companions. The shot struck him on the right side of the head, above the temple, knocking him down and producing a slight wound. The patient was carried to the next room, and then taken in a cab to University College Hospital, both of which facts he afterwards clearly recollected, but beyond this point his memory became a blank. He distinctly remembered making objections to being brought to the hospital, because he thought his mother would be very anxious about him. On his admission about 9.15 P.M., he walked from the cab into the casualty room, and when examined by the house-surgeon was found to be quite conscious, answering questions rationally but slowly, and expressing himself as feeling dazed. There was a small punctured wound of the scalp on the right side, three inches above the zygoma, and two inches behind the external angular process of the frontal bone. A distinct ridge corresponding to a depressed fracture was to be felt passing across the wound, there being at this time but little extravasation of blood into the tissues. He vomited once before he was taken to the ward, and at this time his pulse was 60 and his respiration 30. Three-quarters of an hour later, at 10.30 P.M., he was very drowsy, but still conscious when roused, though the rousing was a matter of some difficulty. The pupils were then equal, but the grasp of the left hand was weaker than that of the right. The respirations were slow and shallow, the pulse a little under 60. Very soon after this he was seized with a violent clonic spasm of both sides of the body, that on the right side being, however, much more marked than that on the left, and the left side of the face being almost unaffected. There was no deviation of the eyes; the pupils were widely dilated. The spasm was so violent that the patient almost rolled out of bed, and at the same time he became markedly cyanotic. During the spasm the pulse became rapid, reaching 112, but it soon dropped to 70 or 80. This attack was followed by others of a similar character, but of shorter duration, in the intervals of which he lay quite unconscious, groaning and turning restlessly in bed, resisting attempts to examine or move him, with his respiration considerably impeded, and occasionally quite stertorous. He was in this condition when I first saw him, and thus although, owing to the effusion of blood into the tissues of the scalp, it was now impossible to feel the depression, the gradual but rapid onset of the symptoms, the present state of complete unconsciousness, the weakness of the left side, and the stertorous

breathing, determined me to cut down at once on the seat of injury.

It was necessary to anaesthetise the patient on account of his struggling. When he was under the influence of chloroform a crucial incision was made at the seat of injury, and after raising the periosteum with the flaps, it was seen that a fracture existed in the parietal bone, which ran forwards and inwards towards the coronal suture. The bone in front of, or outside the fissure was splintered and depressed about an eighth of an inch, and blood was escaping freely through the crack. I at once applied a large trephine, and removed a circle of bone, including as much as possible of the depressed portion. The inner table was more splintered than the outer, and the loose pieces had to be taken out with forceps and an elevator. When the hole was cleaned, it was found that the dura mater was intact, but separated very widely from the bone, so that a probe could be passed beneath the latter for nearly its whole length in the direction of the forehead; the interval between the dura mater and bone being occupied by fluid blood, which welled up freely. The anterior branch of the middle meningeal artery passed across the middle of the trephine hole, and it was clear that the bleeding was occurring from one of the accompanying veins, which was lacerated. I was puzzled at first in trying to arrest this hæmorrhage; the endeavour to pass a small needle beneath it, armed with fine catgut, resulted only in pricking the vein again; but on seizing the bleeding point with a pair of catch-forceps, and tying in the usual way, the ligature held, and all bleeding stopped at once. The wound was brought together with silver sutures, and a small drainage-tube was placed in it; this, however, had worked its way out by the following day, and was not reinserted, as the place left for it gaped sufficiently widely to allow of the escape of the small amount of serous discharge which took place afterwards. During the operation strict antiseptic precautions were observed.

The sequel of the case is shortly told. On removing the bone the pulse rose immediately from 72 to 84. On recovering from the anaesthetic the patient was perfectly conscious and he has remained so ever since. The temperature reached 100.2° on the following day, and for several days afterwards remained about 99°. On August 11th—i.e., twelve days after the operation, it went up to 101° for some unexplained reason, but next day it was 99°, and after that normal. The wound seemed at first to have healed by first intention, with the exception of a few granulations near the centre, which required occasional touching with nitrate of silver, but about ten days after the operation a few drops of bloody serum accumulated in the deeper parts on two occasions. No pus was seen throughout. The patient vomited a good deal the day after the operation, and his bowels were sluggish. He was kept on a rigid milk diet, and occasional purgatives or enemata were administered. The only symptom he ever complained of was a general dull headache occasionally. A boracic dressing was substituted for the gauze when the wound became superficial, and this was continued until it had healed. He left the hospital on August 27th, and after spending a month at Eastbourne returned to his employment.

I saw him again on Oct. 6th; he was then perfectly well; he found his memory and mental powers unimpaired, and was doing his usual work, that of a clerk, without difficulty. The scar is firm, and I think some bone is being thrown out, as the sense of resistance beneath it is very great. The case was a particularly favourable one on account of the shortness of the interval between the injury and the operation, and from the absence of complication, but I feel sure that the strict observance of antiseptic precautions removes the most dangerous element from this usually deadly operation. It will be found useful in cases of this kind to supplement the shaving of the head by the application of a solution of carbolic acid in glycerine to the surrounding hairs, which are thus rendered an antiseptic dressing in themselves. This may be reapplied whenever the dressings are changed.

CASE 2.—H. L—, aged forty-one, on May 14th, 1879, was leaning against the door of a loft which happened to be unfastened. It gave way, and he fell on his head into the yard below (which was paved with cobble-stones)—a distance of about fourteen feet. He was stunned at the time, but rapidly recovered; and when he came to the hospital at 12 o'clock he showed no symptoms of a serious injury, and was admitted chiefly because of the nature of the accident. After 1 P.M. he was noticed by the nurse to be sleepy, and it does not appear that he ever actually spoke to her after

that time. At 2 P.M., and several times afterwards, he vomited; and it was observed that he turned over always to the right side, and almost fell out of bed. He slept a good deal. When he was roused he opened one eye—the nurse thinks the left, but cannot be sure; he seemed to understand when spoken to, and nodded in reply, but never actually conversed. If some beef-tea were offered him, he always looked into the cup and tried to take it, but instead of doing so he pushed it away apparently involuntarily; at one time he almost bit a piece out of the cup, and when it was put to his lips his attempts at swallowing only resulted in the fluid escaping at the sides of the mouth. About 6 P.M. the nurse set him up for the purpose of giving him some beef-tea, and spoke rather sharply to him, thinking he was shamming. He did not succeed in taking the food, and in a few minutes it was observed that his breathing had become stertorous; and when, a short time afterwards, he was seen by the house-surgeon he was found to be quite insensible, in an apparently deepening coma, with a pulse of 54; his left pupil being widely dilated, while the right was firmly contracted. There was apparently no paralysis on either side of face or body.

I saw him at 8.15 P.M., and found him in the condition described. The stertor was loud, and evidently caused by the dropping back of the tongue; in fact, on one occasion the breathing stopped completely, and was only restored on pulling forwards the tongue; a piece of bandage placed under the chin, and fastened to the head of the bed, relieved this difficulty in a great measure. Not only was there no paralysis of the limbs, but a pseudo-voluntary effort was made when the hand was grasped. It was thought at one time that the left side of the face was weaker than the right, but this weakness, if it existed at all, was almost imperceptible. The left temporal region—i.e., that away from the injury—had a doughy feel, as if blood were extravasated amongst the tissues, but there was no fulness of the orbit or of the veins of the conjunctiva or the fundus oculi.

It may be thought that these symptoms were enough to justify the application of the trephine over the middle meningeal artery on the left side—i.e., the side opposite the injury; but it must be borne in mind that the onset of the symptoms, having only been observed by the nurse, was very imperfectly reported, that the only unilateral symptoms consisted in the dilatation of the left pupil and the fulness of the left temporal region, and, lastly, that the patient appeared to retain a sort of voluntary power over his limbs.

Under the circumstances, it was decided to wait a short time, and when I again saw him at 11 P.M. the slight alteration that had occurred in the symptoms seemed rather to be in the way of improvement, the pulse being now 120 and compressible, though somewhat irregular, the left pupil having considerably diminished in size, and the movements of the limbs showing apparently a somewhat more voluntary character. I did not therefore feel justified in performing the operation at the time, and he was left till next morning. During the night the condition scarcely altered; the bowels did not act, the urine was passed freely in the bed, and contained a trace of sugar. There were now coarse mucous râles in the chest; and the temperature was 102°. In the middle of the day the only alteration in the symptoms consisted in the fact that the breathing was gradually becoming more obstructed, and late in the afternoon this difficulty rapidly increased, so that the patient died about 6 o'clock. Throughout the day the vomiting continued at intervals.

The post-mortem examination showed that a fracture of the skull extended from the seat of injury into the middle fossa of the opposite side. The hæmorrhage from this had caused the fulness in the left temporal region. The anterior branch of the middle meningeal artery was ruptured (as was found by injecting water through the external carotid artery) just at the point at which the trephine may be most satisfactorily applied in these cases—viz., two inches above the zygoma, and two behind the external angular process of the frontal bone. From the rupture an extensive hæmorrhage had occurred, a large clot, five ounces in weight, having separated the dura mater from the skull, and greatly indented the brain. The only other lesion discovered consisted of two very superficial spots of bruising on the left temporo-sphenoidal lobe.

Here, then, was a case in which trephining would in all probability have saved the patient. It seems worthy of being placed on record, because the symptoms which were so obscure as to lead us to suspect some more grave injury appear to have depended altogether on the pressure resulting

from the hæmorrhage. It is also of great importance to notice that almost no unilateral symptoms were present, a fact which need hardly surprise us when we remember that the pressure must be equally distributed over the whole of the interior of the cranium. It has been pointed out that a widely-dilated pupil is often found on the same side as the clot in similar cases, and this symptom appears to be one well worthy of notice, though it must be confessed that our knowledge of the meaning of the different conditions of the pupil after injuries to the brain is at present very imperfect.

I cannot help thinking that if, as was stated above, the introduction of antiseptic surgery has rendered trephining a far less formidable operation than it used to be, we ought to become less shy of resorting to it. If a distinct interval of consciousness have occurred after the accident, and symptoms so severe as those occurring in the present case supervene, and if there be anything at all to guide us to the side on which the hæmorrhage have taken place, I do not think we are justified in denying the patient the chance which the performance of the operation affords.

Henrietta-street, Cavendish-square, W.

AN ADDRESS PRELIMINARY TO THE DISCUSSION ON RICKETS,

*Delivered before the Pathological Society of London,
Nov. 16th, 1880.*

By C. HILTON FAGGE, M.D., F.R.C.P.,
SENIOR ASSISTANT-PHYSICIAN, GUY'S HOSPITAL.

IT is unpleasant on such an occasion to have to begin with anything like an apology; but unless I explain how I come to be here to-night, you, when you have heard me, will assuredly think that I have done very little justice to my task. On being asked by your Council to open a discussion on Rickets I wrote, as I thought, to decline. I said that I had no new observations to offer you; for although I have always felt a general interest in the subject, I have kept no notes of the cases which I have seen. But your Secretary told me that what was needed was not so much a series of new facts, as a general statement of the questions in regard to the disease which seemed most to require elucidation and discussion, and this I thought I could furnish to you. Other members of the Society, he assured me, had valuable observations on particular points to bring forward; and in offering to you the following remarks, I would disclaim for them any higher position than that of being simply introductory.

There are, I think, good reasons why the subject of rickets should now be taken up by this Society. One is, that in spite of the labours of Sir W. Jenner, and of many others, there is still too great a tendency to attribute to local causes the deformities caused by it, and to overlook the fact that these deformities belong to a general disease. Only a few weeks ago I heard a very eminent physician, in examining the body of a child who had died of bronchopneumonia, speak of the pigeon-breast as if it were merely a result of the pulmonary affection. In that case there were at the wrists and ankles no obvious signs of a rachitic change. But a section through the lower end of the tibia at once showed an abnormal state of the epiphysal line. Is it certain that a pigeon-breast is ever seen in a child whose bones are absolutely healthy? I should like to put this question to the Society, and to follow it with another—Does a rachitic thorax ever acquire the characteristic grooves on each side near the ends of the rib-cartilages without the intervention of some degree of bronchial catarrh? A very slight cough, lasting only a few days, may undoubtedly flatten the sides of the chest in a rachitic infant. But can this result be effected by the mere elasticity of healthy lungs?

The settlement of these questions, and of many others, is greatly retarded by the circumstance that during life it is impossible to determine absolutely the fact that rickets is not present in a slight degree. Even in a child not very fat I have more than once failed to detect any "beading" of the rib carti-

lages through the skin, notwithstanding that at the autopsy they were found to be diseased. And I may notice that the enlargement is often much more marked on the pleural side than towards the surface. On the other hand, there is naturally a slight elevation where the cartilages and the bones meet; and in thin children I have seen this mistaken for "beading," when in reality not the slightest rachitic change was present.

This difficulty as to the clinical recognition of rickets in certain cases is, I think, of great importance in regard to what will probably be the chief subject discussed here this evening—the relation, namely, between the disease and the recently discovered osseous lesions of inherited syphilis. M. Parrot, indeed, ignores rickets altogether. For him a rachitic change in a bone is merely a modification of the syphilitic affection, occurring only in children over six months of age, and attended with an enlargement of the extremities of the bone, and with the formation of a pearly-white osteophyte in its interior and on its surface. He would seem to be almost unacquainted with those histological characters which enable rachitic lesions of bones to be traced from their very commencement. My friends, Dr. Barlow and Dr. Lees, of course, take up a very different position from this. But it has seemed to me that even they, in their observations, have been too ready to assume the absence of rickets when they found no obvious beading of ribs and no marked swelling of wrists or ankles. They do not appear to have been fully alive to the importance of slicing the bones at an autopsy, and of examining their epiphysal lines, both with the naked eye and microscopically. Until this procedure shall have been systematically carried out in a sufficient number of cases, I think that it will still remain doubtful whether cranio-tabes is really related to syphilis rather than to rickets.

There is, however, another and a somewhat different question—namely, whether syphilis may not be one of the causes of rickets. At first, when one is taught that inherited syphilis produces certain definite osseous lesions, one is naturally disposed to think that what has to be done is to draw a hard and fast line of distinction between these lesions and those due to rickets. But what we know of syphilis in adults surely points to a different conclusion. We know that besides producing an immense variety of affections peculiar to itself, it also acts as one of the two causes of the lardaceous change in the viscera, and many suppose it to be also a frequent cause of atheroma of arteries, and perhaps of phthisis.

The characteristic changes of rickets are far more obvious in fresh bones than in those which have been kept in spirit; but I have brought with me a few specimens which have been collected during the last few months, and which show the irregularity of the epiphysal line, the enormous increase in the breadth of the semi-transparent bluish zone of proliferating cartilage, &c.

I have already remarked that rickets is a general disease. The points which show that it is not confined to the osseous system are indeed such as singly might appear trivial, but taken together they possess considerable significance. I am not now referring to the visceral lesions described by Sir Wm. Jenner, and afterwards by Dr. Dickinson, as affecting spleen and liver and lymphatic glands. I have failed to find these lesions in the great majority of rachitic children whose bodies I have examined, whereas I have found a large fleshy spleen in many children who have been free from rickets. And I am much disposed to agree with Dr. Gee, who, after stating that the appearance of the spleen in rickets generally differs in no respect from that which is seen after ague, or in inherited syphilis, adds that in his opinion the affection is really a result "not of the rickets, but of the general state of health which caused the rickets." This, however, is a matter on which valuable experience will no doubt be forthcoming in the course of the present discussion.

Nor can I attach much importance to the so-called "prodromata" of rickets—sickness, diarrhoea, tumefaction of the abdomen, languor, drowsiness, &c. It seems to me that all of them are really either independent effects of the improper dieting and other conditions which give rise to rickets, or else themselves accessory causes of the disease. And it is certain that when one is called to a case of croup or of broncho-pneumonia one often has to deal with an advanced stage of rickets, although the child's mother may have thought it perfectly well up to the time when the acute illness began.

But there are three well-known symptoms of rickets which appear to have no direct connexion with the osseous changes. One is a restlessness at night, which impels the child to throw off its bedclothes, even in cold weather. Another is the tendency for profuse perspiration to break out over the head, neck, and chest, especially during sleep. The third is the sensitiveness of all parts of the body to even gentle pressure. Dr. Gee has shown that this tenderness is by no means confined to the bones, and that the muscles of the loins or of the abdomen are sometimes no less painful when pressed upon, however cautiously.

There is one point with regard to the urine, on which I should be glad to elicit further information. Some months ago I was asked by Dr. Paddon of Putney, to see with him a rachitic boy, whose most obvious symptom was that he passed large quantities of uric-acid crystals. Such a circumstance is surely not common in a child. Since then I have met with another case in which I was told that the urine was extremely irritating and caused scalding pain during micturition. Can this have any bearing upon the supposed presence of lactic acid in the urine? which is certainly one of the points that needs further confirmation.

As to the state of the brain in rickets there are some discrepancies of opinion among different writers. The skull is obviously large, out of all proportion to the narrow face and stunted body. But Ritter von Rittershain showed by accurate comparative measurements that as a rule it is not bigger in rachitic children than in healthy children of the same ages. If so, a very improbable notion suggested by Trouseau falls to the ground—namely, that the softness of the cranium allows of the more easy development of the nervous centres, and that rachitic children consequently possess intellectual faculties in advance of their years. Surely it would be more reasonable to attribute the precocity of such children rather to their being thrown so much into the company of adults, and to the contemplative habits induced by an unfitness for rough play and games. And Dr. Gee speaks of the brain as being dwarfed like all other structures, and describes an effusion of fluid within the cranial cavity to fill up a vacant space there. I should like to ask the Society whether it is certain that hydrocephalus is really a frequent complication of rickets, as all writers seem to say. It is at any rate certain that the skull is sometimes greatly increased in size, without there being any fluid in its interior. I well remember, although I have unfortunately no notes of, a case which I saw in the Evelina Hospital, and which was taken without question for one of very advanced hydrocephalus, until at the autopsy the brain was found to fill the cranial cavity completely. When a grown-up person has a rounded projecting forehead, as was the case with the novelist Thackeray, is the popular opinion correct that an hydrocephalus existed in infancy and has been recovered from? Might there not have been simply a rachitic state of the bones of the skull?

A curious complication of rickets, of which I have seen an example, is a chronic cerebritis. A child, eighteen months old, who had had frequent fits since the age of four months, was admitted into Guy's Hospital in a state of insensibility. It lay on its left side, and whenever it was moved into any other position its whole body became rigid, the mouth being affected with clonic spasms. It died in a few days, and the cerebral membranes, which themselves were thin and transparent, were found to be everywhere adherent to the surface of the brain, so that a thin superficial layer of the cortex peeled off with them. The white substance of the hemispheres was markedly indurated, and had a yellowish colour, and the limit between it and the cineritious matter was ill-defined. This was especially the case at the antero-lateral part of the brain on the right side.

But in many cases spasmodic affections occur without any change in the brain being discoverable. Of laryngismus stridulus, I believe that many observers say that it never occurs except in rachitic children. A year or two ago I had to examine the body of an infant, concerning whom all that I could learn was that it had died suddenly. The ribs showed the appearance characteristic of rickets, and this suggested to me that the cause of death was, perhaps, laryngismus, an idea which was afterwards confirmed by the mother's statement that it had suffered from that kind of disorder. I have certainly seen one case of laryngismus in a little girl, whose general bodily configuration, although she had been brought up by hand, seemed at first to negative the idea that she could possibly be rachitic. But afterwards, when this child got an attack of bronchial catarrh,

her ribs became for a time slightly flattened, and I began to think that her case might not really be an exception to the rule. Tetany is another affection that occurs chiefly in those who are the subjects of rickets.

Both the chemistry and the histology of rickets have been carefully studied, but with regard to each of them I think that there are still points open to discussion. The most recent analyses that I have met with are those which Friedleben made, and the results of which are recorded in the *Jahrbuch für Kinderkrankheiten* for 1860. He found the percentage of earthy salts to be from 33 to 52, which is considerably higher than that obtained by earlier investigators, though it is of course much below the normal percentage of 63 to 65, yielded by the bones of healthy children. But it seems to me that we cannot too carefully guard ourselves against the supposition that any figures of this kind represent the actual composition of the osseous tissue itself, or even that they prove it to differ from the normal. No one can examine the microscopical specimens which I have placed on the table in front of you without seeing that in the bones from which they were taken, if dried and submitted to analysis, there would have been a large proportion of various other structures besides the osseous. Even within the bony trabeculae themselves there are often to be seen very numerous and large islets of residual cartilage-matrix. Why the point is of importance is that, if there were in rickets a real alteration in the chemical constitution of the bones, affecting every particle of their substance, we could hardly doubt that the disease must exist at a very early period, if not from the first setting-in of the process of ossification within the foetus. It does begin earlier than used to be supposed, being not unfrequent in children less than six months old. But whether it is ever present at birth seems to be very uncertain. Cases of foetal rickets have been described by several observers; but all that is as yet known with regard to their histology leads to the conclusion that the lesion is altogether different from that with which we are now concerned.

The curvatures which arise in the shafts of the long bones in rickets show, of course, that these bones are throughout soft and yielding. But it does not necessarily follow that the whole of their substance must be altered in composition. Their diminished resistance may fairly be ascribed to the preponderance of a light and spongy texture, not only in the parts formed since the commencement of the disease, but also in older parts, where it may well result from an over-activity of the absorptive processes which are always at work in their interior.

For there is in rickets one essential and characteristic histological change, which certainly is not diffused through the entire mass of the bones, but affects only their growing surfaces, when they join cartilages, or lie beneath periosteum. Indeed, it would be strictly accurate to say that rickets is not a disease of the osseous tissue at all, but of the soft tissues. Even the so-called "beading of the ribs" is really an enlargement of the costal ends of their cartilages rather than of the ribs themselves. I shall not attempt to describe to you the details of the remarkable morbid process which is observed, and of which I have a series of beautiful specimens, prepared for me by the kindness of my colleagues Mr. Symonds and Dr. Carrington. It is well known that the cartilage cells of the intermediate zone, instead of forming short vertical columns, which should be arranged with much regularity side by side, multiply, so that they become converted into rounded masses of enormous size, some of which bulge towards the cartilage, while others dip and extend far into the bone. The cells themselves have an abnormal appearance, which is aptly indicated by the epithet "dropsical" applied to them in a recent paper by Klebs. Rindfleisch defines rickets as depending upon an acceleration of the changes which usher in and prepare the way for the formation of bone, without the actual ossification keeping pace with them; but, in regard to this definition, I doubt whether the amount of proliferation which must normally take place has been sufficiently appreciated. It seems clear that for a long bone to increase in length, so much as it does from childhood onwards, there must be a far more abundant multiplication of the cells at each epiphysal line than would be indicated by the short columns which are visible at any one time. It may be, after all, that what takes place in rickets is not so much an excessive as an irregular and perverted process of growth. I must also remark that the formation of the so-called "cartilage bone," the occurrence of "provisional calcification" of cartilage-

cells, has appeared to me a much less prominent feature of rickets during its active stage than I should have expected from the accounts given by writers on morbid histology.

With regard to the origin of rickets, it is perhaps worth while to allude briefly to a recent revival of the old "lactic-acid" theory. Wegner of Berlin showed in 1871 that if, while administering minute doses of phosphorus to young animals, he withheld lime-salts from their food, there arose an affection of the bones exactly like rickets. He supposed that the phosphorus acted as a stimulant to the ossifying tissue. Heitzmann has since stated that lactic acid is capable of acting in a similar way. The hypothesis, therefore, as it has been promulgated by Senator, is that the disease is the result of an irritant action upon the growing bones of that acid (which is thought to be formed in the alimentary canal in excess from milk or other articles of food), there being at the same time a deficiency of phosphate of lime, consequent either on its being ingested in too small quantity, or on its being carried away through the bowels by diarrhoea. The weak point in this speculation is of course the circumstance that no excessive formation of lactic acid has been proved to occur.

As to the causes of rickets, again, there are a great variety of opinions; but I think not very many accurately determined facts. In this country the prevailing doctrine is that improper feeding of infants is the chief, if not the sole cause. But among Germans it is interesting to notice that Vogel, in the last edition of his work, says not a word about the possible influence of diet, and insists on defective ventilation—the want of fresh air—as the most important factor in the etiology of the disease. And of ourselves there are some who think that it is especially apt to be caused by farinaceous food, such as potatoes, when given too early; others attribute it mainly to a premature deprival of the natural food of a baby—its mother's milk.

Most English observers doubt whether rickets is capable of direct hereditary transmission. If it occurs in the children of a rachitic parent, they think that in each generation the hygienic influences have been adverse. But Vogel says he knows many families in which, the parents showing distinct signs of having been formerly affected, the children have all become rachitic in turn, in spite of every precaution. Sir Wm. Jenner has expressed a doubt whether impairment of a father's health has any tendency to induce rickets in his offspring; whereas Ritter von Rittershain thought that he traced it to the presence of tuberculous disease in the father more often than in the mother. But, among the poor, how are we to say what links there may have been between the supposed cause and the effect? The illness of a labouring man may deprive his wife of nourishment, throw heavy work upon her, and in many different ways render her likely to bear weakly infants; it may prevent the children from receiving proper food, may interfere with their being taken out into the open air, may confine them in small and cramped rooms, and may limit their supply of warm clothes.

A point on which Sir Wm. Jenner has laid great stress is that the first child of a family, or even the first two or three children, are often found free from rickets, when later ones are affected with the disease; and, again, that when a woman has once had a rachitic infant, those that follow are almost sure to suffer. But this may be due either to the progressive enfeeblement of the mother's health by repeated childbearing, or (among the poor) to the overcrowding and deficient food and clothing which are implied by a large family; while children of even the better classes are often kept far too much in-doors, when there is only one nursemaid for several of them.

The only conclusion seems to me to be, that the conditions of life in large towns are too complex, and too little capable of being isolated from one another, to allow of a separate study of their effects. Hitherto it has not been possible to trace rickets to any one special exciting cause; but, on the other hand, we are surely not justified in saying that no such cause exists.

It is clear that if rickets can be set up by feeding a child improperly, or by any other unfavourable conditions of life, it is not, in a strict sense, a diathesis. Thus one can no longer, with Sir William Jenner, set forth a contrast between it and other diathetic conditions. But its relation towards tuberculosis is a question of great interest and well deserves further elucidation. Dr. Eustace Smith, while doubting the diathetic character of rickets, remarks that it "never occurs in children in whom the tubercular disposition is well marked." At first this appears a striking state-

ment, but it loses all its significance when we remember what are supposed to be the signs of a tubercular disposition; since for a rachitic child to present them would be almost a contradiction in terms. And it would seem that it must be impossible to uphold Sir Wm. Jenner's distinctions between scrofulosis and tuberculosis, now that so many pathologists find grounds for maintaining that cheesy glands and chronic joint- and bone-diseases commonly form the starting-point of an infective tuberculosis. For my own part, I must confess that I doubt whether any special configuration of body carries with it a *positive* tuberculous tendency. It seems to me that the only character presented in common by the majority of phthisical and scrofulous individuals is a *negative* one—namely, the absence of a perfectly robust and vigorous frame. In whatever direction the body deviates from the highest standard of health, except as the result of the actual presence of some other disease, I believe that the liability to tuberculosis is increased. If so, however, one would certainly expect that rachitic children should often be also tuberculous. Sir Wm. Jenner, indeed, himself states that rickets does not by any means exclude tubercle, and I have lately met with a case in which both diseases were present in the same infant. As regards family tendencies to tubercle in those who are the subjects of rickets, Ritter von Rittersheim proved that a large proportion of the fathers of rachitic children were tuberculous, whereas Sir Wm. Jenner alludes to a table made for him by Dr. Edwards, which appeared to show that the offspring of phthisical parents were actually less likely than those of non-phthisical parents to become affected with rickets.

In conclusion, I would urge as slight additional incentives to the study of rickets by English physicians, its great frequency among us, and the fact that one of the traditional names for it is *morbus Anglicus*. The suggestion was even once made that it originally spread from this country to the Continent; but the name in question probably had its origin in the title of a treatise published by Whistler at Leyden in 1684, "*De Morbo Puerili Anglorum*." The term rachitis was first proposed by Dr. Glisson, of Cambridge, two years later. One can hardly doubt that he really adopted it on account of its similarity in sound to the word rickets, which was a popular name for the disease in the west of England, where it seems to have been first recognised. But Glisson, in his work on the subject, offers to his readers the choice of a Greek root, *ῥαχίς*, on the ground that the spine is one of the first parts to be attacked! It has probably seldom happened that the fabricator of a scientific appellation has thus himself made apparent the weakness and inaccuracy of its etymology. But I have little doubt that there are many other terms which, having been made, instead of growing spontaneously, have no better origin; and, if so, what can be more futile than to spend time and labour in searching out for such bastards a legitimate pedigree, to which they really have no claim?

THE ADMINISTRATION OF ANÆSTHETICS.

By ROBERT SAUNDBY, M.D. EDIN., M.R.C.P.,
ASSISTANT-PHYSICIAN, LATE PATHOLOGIST AND CHLOROFORMIST, TO
THE GENERAL HOSPITAL, BIRMINGHAM.

It may be assumed that the anæsthetic agents usually employed in practice are ether and chloroform. Moreover, it may be affirmed that they are so safe and satisfactory that while we all shall welcome any better, it is not wise to abandon these well-tried means for every new compound possessing anæsthetic properties, with nothing else to recommend it but its novelty.

But these agents are neither satisfactory nor safe unless properly administered with due discrimination of the cases suitable to each. The reports of deaths from both chloroform and ether which appear nearly every week point to the urgent need for those who have larger practical experience than ordinary to formulate their opinions. Even at the risk of being considered dogmatic, I shall try to state accurately what are the methods I use, the precautions I have found necessary, and the errors I have learnt to avoid in the administration of anæsthetics; and I hope by clearly enun-

ciating my own views to raise certain questions in a definite manner, which shall be capable of being affirmed or denied, but at any rate must be answered.

The agent to be preferred.—As a general rule, I prefer ether, because I believe it to be safer, the public believes it to be safer, it is a perfectly satisfactory anæsthetic, and its after-effects are less depressing than those of chloroform. The kind of ether I use is Macfarlane's methylated ether, as made for Dr. Keith, because it is cheaper, and in every way as good as the more expensive kinds. The apparatus I employ is a towel folded lengthwise, with three or four thicknesses of paper between the folds, made into a cone by twisting it on one hand, and fixing it with a few safety pins.

Preliminary arrangements.—No solid food should have been taken for at least three hours before the time fixed for the administration. I can recommend the plan proposed and practised by my friend Mr. Priestley Smith of administering a dose of chloral hydrate an hour before. Do not give brandy or any other stimulant just before administering ether; it is unnecessary, will probably be vomited, and introduces another factor into the conditions which we should try to keep as simple as possible. Examine the chest and make inquiries as to cough in all cases. Inflammation of the lungs or air-passages forbids the use of ether. The vapour of ether irritates healthy lungs, often to an excessive degree, and sometimes causes a slight bronchitis for a day or two, while occasionally it gives rise to fatal oedema of the lungs, even where no previous disease existed in these organs. It is therefore plain that all inflammatory conditions of the lungs are likely to be made worse by ether. Chloroform is to be preferred in all such cases. Cardiac disease *per se* does not contra-indicate ether, as the drug aids a weak heart. In aortic incompetence with badly filled arteries the circulation becomes better during the administration of ether. In mitral disease the case is somewhat different. It must be remembered that ether frequently causes spasmodic dyspnoea, which ordinarily need cause no alarm, and calls for nothing but temporary suspension of the administration, but during which there is great venous turgescence, and the right side of the heart is necessarily overloaded with blood. So that wherever I have reason to believe that the right side of the heart is weak and dilated I should prefer chloroform to ether. The same would hold good of dilatation of the right ventricle apart from mitral disease.

Fractures, herniæ, and other conditions in which complete muscular relaxation is required are cases in which, *ceteris paribus*, I should use chloroform.

Operations about the face can sometimes be performed only with difficulty, or not at all, while ether is being administered; in these chloroform must be employed.

Young children take chloroform with such ease and safety that it is to be preferred for them.

Method of administration.—The orifice of the cone should be large enough to cover the lower two-thirds of the patient's face, and take in the chin and lower jaw. It is always preferable to have the patient lying down with his shoulders a little raised, and his head not much higher than his shoulders; the pillow should be firm and flat; unfasten anything that is round the patient's neck; ask him to turn his head with the *right* cheek on the pillow, to shut his eyes and mouth, to breathe through his nose; tell him to try to go to sleep, and assure him that the ether will be given him cautiously. Pour about an ounce of ether into the cone, and approach it slowly towards the patient's face; with a little encouragement he will soon submit to having it brought quite close, for partial anæsthesia is rapidly induced. When once it is close to his face it should not be removed for some minutes, in spite of any struggles or protests. Fortunately, patients rarely recollect what occurs at that time if the cone has been approached gradually. The ether should be given liberally, as atmospheric air is being excluded, and the patient is respiring nothing but ether vapour. Stertorous breathing is a sign that the patient is "over," and that the operation may begin. If there is much lividity, stop giving ether for a short time, and the natural colour will soon return. The ether must be given almost continuously throughout the operation. Stertorous breathing is not a warning of danger. On the contrary, I like to hear this noisy breathing, as I feel sure my patient is going on all right.

Cautions.—It is absolutely necessary that one person should do nothing else but administer the anæsthetic. He should never leave his post to assist or perform other duties. His business is to give the anæsthetic and to watch the

breathing. He should let his own breath, as it were, hang on the breathing of his patient, so that he cannot breathe himself till his patient breathes. In this way he will be able to detect the slightest irregularity. With ether there is often some spasm, and respiration stops for a time, but a tap on the chest or rotating the head starts it again, as a rule. If inspiration seems difficult, remove any mucus from the fauces with the finger, draw out the tongue with a pair of artery forceps and pull it well forward, so as to open the glottis. If this does not succeed, artificial respiration must be resorted to while the tongue is still drawn forward, but it is satisfactory to say that I have never yet needed to have recourse to it.

The colour of the skin of the ears is a good index to the state of the circulation. If these are livid, the administration should be stopped temporarily.

After the operation.—It is prudent not to leave the patient, or at least except in the care of a properly qualified medical attendant, until he has shown signs of returning consciousness. This may be hastened by sponging his face with cold water, or slapping it gently with a wet towel, not so roughly as to cause marks. Sometimes holding the nose provokes a long inspiration through the mouth, followed by the sudden return of consciousness. This manœuvre is of no use when ruder measures fail, but it may precede them, and is often successful.

Where chloroform, for any of the reasons given above, is to be preferred, I administer it on a towel folded square. The preliminary arrangements and precautions are much the same as in the case of ether; but the patient requires, if possible, more careful watching. The reflex sensibility of the eye must be tested frequently; when it is abolished the operation may commence, and the chloroform should be administered with caution. Stertorous breathing is a warning to suspend the administration. Should respiration stop, the tongue must be drawn out, and artificial respiration commenced at once. The respiration must be watched continuously. The pulse may be disregarded, as it gives no timely warning of approaching danger. *Although chloroform does not require to be administered continuously, it is not less necessary to continue to watch the respiration, even though no chloroform is being given.* Accidents often happen from disregard of this precaution. The chloroform may be safely poured freely on the towel, but this should be cautiously approached to the face, until finally the fingers of both hands press its lower edge against the margin of the jaw, while the surface of the towel forms an angle of forty-five degrees with the face. The experience of the Edinburgh school affords the widest basis for affirming the practical value and safety of this method of administering chloroform.

I have had two deaths from anæsthetics—one from chloroform and one from ether. The former was a case of gummatous disease of the larynx, for which tracheotomy was performed when the patient was nearly moribund from asphyxia. It was in my early days, and at the present time I should decline to administer any anæsthetic in such a case. The other was from acute œdema of the lungs supervening some hours after the administration of the ether, and which I fully reported at the time. Both were hospital cases. In the numerous administrations I have had in private I have never met with a case which has given me any cause for alarm, though many have given me much anxiety. Indeed, I may say I never administer anæsthetics without anxiety; for it appears to me no slight thing to hold a fellow-creature suspended between life and death for an hour or more, during which each respiration is watched for anxiously, and all our attention is strained to notice the first indication of impending danger.

In conclusion, I will recapitulate the points which I desire especially to insist upon:—1. Ether is to be generally preferred as an anæsthetic. 2. Inflammatory affections of the lungs and air-passages absolutely contra-indicate its employment. 3. It should be the sole business of one person to administer the anæsthetic during an operation. 4. The breathing must be watched so long as the patient is under the influence of the anæsthetic, whether it is still being administered or not.

FOOT-AND-MOUTH DISEASE.—After the lapse of nearly two years, foot-and-mouth disease has again made its appearance in Lancashire. It is supposed to have been introduced by some Scotch cattle purchased recently in Scotland. The disease has also broken out at Sheffield.

NITROUS OXIDE AS AN ANÆSTHETIC IN SQUINT OPERATIONS.

By W. A. BRAILEY, M.D.,

CURATOR AND REGISTRAR, ROYAL LONDON OPHTHALMIC HOSPITAL.

As nitrous oxide, though of late occasionally used and favourably spoken of in America by Dr. Mathewson and others, has, I think, not been hitherto tried in this country, the following brief recital may be of interest.

W. S. W.—, aged eighteen, healthy and robust, is the subject of a convergent strabismus of his right eye of four millimetres. It having been decided to use nitrous oxide, he was put fully under its influence by Mr. Spencer in eighty seconds, and was retained so for two minutes and a half, during which time a tenotomy of the right internal rectus was performed. During the last thirty seconds of this time the inhaler was withdrawn. He recovered instantly after the operation, without any unpleasant symptoms, though he declares that he felt some pain during its terminal stages.

A tenotomy being now seen to be necessary on the other eye, the gas was again administered. This time, however, he did not come under its full influence till the expiration of four minutes. His conjunctivæ became extremely tumid and congested. The tenotomy occupied ten minutes, owing partly to the awkward position of the operator on the left hand of the patient, on account of the inhaler, and partly to a tendency to the return of sensibility on the least shifting of the inhaler.

Recovery from the anæsthesia was almost immediate, and no unpleasant after-effects of any sort were experienced. The inhaler employed was that of Clover.

Nitrous oxide is preferable to both ether and chloroform, in being more safe, more rapid in its effects, and much more agreeable to take. It leaves no unpleasant after-effects at all comparable with the others. In this respect it as much excels ether as in the question of safety it is superior to chloroform. The want of full relaxation of the muscles is no impediment to its use in strabismus. Its average cost is rather more than that of the others; but this is of no moment if the advantages above claimed for it are established. Doubtless a face-piece offering less impediment to the operator could easily be arranged.

Though squints may be efficiently operated on without the use of an anæsthetic, yet this procedure undoubtedly involves considerable pain to the patient.

A METHOD OF MORE EFFECTUALLY SECURING SAYRE'S JACKET AFTER IT HAS BEEN CUT.

By NICHOLAS GRATTAN,

SURGEON TO THE COUNTY AND CITY OF CORK HOSPITAL FOR WOMEN AND CHILDREN.

IN treating spinal disease I have lately adopted a plan for fastening Sayre's plaster jackets after they have been cut, which I consider better than the old method of having them bound with leather and laced. The jacket should be sawn and cut through a quarter of an inch at each side of the median line, and the middle strip of half an inch wide removed. Two pieces of strong telegraph wire must be procured, the entire length of the jacket, the layers of bandage of which the jacket is composed, are, at each side, to be equally divided, and the wires placed between them; then the strips of bandage and the lining-vest must be firmly top-sewn together over the wire, in the same manner as the steels are secured in the front of a lady's stays. Just inside the wire, through the jacket and vest, holes are to be bored with a small bradawl down each side of the jacket, at intervals of an inch. The jacket having been put on, and laced very loosely with whipcord, the patient must be suspended, the jacket brought into proper position, and the cord drawn tightly and fastened.

Plaster jackets laced in this manner will be found even stronger than before they were cut, and they can be removed at intervals, for the purpose of cleansing the patient, and when reapplied will be found as effective as ever.

My reason for removing a strip half an inch wide, is that

I have almost always found on cutting a jacket that it has become too large, either through the patient having diminished in size or the jacket having stretched.

This plan renders the surgeon quite independent of the workman, as with a knife, a bradawl, needle and thread, and a piece of stout wire, any jacket can be cut up and reapplied by the surgeon himself in a short time.

UNIVERSITY COLLEGE HOSPITAL.

CASE OF EXTENSIVE EPITHELIOMA OF THE LOWER JAW
AND FLOOR OF THE MOUTH; REMOVAL; SATISFACTORY
STATE TWO YEARS LATER.

(Under the care of Mr. CHRISTOPHER HEATH.)

THE following case is a very encouraging one to those surgeons who do not hesitate to operate on cases of extensive epithelioma, in which all the disease can be removed and no glandular complication exists. The very serious nature of the case if left untreated when the disease involves the mouth is too obvious to all, but it unfortunately happens that the early stages of epithelioma of the gum are either overlooked or are maltreated by inefficient caustics. In a recent case Mr. Heath succeeded in removing the alveolus and a considerable amount of disease from beneath the tongue without any external incision, employing Paquelin's cautery for the sublingual portion.

The following notes were taken by Mr. Easmon.

John S—, aged sixty-eight, plumber, was admitted on the 9th of January, 1879, with epithelioma of the left lower jaw and continuous mucous surfaces of the floor of the mouth and cheek. In the early part of October, 1878, the patient noticed that his three left lower molar teeth were loose, and they were accordingly extracted. About the beginning of November he noticed, for the first time, a small sore on the left side of the floor of the mouth, corresponding in position to the teeth removed. This gradually and almost painlessly increased in size. The patient began to suffer likewise from nausea, especially in the morning. A medical man who was consulted ordered red wash for the mouth. Three weeks later he began to apply caustics, which he did six or eight times altogether. About a fortnight before admission the sore began to bleed and continued to do so. There was no history or evidence of syphilis, and patient alleged he had always been healthy. He was a smoker. He did not know the cause of death of either of his parents, both of whom, he said, had lived to old age. His brothers all died at a comparatively early age, ascribed, by the patient, to their unhealthy occupation as masons. He was unable to give an account of the nature of their last illness.

On admission he was a corpulent but very anæmic man, looking younger than his real age, and had general tremors. He was losing flesh, because the condition of his mouth allowed him to take but little food. The bowels were regular, and the general health fair. He suffered from sleeplessness, and pains about the affected side of face of a radiating and lancinating kind.

On opening the mouth, an ulcerating mass of new growth was observed involving the left half of the floor of the mouth, and adjoining alveolar process of lower jaw, the surface of which was composed of large vascular granulations, ragged and covered at the posterior part with small sloughs. To the feel it was soft and extremely tender, extending *backwards* as far as the ascending ramus of the jaw, *inwards* to the middle line, and in front beyond this to the right as far as the right canine tooth, which was very tender when pressed upon, although on the outer side—i.e., between the gums and lips—it was not evident beyond the

mid-line. The structures at the floor of the mouth were involved to a considerable depth, but the tongue was free. *Externally* it involved the alveolar process of the lower jaw on the left side, and extended to the junction of its gingival mucosa with that of the cheek. The teeth of both upper and lower jaw were discoloured; the left lower molars and the right lower molars and bicuspidis were absent.

No enlargement of lymphatic glands could be felt in the neck, nor was there any induration or tenderness beneath the jaw. There was a sanious fetid discharge from the growth, and slight stomatitis. The tongue was furred, especially at the back, and red at edges.

Urine: sp. gr. 1018; neutral; high coloured; no albumen or sugar.

The heart and lungs were healthy. Neither spleen nor liver was enlarged.

On Jan. 22nd, at 3 P.M., the patient was put under the influence of chloroform, and Mr. Heath extracted the right lateral incisor tooth, and then cut through the lip and soft structures down to the lower border of the jaw. The jaw was then sawn through at the point where the tooth had been extracted. A string was now passed through the tongue by which that organ may be drawn out if necessary in case of impediment to breathing (which did occur once or twice during the operation). Mr. Heath next divided the structures beneath the lower border of the jaw, beginning at the lower end of his first incision, and ending just in front of angle of jaw, the facial artery being secured by hare-lip pin ligature. Turning back the cheek flap, the jaw was sawn through about an inch and a half in front of the angle, and the piece of bone included between the two saw-cuts, together with the greater part of the growth attached, removed by dividing the soft parts of floor of mouth attached to it. At this stage much hæmorrhage occurred, chiefly from the lingual artery and its branches, which were all ligatured. The dental foramen in the portion of jaw left behind having been closed with a spigot of wood, the remainder of the growth was dissected off the flap. The parts were then mopped out with a strong solution of chloride of zinc; all suspicious particles removed; the flap was brought down and secured by four or five fine wire sutures, two hare-lip pins and twisted sutures being employed to secure the lip with an additional suture of fine silk at the upper part at the verge of its mucosa. At the posterior part of the wound a small opening was left, through which the end of the ligature applied to the facial artery was allowed to protrude, acting instead of a drainage-tube. The edges of the wound were finally painted over with collodion, and covered with dry lint, and the patient put to bed. The string in the tongue was allowed to remain and kept out of the mouth, in case its use should become necessary.

On examining the growth removed it presented all the naked-eye appearance of an ulcerating epithelioma, involving the alveolar process as far back as the last molar tooth, while forwards it was coextensive with the excision. It spread outwards to the adjacent part of the cheek, but involved only the mucosa, and not the deeper structures. Inwards it reached along the floor of the mouth as far as mid-line. The tongue was not involved. The posterior section of the face showed two questionable-looking spots of probably an extension of the growth.

The patient's pulse became irregular and feeble after the operation, and he appeared somewhat collapsed, but brandy was administered, and he had ice to suck. There was little trouble with the tongue, and he slept well during the night. Next morning the pulse was still feeble, but regular, and the patient seemed to be in good spirits.

On the 24th patient complained of headache. He had slept fairly during the night. The pulse was very weak, 92; temperature 99°; respiration 24. As he had not taken his food well an enema of beef-tea and brandy and eggs (of each one ounce) was administered. The mouth was carefully washed out with a good quantity of warm solution of Condy's fluid lotion. Discharge not very offensive.

On the 25th he had slept fairly well. He complained of pains in the lower lip and up the left side of the face. The pulse was still very weak, 92; temperature 99°. The parts were well syringed out.

On the 27th the patient was looking quite bright. The parts were doing very well. The sawn surfaces of the bone could be seen covered with granulations.

On the 29th the temperature was normal, and the patient had thoroughly recovered from the effects of the operation.

The discharge from the mouth drained through the lower opening, and was only slightly offensive.

From this time the patient made a rapid and steady recovery, and was discharged on February 21st to go to Eastbourne. He returned in March with the mouth quite healed. In November, 1880, the patient visited the hospital in perfect health, having grown stout and strong for his age. The mouth was perfectly sound, the gap in the jaw being filled by firm, dense cicatrix, covered with healthy mucous membrane, and the right side of the jaw being drawn inwards by the action of the muscles, as is usual in cases of division of the mandibles.

GLASGOW ROYAL INFIRMARY.

INTRODUCTION OF A TRACHEAL TUBE THROUGH THE MOUTH FOR THE ADMINISTRATION OF CHLOROFORM DURING AN OPERATION FOR THE REMOVAL OF EPITHELIOMA FROM THE MOUTH AND FAUCES.

(Under the care of Dr. MACEWEN.)

FOR the following notes we are indebted to Mr. McCall, house-surgeon.

J. B—, aged forty-five, was admitted on July 31st, 1880, suffering from epithelioma of the posterior portion of the tongue on the right side, and also of the right pillar of the fauces, extending to the epiglottis. Eleven weeks previous to admission the patient's attention was drawn to the tumour. For several years he had been in the habit of indulging excessively in alcohol. His heart was enlarged and was slow and feeble in action. He had slight chronic bronchitis. His mind was somewhat obtuse.

On August 3rd a tube was inserted through the mouth into the trachea, through which chloroform was administered. The upper portion of the epiglottis was occluded round the tube to prevent the entrance of blood. An incision was made through the right cheek from the angle of the mouth to that of the lower jaw, the latter being sawn through and held aside. The right half of the tongue, with the exception of a quarter of an inch from the tip, was removed, as well as the implicated portion of the fauces. The bleeding was arrested, the angle of the jaw drilled and secured by a couple of wire sutures, the soft parts being brought together, the patient was roused from the chloroform, and the tube was withdrawn from the trachea.

On August 10th the wound was looked at for the first time, and found healed, with the exception of the apertures through which the wires from the jaw protruded. The wires were removed, the one on August 31st, the other on Sept. 5th. A slight swelling remained on the right side of the face.

Remarks.—The insertion of the tube into the trachea was easily effected; it was followed by little spasmodic cough; the inspirations were perfectly carried on through it. The administration of the chloroform through the tube, the extremity of which projected several inches beyond the mouth, was continuous during the whole operation, without in any way interfering with the operator. This is the fourth patient on whom these tubes have been passed through the mouth into the trachea.

ASHBURTON AND BACKFASTLEIGH COTTAGE HOSPITAL.

CHRONIC EFFUSION INTO BURSA PATELLÆ AND BURSA LIGAMENTÆ PATELLÆ; COMMUNICATION BETWEEN THE TWO BURSAE.

(Under the care of Dr. JAMES ADAMS.)

D. T—, aged sixty-nine, a shoemaker, with marked congenital talipes varus in each foot, was admitted on July 17th, 1880, with an unhealthy ulcer, as large as half-a-crown, over right patella, and with the bursa patellæ and bursa ligamentæ patellæ much distended with fluid. The two bursæ communicated, for the fluid could be distinctly pressed from one to the other. The patella could be obscurely felt through the bag of fluid over it. For two years he had had considerable enlargement of the knee, unattended with pain and not interfering with his work. About two months before admission the skin over the patella broke down, and a fortnight before admission there was, he said, a copious discharge of fluid from this spot. Twice during the last two months he had the bursæ tapped and emptied, but the fluid soon returned.

On July 19th a grooved needle was passed into the bursa patellæ through the ulcerated surface, and five or six ounces of straw-coloured fluid pressed out. There was no pus. He was kept in bed, and a bandage applied as tightly as possible over both bursæ. A poultice of linseed-meal and charcoal was applied to the ulcer.

On the 26th the ulcer was healthy, and healing. Lead-lotion was ordered instead of the poultice. There had been a small amount of fluid discharge from the bursæ, sufficient to stain the bandages.

On August 3rd the bandages were taken off. The bursa patellæ was normal, but the bursa ligamentæ patellæ was refilling. Tincture of iodine was applied twice a day to it. Five grains of iodide of potassium and one-sixteenth of a grain of perchloride of mercury were taken thrice daily.

On the 10th the bursa ligamentæ patellæ was getting larger. Cantharides plaster was applied over it instead of tincture of iodine. To continue the medicine.

On the 19th the patellar ulcer was filling up. The internal and local medication had no effect on the refilling bursa. It was therefore punctured with a small lancet, at the lower part, under carbolic spray. Two ounces of dark-coloured fluid were evacuated, and the wound was then strapped firmly with diachylon plaster, and a common splint put on under the knee, with a pad tightly bandaged over the bursa. He was kept in bed a week with splint and pad on, and every other day a probe was passed as far as possible through the lancet puncture into the bursa. He was discharged Aug. 28th with both bursæ empty.

When seen afterwards there had been no return of fluid in either bursa.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Deformity of Leg and Foot.—*Congenital Malformation of Heart.*—*Rickets.*—*Cranio-tabes.*

THE ordinary meeting of this Society was held on Tuesday last, Mr. T. W. Nunn in the chair. There was a very large attendance of members, attracted by the discussion on rickets. In accordance with the desire of the council a short portion of the time was devoted to the consideration of a living specimen and a card specimen. The debate on rickets was opened by Dr. Hilton Fagge, who was followed by Drs. Barlow and Lees. Dr. Crisp spoke to the occurrence of rickets in the lower animals, and then, on the motion of Dr. D. Powell, the discussion was adjourned.

Mr. PEARCE GOULD showed a child three years old, the youngest of a family of seven children, all the others of whom were well formed. The mother of the child, when between two and three months advanced in pregnancy, fell heavily on her face and belly, and received a severe shake. The pregnancy advanced normally, but the child at birth was found to have a deformity of the left leg and foot. The thigh and knee-joint were normal, but the leg was shorter than its fellow; the tibia was sharply curved forwards below, and over the prominence of the crest the skin was grooved. There was nothing to be felt of any part of the fibula. The foot was small and short, and had only the three inner toes, the two outer of which were webbed. The child walked on the inner malleolus of the tibia, and inner side of the foot. The muscles of the leg were all present, and Mr. Gould thought he could feel a thick interosseous membrane running down the outer side of the leg. There was no evidence of the existence of the cuboid and fourth and fifth metatarsal bones. The biceps cruris muscle was small, and could be traced to its attachment to the outer condyle of the tibia. Dr. Meyersohn had collected eleven cases of complete absence of the fibula. In Dr. Förster's work on malformations another case is figured, and Dr. Humphry has stated that he found a specimen of absence of the fibula and cuboid on both sides in the Musée Dupuytren, and the case shown would make a fourteenth case. Instances of absence of a part of the fibula are more frequent.—Mr. ADAMS thought cases of partial absence of fibula were not unfrequent; he had seen several such, in all there was a dimple in the skin, which had been taken as evidence of intra-uterine fracture,

but this was incorrect. He thought in such cases there was really fusion of the two bones; it was well to remember that in the adult there was always three to five inches of shortening.

Dr. PEACOCK showed as a card specimen a Heart removed from a child six years old, in which there was marked stenosis of the pulmonary artery, a large aperture in the ventricular septum, the aorta arising from both ventricles. The foramen ovale was closed. This was the commonest of all the congenital deformities of the heart.

THE DISCUSSION ON RICKETS

was then opened by Dr. HILTON FAGGE, whose address we publish in full in another page.

Dr. LEES communicated the results of an investigation which had been carried on by Dr. Barlow and himself, with a view to determine the true nature and causation of the condition called *cranio-tabes*, which has since the time of Elsässer, its discoverer, been generally accepted as the first sign of rickets. *Cranio-tabes* consists in an abnormal softening of portions of the parietal and occipital bones, causing them to yield to moderate pressure, and impart to a finger pressed upon them a sensation like that derived from stiff parchment or from the surface of a bladder. There is now no doubt that some symptoms occurring in the first year of life, which have been ascribed to rickets, are really due to congenital syphilis, and it seemed a question worthy of examination whether *cranio-tabes* is not really a result of syphilis, and how far it seems to be connected with rickets. It was soon found that the condition was one quite common amongst the children of the poor of less than one year of age. The authors collected 100 cases, and investigated them as carefully as they were able. For the second 50 cases printed forms were used which directed attention—(1) to the maternal history, especially as to previous miscarriages, or stillborn or premature children; (2) to history of syphilitic symptoms in older children; (3) to the history of the child suffering from *cranio-tabes*, including syphilitic symptoms and those usually deemed rickety; (4) to its weight and age, with an account of the way it had been fed; (5) to its present symptoms in detail, especially the state of the skin, mouth, nose, voice, skull, thorax, long bones, and viscera, particularly the liver and spleen. The results of these investigations were submitted to the Society in a tabular form, from which it appeared that in 70 out of the 100 cases the condition of *cranio-tabes* was marked, in 30 it was slight. After weighing the evidence as to syphilis in each case, the authors felt satisfied as to the existence of the taint in 47 cases, and thought that this conclusion could not fairly be challenged in more than six or seven instances. In about 40 more of the cases there were some indications of syphilis, of greater or less value. In 12 cases no evidence of syphilis could be found. It was pointed out that even in these latter syphilis might possibly be the cause at work, for the children of undoubtedly syphilitic parents at times show nothing beyond *cranio-tabes* and *marasmus*. Cases were narrated which seemed to show that sometimes *cranio-tabes* is the only sign of a gradually diminishing syphilitic taint. It was pointed out that marked *cranio-tabes* not unfrequently occurs in well-nourished infants, who have never had a day's illness, and have been brought up exclusively at the breast. A list was given of seven such children, with their age and weight. A list of the weight and age of nine *marasmic* children, who were extremely wasted, and yet had no *cranio-tabes*, was also given. The inference was that *cranio-tabes* is not simply a part of a general *marasmus*. Some comments were made on the cases narrated by Elsässer and on the difference in symptoms accompanying the *cranio-tabes* according to Elsässer, and in the experience of the authors. The conclusion at which they arrived was that syphilis is by far the largest factor in the causation of *cranio-tabes*. To determine whether it is the sole cause it would be necessary to examine a large number of infants in reference to whom the question of syphilis could be absolutely excluded. The authors strongly suspect that when this has been done it will be found that *cranio-tabes* is always a result of syphilis. To determine whether it has any connexion with rickets they tabulated the rickety symptoms (if any) observed in 53 cases of *cranio-tabes*, arranged according to age, from two to nineteen months old. It was found that all the later cases in this table showed some, though at times very slight, evidence of rickets. It would not, however, be safe to infer at once from this fact that *cranio-tabes* is the first sign of rickets without an inquiry into the manner in which the children

had been fed. Of the thirty-five infants in this table of not more than six months old twelve had been brought up exclusively at the breast. Not one of these showed any evidence of rickets whatever. Fourteen had been partly suckled and partly fed by hand; 9 suckled for less than one month or not at all. Nine of the former 14, 6 of the latter 9, showed distinct signs of commencing rickets. Of the 15 children in this table of more than six months of age, 5 were still partly suckled at the time that their *cranio-tabes* was noted. Of these 1 showed very slight signs of rickets, 1 slight signs, and 3 a moderate amount. But of 9 who had been suckled for less than six weeks, 2 showed slight signs, 3 a moderate amount, and 4 a marked degree of rickets. These facts tend, so far as they go, to show that the rickety manifestations bear some definite relation to the diet. The fact, therefore, that all the older cases of *cranio-tabes* showed some signs of rickets does not itself prove the truth of Elsässer's idea, for they were all more or less improperly fed. And a syphilitic child may be expected to be at least as liable to injury from a faulty diet as a child free from this taint. Even if it could be proved that *cranio-tabes* is the first sign of rickets, that would, of course, in no way invalidate the proof that *cranio-tabes* is itself the result of syphilis. The only conclusion would be that syphilitic children are specially apt to become rickety. Whether it is so or not is uncertain; for themselves the authors confessed that if *cranio-tabes* and enlargement of spleen be transferred from the category of rickety symptoms to that of the symptoms of inherited syphilis, they have as yet no proof that syphilis *per se* is a cause of rickets.

Dr. CRISP had found rickets most common in children reared in poor, overcrowded neighbourhoods, but had seen many cases among the well-to-do classes. He thought the cause lay rather in the quality than the quantity of the food. He thought the cause of rickets was better known than that of any other disease, but it was a cause that might produce other diseases, and, in illustration of this, cited the case of a family in which one child died of tubercular meningitis, and another of chronic hydrocephalus, and a third suffered from severe rickets, which caused permanent deformity. Among animals the disease was so widespread that there were no vertebrata in which it might not occur when they were placed under special favouring conditions, but it was not so prevalent as in man. Dr. Harley had shown at the Pathological Society the bones of a rickety horse, Dr. Dick the bones of two Italian greyhounds, also rickety, and he himself had more recently exhibited the rickety bones of several young pheasants which had been kept in a confined space and fed on improper food. London-bred poultry, which are often not well fed and kept in bad air, have a marked deficiency of phosphate of lime in the sternum, which is soft and bent. A young ostrich hatched at the Zoological Society's Garden died at once from the falling in of its soft ribs; and all the lions born in the Gardens had soft bones, and nearly all of them had died before reaching maturity, while lions born in travelling menageries often live. Large dogs are often thus diseased, as are also lambs in cold, bleak places. Rickets had also been seen in foals not getting enough milk, or where the mother was being worked. It had also been seen in the hog. These facts were sufficient to show that the same changes follow in animals and children when placed under similar conditions as to air and food. Another conclusion he drew was, that as syphilis was not known in animals, it had no connexion with the production of rickets. In reference to the results obtained by giving lactic acid to young animals, he thought that too much stress should not be laid upon them, for probably similar effects would follow the administration of many other extraneous matters; thus Guérin fed young dogs on flesh exclusively, and produced rickets.

The meeting then adjourned.

CLINICAL SOCIETY OF LONDON.

Stretching of Facial Nerve for the relief of Spasm of Facial Muscles.—*Myxœdema.*—*Persistent Gyrate Erythema.*

THE ordinary meeting of this Society was held on the 12th inst., Dr. E. H. Greenhow, F.R.S., President, in the chair. The subject of nerve-stretching for the relief of facial spasm was raised in a paper by Dr. Sturge and Mr. Godlee; and Mr. Croft related a case of division of the infra-orbital nerve for neuralgia. A paper on myxœdema

was read by Dr. Duckworth, and typical cases shown by Drs. Sémon and Hadden. Dr. T. C. Fox read a paper on a peculiar form of persistent erythema.

The following is the abstract of a paper on "Stretching the Facial Nerve for the relief of Spasm of the Facial Muscles," by Dr. ALLEN STURGE and Mr. GODLEE:—The patient, a lady of seventy-two, had been sent to Dr. Sturge by Mrs. Garrett-Anderson. She had enjoyed good health until the death of her husband, six years ago; after this her nervous system suffered much; she had fits of depression and debility, and before long twitching began round the right eye, extending subsequently to all the muscles supplied by the right facial nerve. She had gone through various courses of treatment without result, and she finally consented to have the facial nerve stretched. This operation was performed by Mr. Godlee on July 20th by means of an incision behind the ear, from the level of the external meatus nearly to the angle of the jaw. The sterno-mastoid and the parotid glands were pulled in opposite directions, exposing the upper border of the digastric, close to which the nerve was found as it emerged from the stylo-mastoid foramen. The nerve was raised on a hook, and pulled with moderate force; after a few such pulls the right side of the face was completely paralysed. The wound was dressed antiseptically, and the wound healed without a drop of pus or the slightest constitutional disturbance. The face remained paralysed for two months, and for some days after the operation there was a good deal of pain on the right side and also in different parts of the head, which returned at intervals during these two months. When seen on Oct. 19th, three months after the operation, the face at rest was nearly symmetrical on the two sides, but there was still a good deal of deficiency of movement in the muscles on the right side. She was, however, rapidly improving, every week making a considerable difference. The operation has now been performed five times, three times in Germany by Baum, Schüssler, and Eulenberg, once in America by Dr. James J. Putnam, the present case being the first operation of the kind in England. In all these cases there was temporary paralysis after the operation, varying from two weeks in Baum's case to five months in Eulenberg's. It was remarkable that in every case in which the facial nerve had been stretched for spasmodic tic the operation had been successful, whilst in several cases of spasmodic affection of other parts, as of the arm, &c., stretching the nerves of the part had produced no good effect. In these latter cases the spasm had usually been of an elaborate character, allied rather to chorea; whereas the former is a simple incoördinated spasm of all the muscles supplied by a single nerve. This latter character would indicate a lesion in the centre, from which the facial nerve takes its immediate origin—i.e., the medullary centre, whereas the former would point rather to a lesion in a coördinating centre higher up in the cerebro-spinal axis. Stretching the nerve certainly produces an immediate effect upon the nerve trunk itself, and it probably also produces a remote effect upon the nerve centres, which effect would be greater upon the lower centres, such as that for the facial nerve in the medulla, than in those further removed, which are supposed to have to do with coördination. In all cases where nerve-stretching is employed for spasm it will be very important to note whether the spasm is of the simple or coördinated variety, with a view to ascertain its relative value in the two varieties. The operation is rendered difficult on the living subject by the depth of the nerve and the constant trickling of blood into the wound. The operator should therefore secure a good light and efficient assistance. The posterior auricular vein may very likely be cut in the first incision, and the posterior auricular artery at any period during the dissection. No vessel of any consequence is, however, likely to be injured if the wound be not carried more deeply than the digastric muscle; should this level be passed, the surgeon will find himself in dangerous proximity to the internal jugular vein.—Dr. BUZZARD said that the plan introduced by von Graefe, of pressure over a branch of the fifth nerve, often succeeded in arresting spasm of the facial muscles; and division of the twig would often stop the spasm for a long time. He had had one such case under his care some years ago. In another case the

irritation of the facial nerve appeared to be due to accumulation of cerumen in the ear; for the spasm ceased on removal of this. The constant current was, however, also used in the case. He thought that it was fair to conclude that the seat of derangement was in the medulla. He had had no experience of nerve-stretching in these cases; but he had under his care in hospital at present a man who was the subject of most severe facial neuralgia. The supra- and infra-orbital nerves were submitted to stretching, and the pain was remitted for six weeks. On its recurrence the nerve-stretching was repeated.—Dr. WALSHAM had successfully stretched the infra-orbital nerve in a case of epileptiform neuralgia early in the present year; there had been no recurrence of pain. In considering the manner in which nerve-stretching operates in such cases, he had arrived at a conclusion different from that of Dr. Sturge, believing that it produced an alteration in the nutrition of the nerve-trunk, from the nerve being separated from its sheath. He founded this hypothesis on the fact that experiment on the dead subject showed no alteration in the centre from forcible stretching of the nerve; that in animals no effect was produced unless the nerve was injured; and that the theory of shock was insufficient to account for the results of the operation.—Dr. STURGE, in reply, said that pressure was made on a branch of the fifth nerve with no effect on the spasm. The patient had been under several eminent neurotic physicians, and was anxious to have something more done; so Dr. Sturge did not pursue any other line of treatment.—Dr. GODLEE said they hoped to record the condition of the patient at the close of the session. In reply to Mr. Walsham, he said that he was doubtful whether in the ordinary procedure of nerve-stretching the nerve could be separated from its sheath. He had a few days before treated another case of facial spasm in the same way. In that case the spasm was bilateral, but greater on the left than right side. He had seen many physicians and surgeons, and all possible sources of irritation had been inquired into. Cold increased the spasm. As there was a tender point on the left supra-orbital nerve, he had previously divided this nerve, but without result.—Mr. CROFT related a case in which, three years ago, he was asked by Mr. Liebreich to cut down on the infra-orbital nerve. The patient, who had suffered from most severe facial neuralgia with spasm for six years, was a native of Adelaide, and went to Hamburg to be under the care of Dr. Oscar Liebreich, whose brother was staying with him at the time. They both agreed that excision of a portion of the infra-orbital nerve should be done, and the patient came over to London. Mr. Croft excised five-eighths of an inch of the nerve, and also stretched it. The patient recovered very quickly, and five days after the operation left for Australia. For a time the pain was completely subdued; then it recurred with some spasm. At the end of six months he had an attack of gout with another attack of neuralgia, after which he was free from pain for another six months, when it again recurred. Mr. Croft, in reference to Dr. Sturge's view, could not admit that the disease was central in these cases. He referred also to the perfect relief afforded by excision of the bulbous ends of nerves in a stump of the leg, followed by stretching. The patient had suffered from great pain in the stump and spasm of the knee.

Dr. DYCE DUCKWORTH read notes of Two Cases of Myxedema, and exhibited the patients. Case 1: A stout woman, aged forty-seven, admitted into St. Bartholomew's Hospital in August last. She was a native of Birmingham, but had lived in London for twenty-five years. Had had nine children and several miscarriages. No syphilitic history. Her complexion was fair, and her hair a light-red. The skin of the face was puffy (especially eyelids and lips) and waxy-looking, with the exception of patches of vascularity over the malar bones. The face, scalp, and left shoulder presented several moles, acquired and not congenital, to which Dr. Duckworth drew attention, having seen similar moles in eight or nine cases of the disease. The thyroid was small; the integuments of trunk and limbs were swollen and puffy. The mucous membranes were anæmic, and the blood somewhat of damask rose tint. The hands were large and clumsy; thoracic and abdominal organs seemingly natural, but action of heart was feeble, and pulse generally under 60; appetite capricious; occasional nausea and vomiting; constipation; catamenia had ceased for six months; urine, sp. gr. 1015 to 1022, free from albumen and glucose. The physiognomical features suggested chronic renal disease. Speech was slow, voice harsh and snuffing. She was very slow in expressing her ideas; her walk was deliberate and

shuffling, gait waddling. She was easily thrown off her balance, and never ventured to cross the street. Movements were slow, but brisker in warm weather. The least chill was acutely felt. The temperature of the left side of the body was lower than that of the right, observations for eighteen consecutive days showing variations from 93°4' to 97°8' on the left side, and 95°4' to 99°4' on the right. The swelling began three or four days ago. She had led an unhappy life with a brutal husband, and been much exposed to blows and ill-usage. Seven years since she was in Guy's Hospital suffering from paresis of the right leg, with anaesthesia about the ankle. She improved under electrical treatment and tonics. During her stay at St. Bartholomew's Hospital she suffered much from cold, and was always dull and morose. Stimulants readily stupefied her. She took various tonics and arsenic, and as much good food as possible, but no improvement resulted. There was no albuminuria at any time. Case 2.—A married woman, aged forty-six, born at Retford, but had lived for twenty years in Clerkenwell. She was well grown, with dark hair, sallow complexion, vascular patches over malar bones, and puffiness about the eyelids. The facial aspect denoted chronic nephritis. There was one mole on the left cheek. The expression was dull and languid. The thyroid body seemed natural. The hands were "spade-like." There were slight bronchial catarrh and constipation. Pulse 80. Legs oedematous, the right pitting more than left. Urine: sp. gr. 1005, acid, not albuminous. The catamenia had become irregular this year. She had noticed herself becoming stouter for eight years. Two or three years ago she found she could not ply her needle so freely as formerly. Her speed and general movements have become slower. She could walk fairly well if not hurried, but was very timid in the streets. Sometimes she fell down, and had difficulty in preserving her balance. She took a long time to dress herself. There was marked susceptibility to cold and changes of temperature. Temperature: in right axilla 99°4'; in left 97°2'. She complained that her food did not taste properly. She had good health till eight years ago. There was no family predisposition. The case presented many of the well-recognised features of the disorder, and seemed to be progressing slowly. No treatment appeared to control or modify the cachexia in any noteworthy degree. Dr. Duckworth added that the connexion of acquired moles in such cases was interesting. He had found them now in eight or nine cases, and pointed out the concurrence of defective mental conditions with moluscum fibrosum as suggestive of the association of moles with the defective mental powers in myxoedema.—Dr. SÉMON had brought a case of myxoedema to show to the Society. In addition to the typical symptoms she presented a marked falling off of hairs from all parts of the body. Her teeth also showed a tendency to break off, and there was a puffy condition of the gums. She suffers from loss of memory and hallucinations. The history of the case pointed to a central rather than peripheral nerve-disorder—the symptoms starting from an injury, followed by pain in the head. In this case, as in so many others, there had been frequent pregnancies. She had had fourteen children and seven miscarriages. Dysphagia had been noted in some cases. In this one there was no difficulty in passing an œsophageal bougie. There was no diminution of sensation in the palate or pharynx. The laryngeal mucous membrane had a glistening appearance, and the vocal cords were notably anæmic.—Dr. HADDEN had brought a case at the request of Dr. Ord. This patient showed a brittle condition of the nails. The quantity of urea excreted was also deficient. He had recently seen a case in a male subject, all others on record being females. He thought the condition pointed to some profound lesion of the sympathetic.—Dr. DUCKWORTH said that he had come to the conclusion that the disease was one of central origin, due to trophic derangement. In reply to Dr. Theodore Williams, he said that a few of the temperature-observations were taken with the surface-thermometer; but most of the temperatures recorded were axillary.—The PRESIDENT suggested that Drs. Sémon and Hadden should put their cases on record in the Society's Transactions.

Dr. T. COLCOTT FOX described to the Society, and exhibited drawings of, two unique cases of Persistent Gyrate Erythema, affecting the two elder members of the same family in a precisely similar manner, in whom it had existed fourteen and sixteen years respectively—i.e., since they were about four years of age. The patients were never entirely

free from eruption, but every few months they were subject to acute outbursts, lasting from ten days to six weeks, which covered the greater part of the trunk and upper limbs, but especially affected the shoulders, the buttocks, and thighs, and the eruption was always associated with intolerable irritation. There was no clue to the cause in the family or personal history. The festooned eruption always began by erythematous papules of the size of millet seeds. These quickly subsided, leaving an enlarging annular erythematous bordering, which always preserved an equal breadth as the erythema subsided within the border in equal ratio to the advance of its outer border. These circles fuse with neighbouring ones, to form the gyrate figures, which gradually die away in a week or ten days, leaving a good deal of pigmentation. The desquamation is peculiar, inasmuch as it is very rapid and is quickly thrown off, leaving only a ragged white bordering attached to the inner edge of the erythematous rings. The eruption was clearly of the erythematous type, and such festooned figures are quite in keeping with what we know of the evolution of many erythemata. There was no fungus present, and no evidence of hereditary syphilis. The aspect presented by the eruption was a most unusual one, and had excited much interest in several skin clinics of the metropolis. The great peculiarity in the case, however, was its extreme persistence.—Dr. CARRINGTON had recognised the male patient as having been under Dr. Pye-Smith's care at Guy's Hospital. Many remedies were tried, and finally arsenic, which led to marked improvement; and Dr. Pye-Smith thought the eruption therefore a form of psoriasis.—Dr. F. TAYLOR said the case had also been under his care at Guy's Hospital about four years ago. The eruption then appeared rather more highly coloured than as represented in the drawing by Dr. Fox. Only temporary relief was given by treatment.—Dr. CAVAFY thought the subsidence of the rash under arsenic lost in importance as an element of diagnosis from the fact stated by Dr. Fox, that it had occasionally subsided spontaneously. He agreed with Dr. Fox as to the chronicity of some of the erythemata, one instance of which is that of the so-called "urticaria pigmentosa."—Dr. FOX said he had only the patient's statement to go upon as to the effects produced by different remedies. Urticaria pigmentosa was a good instance of a chronic erythematous rash.—The PRESIDENT mentioned a case of urticaria pigmentosa which persisted for five years, and was unaffected by treatment.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Recurrent Epistaxis. — Diagnosis and Treatment of Whooping-cough. — Pauper Lunacy Laws and Medical Relief.

At the meeting on the 15th inst., F. J. Gant, Esq., President, in the chair—

Mr. SPENCER WATSON read a paper on a Case of Recurrent Epistaxis of twenty months' duration. The patient was twenty-nine years old. He suffered from headache and marked constipation; he had no gouty tendencies or other constitutional disease. The headaches and epistaxis were attributed to the breathing consumed air over and over again in the ill-ventilated room in which he slept, and to the straining at stool consequent on the difficulty of defecation. The change to a well-ventilated bedroom, and the use of perchloride of iron solution as a douche, were followed by very rapid improvement, and at length by the total cessation of the habitual bleeding. Ergot administered internally had entirely failed, though given in large doses.—Mr. PEARCE GOULD remarked on the difficulty often met with in treating these cases, and inquired whether belladonna (which, given in small doses, had cured a case that had resisted plugging and perchloride of iron) had been tried internally. He thought better success attended plugging of the anterior nares with a piece of sponge steeped in solution of perchloride of iron, than the more common and less acceptable method of plugging the posterior nares.—Mr. WORDSWORTH referred to a case in which he had ineffectually plugged both posterior nares in an elderly gentleman. The hæmorrhage was subsequently arrested by the

administration of the oil of turpentine in small doses.—Dr. JAGIELSKI advocated the more frequent use of internal remedies. He had found small doses of *nux vomica* frequently repeated to be of service.

Dr. R. J. LEE then read a paper on the Diagnosis and Treatment of Whooping-cough. The early history of this singular malady was briefly traced from the year 1678, when for the first time the name appeared in the bills of mortality, to the present time; and the question was raised whether the disease had really increased of late, or had only recently been more accurately diagnosed. His own observations extended over several years, and the chief points of diagnosis worthy of attention were the frequency with which young children and infants were attacked without the symptom of the "whoop" occurring, so that many infantile disorders really due to whooping-cough were referred to some other cause. The infectious nature of the malady and the period of incubation, deduced from a series of twenty-one cases, were shown to be easily estimated in hospital practice, and the conditions under which adults contracted whooping-cough a second time were pointed out. The train of symptoms in infants was detailed, and the frequency with which serious and often fatal diarrhoea occurred was mentioned. As to treatment, it was urged that there were probably good reasons for inquiry into the popular belief, that the waste products of the distillation of coal had a beneficial effect in relieving the cough. Singularly good results were obtained by the inhalation of carbolic acid. The trial of turpentine, creasote, &c., was recommended, as the use of these drugs was stated to have been attended with considerable success. No specific value could be claimed for any of the numerous remedies which had been at different times extolled; he said that circumstances must direct the appropriate use of them in different stages of the disease. There was little need to discuss the view that the symptoms were referable to nervous derangement, while the question of law to prevent the spread of the disease remained unanswered.—Dr. JAGIELSKI had found *drosera* a valuable remedy, especially in those cases which were accompanied by vomiting and dyspeptic symptoms.—Mr. SPENCER WATSON asked whether diet was important in the treatment, for he had seen great improvement follow the substitution of milk diet for an ordinary diet of meat.—Dr. MAIR had found quinine combined with belladonna useful, and also a blister to the nape of the neck in many cases. He confirmed the statement as to the frequent absence of the whoop in the cough, which, however, had other characteristic features.—Mr. NAPIER testified to the value of the antiseptic treatment advocated by Dr. Lee, which was also of advantage as limiting the spread of disease.—Dr. LEE, in reply, said he thought belladonna superior to *drosera*, but would give this remedy a fair trial. The question of diet was important, but in the case of young children there was little choice; and in infants he never departed from simple milk food. The peculiarity of the cough in infants was of value in diagnosis, and was characteristic although the whoop might be absent. The best method of volatilising carbolic acids and other agents would be the subject of a future communication.

Dr. BOYD read a paper on Pauper Lunacy Laws and Medical Relief, having reference to the delay under the Pauper Lunacy Act in the admission of patients to asylums, to the facilities given by the Acts to crowding them with aged, infirm, and incurable paupers, and to the necessity of reversing the law, and instead of having the asylums, as at present, auxiliaries to union infirmaries, applying portions of workhouses and vacant prisons (after making suitable alterations in them and placing them under the jurisdiction of the justices) for the reception and classification of incurable cases of insanity, thereby saving the expense of further additions to those costly institutions, lunatic asylums. *Medical relief* to be separated from *poor relief*, and given to the poor of the working classes, without pauperising them, as so efficiently done in France (where no poor law exists)—e.g., at Le Salpêtrière and La Bicêtre, which the parochial infirmary of St. Marylebone very much resembled before it was put under the Poor-law Board and at the time that it was recognised as a medical hospital. Such an institution, affording an opportunity of studying every form of disease, should be opened to pupils for clinical instruction and to medical practitioners engaged in pathological investigations.—Dr. CHRISTIE (Ealing) thought a full discussion of this subject to be much required; it had a political and public aspect as well as a medical.

A sub-committee upon the question—composed of Dr. R. Boyd, Dr. R. J. Lee, Dr. Christie, and the hon. secs.—was recommended to the consideration of the Council.

Reviews and Notices of Books.

Osteotomy; with an Inquiry into the Etiology and Pathology of Knock-knee, Bow-leg, and other Osseous Deformities of the Lower Limbs. By WILLIAM MACEWEN, M.D., Surgeon and Lecturer on Clinical Surgery, Glasgow Royal Infirmary. London: J. and A. Churchill. 1880.

FOR Dr. Macewen there is but one disease producing the bony deformities in childhood and early life, and that is rickets. He refuses to recognise other causes of softening of bones, or irregularity in growth. From his own observation he gives three examples of well-marked rickets occurring at puberty, and he considers that the disease may be induced at any time during the growth of the body by any causes of general malnutrition. Of all the bony deformities of the lower limbs knock-knee is for many reasons the most interesting, and it receives the fullest and most careful treatment at Dr. Macewen's hands. From his measurements he concludes that the deformity is usually the product of many factors, the most constant of which is an inward curve of the lower end of the diaphysis of the femur, noted 120 times out of 166 observations; next in frequency and importance is abnormal elongation of the internal condyle of the femur, in 84 per cent. of cases, the increase in length varying from one-half to one inch and a quarter; the condyle is often also enlarged inwards; in about 30 per cent. of cases there is an irregular growth of the tibia also, but this is usually of much less influence in determining the deformity. The different and now rather numerous operations for its cure are described and discussed, and the reasons why supracondyloid osteotomy is preferred are fully stated. The main advantages of this method are, that it does not open nor interfere with the articulation of the knee in any way, and that it deals directly with the most constant alteration in the shape of the femur. Dr. Macewen is a disciple of Professor Lister, and is at pains to point out that osteotomy cannot be done so thoroughly subcutaneously as tenotomy, and that antisepticism has done for it what subcutaneous surgery did for tenotomy. Although in many instances air is effectually excluded from the wound, yet there are others where this cannot be done; and the results of compound fractures teach us that even where the wound in the soft parts is a clean incised one antiseptic surgery holds out the most certain hope of perfect success. At any rate, Dr. Macewen's success, from the point of view of recovery from the operation (the only results given in the book), has been signal. He has operated on 330 patients, performing 835 osteotomies, and has had three deaths, one from tubercular meningitis, one from diphtheria, and one from pneumonia, which had set in prior to the operation; in eight cases only was there any suppuration, and in seven of these the cause was known to be avoidable. Where several osteotomies are demanded in the same patient—and Dr. Macewen speaks of having made ten—they have all been done at one and the same time. The book might have been with advantage relieved of repetition in several places, but we confidently recommend it to the study of all interested in the removal of these common but often disastrous deformities.

Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects, Vol. I. A—Berlinski. With List of Abbreviations of Titles of Periodicals indexed. Washington: Government Printing Office. 1880.

IN 1873 Dr. J. S. Billings published a catalogue of the Library of the Surgeon-General's Office (United States

Army) in two large volumes. In the following year a third or supplementary volume, containing anonymous works, reports, transactions, and periodicals, was issued. At that time the library contained 25,000 volumes and 15,000 single pamphlets, and the catalogue gave the enormous number of 50,000 titles, exclusive of cross references. Since then the collection has grown largely, and is now, both as regards quantity and quality, one of the finest in the world.

The Index-Catalogue is practically an entirely new work. It is formed after a different plan from that of the earlier catalogue, and includes titles of both authors and subjects, arranged in dictionary order in a single alphabet. This plan, it would seem, was selected after some discussion and deliberation as being, upon the whole, the most serviceable to those who were likely to use the catalogue. To the pure bibliophile separate catalogues of authors and of subjects would, of course, be more convenient, but to the majority of those who will most frequently need and use the work the mixed form will, perhaps, be more acceptable.

Of the amount of labour and time bestowed upon the preparation of the work some idea may be gained when it is stated that under the subject-headings are included the titles of most of the original articles in the medical journals and transactions contained in the library. Under the word "Albuminuria," for instance, there are over fourteen closely-printed columns of references to separate works on this subject, and to original articles in various periodicals. "Amaurosis" has eighteen columns devoted to it; "Amputation" seventy columns; "Anatomy" seventy-four; and "Aneurism" no less than one hundred and thirty columns. These references are not, however, indiscriminately massed together, but are systematically arranged and classified. To take the last-named word, "Aneurism," as an example. There is first a large number of references to works and articles dealing with the subject of aneurism generally, and then come other references under various headings in alphabetical order, as *circoid*, *diagnosis*, *dissecting*, *false* and *traumatic*, &c. &c., and, finally, a very complete list of references to aneurism of special arteries. There are, for instance, not less than thirty-nine columns of references to aortic and abdominal aneurisms, and nearly twenty columns to popliteal aneurism. Furthermore, a glance at the pages of the Index-Catalogue gives a very good indication of the age and extent of literature of any particular subject. The references to the literature of the comparatively recent subject of antiseptic surgery occupies ten columns, exclusive of independent and special references to abscess, ligature of arteries, ovariectomy, and other matters relating to antiseptic surgery. There are nearly six columns of references to the interesting but antiquated and exploded subject of alchemy. This list contains the titles of thirty-seven different works, some very scarce, by Glauber. It is, however, necessary to bear in mind the caution given by Dr. Billings in the preface. Though often of the greatest value in indicating the writings of an author and the chief editions, the catalogue is not a complete medical bibliography. It is a catalogue of what is to be found in a single but thoroughly representative collection of medical works, and should only be used as such.

The combined completeness and accuracy of the catalogue is the best monument to the intelligence, industry, and attainments of Dr. Billings and his assistants. Though the first volume does not go beyond the "Berlinski," it includes 9090 author-titles, representing 8031 volumes and 6398 pamphlets. The one thousand pages comprise also 9000 subject-titles of separate works and pamphlets, and 34,604 titles of articles in periodicals. An alphabetical list of medical periodicals employed in the Index-Catalogue occupies 126 pages.

The prospective labour still before the compilers of this valuable work is indeed so gigantic, and the standard of those who have undertaken it so high, that the accomplishment seems almost unattainable. Meanwhile, Dr. Billings and his assistants have earned the sympathy and gratitude of every lover and student of medical and surgical literature.

[THE name of the publishers—Messrs. John Smith & Co. 52, Long-acre—was inadvertently omitted from our notice last week of the "Physician's and Surgeon's Visiting List, Diary, Almanack, and Book of Engagements for 1881."]

THE TREATMENT OF GENU VALGUM.

To the Editor of THE LANCET.

SIR,—I crave permission to make a few remarks on the above subject, in amplification of those contained in your report of the discussion at the Royal Medical and Chirurgical Society on Tuesday Nov. 9th.

I would first wish to modify a little what I am reported to have said about flat foot: "Flat foot was by no means often met with;" *add*, as an *antecedent* condition to genu valgum: when it occurs, it is the direct *consequence* of the genu valgum, and results from the weight of the body being thrown unduly on to the inner ankle. Then in comparing the two operations, osteotomy and tenotomy, I wished to say, in proportion to our knowledge of how to avoid surgical accidents, I did not consider osteotomy more dangerous to-day than was tenotomy at the time it was first introduced into surgical practice.

The object of the paper was to altogether discountenance forcible straightening and osteotomy as means of treatment for this deformity and to advocate tenotomy. Mr. Brodhurst will, I think, fail to secure many followers, for it is hardly reasonable that one and the same method of treatment can be successful in a deformity which may depend on very different pathological lesions. Although an advocate of osteotomy in *certain cases*, I do not range myself among those surgeons, referred to by Mr. Brodhurst, who operate "in every case of genu valgum, even when the deformity was yet very slight." I was disappointed that a mere statement was advanced in support of such a sweeping assertion instead of facts. Fortunately it matters little, for the opinion of the majority in this matter, as others, will ultimately prevail.

Osteotomy is one of the many outcomes of Listerism, without which it would be a very formidable operation. Even with it, it is a serious matter; but so is the deformity, and it unfortunately occurs most extensively in that class of life where its ill effects are most severely felt. Owing to the length of time required for the proper carrying out of Mr. Brodhurst's method, it is inapplicable in a considerable number of patients, and then the question between osteotomy or nothing has to be decided. On the other hand, in cases where the internal condyle has become longer than normal, I fail to see how any plan of treatment can be efficient which does not take this circumstance into consideration. Unless the condyle be shortened in some way the deformity can only be overcome by separating the external condyle from its corresponding tuberosity, thus seriously weakening the joint.

I will again urge that the greatest incentive to osteotomy has been the utter insufficiency of the older methods in a certain class and in a certain number of cases.

It was suggested that no statistics of osteotomy had been published. I venture to believe that detailed statistics of the older method by tenotomy would be a great deal more useful, as well as suggestive. And I further think the statement would be truer of tenotomy than of osteotomy.

I remain, Sir, &c.,

ROBERT W. PARKER.

Old Cavendish-street, W., Nov. 15th, 1880.

THE first prize of 500 dollars, offered by the National Board of Trade of the United States of America for the best essay and draft of an Act to prevent injurious Adulteration and regulate the Sale of Food, without imposing unnecessary burdens upon commerce, has been awarded to Mr. G. W. Wigner, F.C.S., F.I.C., of London, honorary secretary of the Society of Public Analysts.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 20, 1880.

IF Dr. HABERSHON and Mr. COOPER FORSTER will forgive our appropriating much of the phraseology of their recent letters to the Governors of Guy's Hospital, we should like to say:—For some time past it has appeared to us *impossible* that they and other men of spirit connected with that institution could continue to hold their offices as physicians and surgeons. It is easy to understand that “the pleasure and pride” every member of the medical staff must have “formerly” found in his work at “a hospital which has hitherto been held in the highest honour throughout the world,” together with “long-cherished associations and a natural desire not to separate themselves from their colleagues” during a period of difficulty and disaster, may have led these gentlemen to defer their resignations, though we cannot discover the grounds for their “hope of a speedy issue to the present miserable strife.” At the same time recent events in this struggle proceeding at Guy's could not but convince Dr. HABERSHON and Mr. COOPER FORSTER that “the chances for their hospital of wise and enlightened government are still very remote.” We will not carry the appropriation further. Some of the expressions selected by the senior surgeon for the setting forth of his views are scarcely those we should ourselves have chosen. Meanwhile it is matter for general congratulation that the two senior members of an insulted and discredited staff have ceased to sanction by their official connexion a system of hospital management which, whether regarded from the utilitarian or the politico-religious standpoint, is wholly impracticable, and, as it has been repeatedly described in these columns, both mischievous and absurd—ridiculous in its economic aspect, and injurious to the interests and common safety of the sick poor. It would have been a calamity as well as a scandal if, misled by a false representation of the state of public feeling and the mature opinion of their profession, Dr. HABERSHON and Mr. COOPER FORSTER had longer delayed the discharge of a self-evident duty to themselves, their colleagues, and the community. It would have been incomparably better if, waiving minor considerations—which indeed were comprehended in the greater and graver question of principle—the seniors had retired some weeks ago, throwing the onus of a choice of policy on the staff as a whole. We recognise and understand the feelings that prompted the view they took, but it has not been possible, and it is still impossible, for us to approve it. A more spirited course would, we are convinced, have saved both the medical staff and the Governors of Guy's Hospital from most disastrous blundering in what is, in truth, a much more serious business than those actively concerned in the imbroglio seem to have perceived.

For ourselves, it may appear that we have taken, and continue to take, a view of this most unhappy controversy which is at once much more urgent and critical than that adopted by our contemporaries. It has been for us a repre-

sentative struggle throughout, and with unfeigned regret we have seen that the medical staff did not so regard it. A narrow view of policy has been urged upon, and adopted by, the physicians and surgeons of this great metropolitan hospital; whereas a broad view and a generous and high-minded concern for the principles at stake in the controversy were required, and alone permissible. Our view has not been the popular one; but it has, we are persuaded, and will hereafter be proved to have been, the only view consistent with the interests of the sick poor, and the dignity and usefulness of the profession we claim to represent. Nothing which has recently occurred in connexion with the lay management of Guy's Hospital has changed the *real* aspect of its affairs. Those who are striving to find an excuse for changing their views and amending their counsels, will not find a footing of sound argument to go upon. If it is right for Dr. HABERSHON and Mr. FORSTER to resign now, it was still more incumbent upon them to take that step a month ago. The charges made in the letter which was awkwardly indited and still more awkwardly withdrawn some weeks since are repeated, and in terms certainly not less irritating than those for which something like an apology has been formally tendered. The “offence” once condoned and forgiven has been again committed. What are we to understand? There is only one interpretation possible; the opinion of the seniors has not been supported by the staff as a whole. The original letter, which was made the ground for requiring the resignation of Dr. HABERSHON and Mr. COOPER FORSTER, expressed the mature judgment of the seniors. It was withdrawn under the pressure of the juniors, to avoid a general break-up. The seniors have now thrown off the yoke, and are free to tell the President, Treasurer, and Governors, what they think of them and their policy.

It was a blunder of policy to withdraw the whole of the original letter. It was not a carefully written or very temperate letter, but it told the truth. The system of management at Guy's Hospital has been, and is, *mischievous*. We do not share the implied opinion that those who are responsible for that system have been actuated by personal motives. We believe the most crooked policy is often adopted, and the worst disasters are brought about, with the best of good intentions and the most upright of philanthropic purposes. Self-sufficiency and fussy ignorance will wreck the most earnest and honest of enterprises. We can well believe the President, the Treasurer, and every one of the Governors of Guy's Hospital, to have been animated by sincere and benevolent aspirations for the well-being of the institution entrusted to their care; but that their policy has been mistaken is at length, as it ought to have been months ago, evident to everybody except themselves. Even those who flatter and essay to support them know they have shown a strange want of tact, and acted with mingled irritability and weakness. These considerations do not, however, in the smallest degree, or in any other way, affect the question at issue, which is simply this: Who are the proper persons to organise and administer the working system of a medical institution? The obvious, and we take leave to say the *only* rational, answer, is: of course the medical men officially connected with and directly responsible for the charity. They, and

they alone, can possibly know what is wanted to make a hospital effective for the benefit of the sick poor, and they must be the arbiters in every question of administration which can possibly arise. If the Governors of Guy's Hospital are wise, they will adopt this common-sense view of the matter, and, waiving their egotism, will embrace the opportunity offered by the resignations of Dr. HABERSHON and Mr. COOPER FORSTER for a reconsideration of the whole question, with a view to placing everything on a new and fair footing. The crisis has come, and it remains to see whether those most actively concerned in its production are sufficiently alive to its dangers, and self-sacrificing enough, to make the necessary concession. The inner truth about this vexatious business at Guy's lies in a nutshell. There have been faults of method and temper on all sides. It is inconceivable that men of position and character like the majority of the Governors can have wilfully done wrong. It is foolish to think they have, and fatuous to charge them with having, done so. Unfortunately, however, the Governors have been misled and ill-advised. As honourable men we anticipate that they will now put themselves right. As regards the conduct of other of the Governors and their agents, it is unbecoming the self-respect of representative members of an enlightened profession to quarrel with them. Mistakes have been made in this respect, and the time has come to repair the evil and to adopt a policy at once more sagacious and influential because less irritating.

Meanwhile what will this hospital medical staff do? The seniors have, tardily perhaps, discharged their duty. Will the staff accept the further humiliation of having outsiders placed at their head? Will outsiders be found willing to be placed in that "bad eminence"? It must not be supposed that we have no sympathy with the physicians and surgeons of all ranks attached to the hospital and its school. It is impossible not to feel that Fate has been wondrously cruel to them. The predicament in which they are now left must excite compassion, though it is one in which their indecision and want of unanimity have placed them. We have, indeed, a lively sense of the manifold difficulties that beset the path of duty which lies before our brethren at Guy's. The way may lie through troubled waters, but these will be less harmful than the muddy path which the staff has for some time past been painfully following.

It is too early yet to speak with any approach to certainty of the results likely to accrue from the formal discussion on Rickets at the Pathological Society. The disease is so widespread among us, so constantly recognised, especially by out-patient physicians and surgeons, and its more characteristic manifestations are so familiar even to the laity, that it would seem to be a disease peculiarly fitted for debate, and one on which a good deal of light might thus be thrown. But as far as the discussion has at present proceeded this hope seems scarcely likely to be realised. Dr. HILTON FAGGE disclaimed any intention of advancing new theories or recording new facts, but his paper, which we publish to-day, was no doubt as able a presentation of some of the problems demanding attention as the subject allowed. It indicates pretty accurately the lines along which the subsequent discussion will travel. Dr. FAGGE

has done well to raise the question, "What is rickets?" No doubt it is a general, not a local disease, although its more serious symptoms are commonly changes in the bones. But by what general or local, other than bony, changes can we recognise the disease? Is a marked susceptibility to catarrh a cause or a symptom of the disease? Are the changes in the spleen and lymphatic glands, pointed out by Sir W. JENNER, peculiar to rickets, or merely common to any condition of general ill-health in young children? And, again—a point to which Dr. FAGGE did not allude—to what age is rickets limited? Dr. FAGGE spoke as if it were merely a disease of childhood. Is it not rather a disease met with at all periods of growth? Have not all surgeons met with children at puberty suffering from general malaise, muscular and osseous pains—growing pains as they are popularly called, and osseous deformities of the growing ends of bones, especially those producing genu valgum? And is not this as truly "rickets" as the disease so common in the first two years of life? From such questions as these we are perforce led to ask if there be a distinct disease—rickets—at all? In growing bones certain peculiar changes are no doubt observed, but are they not the simple results of general malnutrition of that particular tissue? The spleen and lymph-glands are other tissues specially active in childhood and youth. Are not the results of general bad health—the absence of perfect robustness and vigour, as Dr. FAGGE would call it—in these tissues those that have been supposed to be characteristic of rickets? If, in answer to this, we are told of the three special symptoms of rickets that Dr. FAGGE agrees with Sir Wm. JENNER in laying important stress upon, we are bound to state that no one of them is beyond criticism. Do we not constantly see the profuse sweating said to be characteristic of rickets in other instances of general weakness—phthisis, convalescence from acute specific diseases? The restlessness, too, is found acutely produced by rapid hæmorrhage, or more slowly manifested in fevers and other exhausting maladies; while the aching pains and tenderness in muscles are too frequently seen during convalescence from other diseases, or in their acuter stages, to warrant our attaching great weight to them. Dr. FAGGE refuses to recognise sickness, diarrhoea, and tumid belly as a part of rickets. We now know that the medulla of bone is of considerable importance in the function of hæmopoiesis, and the changes that take place in it may therefore be supposed to be peculiarly active during pregnancy, when a great strain is thrown upon the mother's blood, and its condition then bears some resemblance to that of the "intermediate zone" of growing bones. And this actively changing medulla of pregnancy is found to be liable to a disease that, at any rate, bears some coarse analogies to rickets; for must we not see in the great increase of an unhealthy medulla in mollities ossium with deep-seated bone-pains a resemblance to the irregular development of the intermediary zone in rickets with so-called articular pains? And may we not go further and say that the so-called "strumous glands" so common before and just after puberty, when these structures are actively developing, are as truly "rickety" as the lymphatic glands mentioned by JENNER and DICKINSON? Have we not in them changes similar to those in the growing ends of rickety bones—

an irregular and excessive growth in place of regular development? To sum up, we would ask the question, *Is there such a disease as rickets at all?* Are not the changes and symptoms usually attributed to that disease the simple, common results of a state of general malnutrition in persons and on tissues in an active state of growth, having their close counterparts, if not exact analogues, in diseases of later life, and affecting rapidly growing parts? We have put it in the form of a query, for it hardly seems the time to dogmatise when the whole subject is under discussion, but there are other pieces of evidence that might be adduced in support of the affirmative answer to our question. One of these was prominently brought out by Dr. CRISP, who gave abundant and distinct evidence that rickets is not only a disease which may be met with in all vertebrata, but that in very many cases it has been produced artificially, by bad air or bad food, or cold or damp. Does not this fact mark off the bone changes as distinct from a special disease? Does it not clearly point to them as being the result of general ill-health, not requiring even one particular cause, but apt to follow the serious breach of any hygienic law by young animals?

The issue raised by Drs. BARLOW and LEES was narrower; and valuable as is their statistical investigation, it cannot be held to satisfy inquiry. The fact that fifty per cent. of children with cranio-tabes are the subjects of inherited syphilis does not prove that the syphilis is the specific cause of the bone change. What percentage of syphilitic children have cranio-tabes? And further, what proportion of such children develop afterwards the usual signs of rickets? Is the pathological change in cranio-tabes analogous to that in the ends of growing long bones, or to other syphilitic manifestations? Such questions as these must be answered before we can speak definitely as to the significance of this symptom. The widely-open fontanelles of tabetic crania are certainly not peculiar to syphilitic children, and the delayed ossification they signify may be merely the indication of a lack of perfect robustness, whether from syphilis, bad air, bad food, or insufficient clothing. On the pathology of cranio-tabes we much need enlightenment, and its elucidation will probably do much to set at rest the question Drs. BARLOW and LEES have opportunely raised. Much then is open for the subsequent speakers in this debate to deal with, and we may hope that answers will be forthcoming to these, and to the many other questions raised on Tuesday last.

THE English Church Union is fond of being in hot water. It is not content with having a controversy with the law courts and with the Reformation. It proposes now to have a controversy with the Hospital Sunday Fund. It lately passed the two following resolutions:—

“That the recent discussion at a meeting of the Hospital Sunday Fund Committee of the religious character of the management of a Convalescent Home is unquestionably beyond their province, and a subject with which, from their assumed unsectarian character, they are utterly incompetent to deal.

“That this meeting of churchmen and subscribers express their opinion that a repetition of such a discussion will prevent the clergy and laity of the Church of England from

supporting the Hospital Sunday Fund in their accustomed generous and hearty manner.”

The English Church Union, with much modesty, assumes in the second resolution the right to speak in the name of the clergy and laity of the Church of England. It is a matter of public notoriety that it has no right to assume so to speak. It is an intensely narrow society, and represents rather a sect in the Church of England than the Church of England itself. There is no reason to think that the Church of England at large, or the Nonconformist churches of the kingdom, in any degree misunderstand the real nature and spirit of the question that has lately been most intelligently and generously discussed in the Council of the Hospital Sunday Fund, and, so far, wisely settled. It will be wise in the English Church Union not to raise any questions as to the number of churches it represents, and as to the proportion between the sums such churches contribute to the Hospital Sunday Fund, and the amount they withdraw from it for the support of charities with an obvious ecclesiastical bias. This is scarcely the place for such questions and comparisons, but we will venture to say that the small party represented by the English Church Union has more to lose than the Hospital Sunday Fund by refusing to the Council of that fund the right to demand that proselytism shall not be recognised as one of the functions of a hospital, and that the opinions of religious patients shall be respected.

Even at the cost of losing the contributions of proselytisers, the Hospital Sunday Fund must secure the recognition of these principles. The great bulk of the members of the English Church and of Nonconformist Churches will agree with Professor MARKS that hospitals are not the place, and sickness is not the time, to disparage and to controvert the creeds of patients. For the present the Council of the Hospital Sunday Fund have acted wisely in trusting for the protection of patients to the fourth law of the Fund, which requires that all participating institutions shall be governed by a *Committee*. Any ordinary body of Englishmen will believe that a Committee “duly appointed”—i.e., elected by a body of subscribers of presumably various religious opinions—will see that proselytism is prohibited in a hospital professing to receive persons of all creeds. If this belief should be invalidated by experience, the Council of the Hospital Sunday Fund will have to enact a new law to this special end. We have it on the authority of the English Church Union that the Hospital Sunday Fund is unsectarian in its character. It is the very glory of the Fund, in the eye of the public, to be at once religious and unsectarian—to be raised by all Churches for the relief of suffering. But this very quality of the Fund is abused by the English Church Union, and regarded as involving “utter incompetence” to deal with faults in the religious administration of hospitals. The Hospital Sunday Fund may have to choose between the English Church Union and the general religious public who supply its funds. But if the Fund is to be maintained, there is no room to doubt how its choice must go. It is not to be tolerated that money coming from such sources is to be applied to grossly sectarian uses. It may suit the purpose of the English Church Union to pose as the advocate of religious freedom, and to represent the Hospital Sunday Fund as violating its “unsectarian character” in demanding respect for all creeds.

Such misrepresentation may do some harm to the Hospital Sunday Fund, and more harm to institutions like those of Clewer and Eastbourne. It is very easy even for ecclesiastical societies to do harm in this world. But the English Church Union will not long impose on the English public if the Council of the Fund have the courage and the intelligence to see the principles and the feelings that are at stake.

THE Indian Government has, in compliance with Dr. D. B. SMITH'S desire, published in full his explanation regarding the expenditure of the Medical College Hospital. We pointed out some time ago that, in justice to Dr. SMITH, this course should have been at once followed. We are now bound to express our opinion that the explanation does not in any degree modify the conclusions at which we arrived from the study of the official documents as originally published. It is a long, wordy, and, in many points, irrelevant document, and is mainly occupied with a defence of his conduct as principal of the Medical College, and, therefore, responsible for the management of the hospital. But this was quite unnecessary, as the Lieutenant-Governor had stated in his official minute that he "has never for a moment called in question the praiseworthy devotion with which the officers attached to these institutions have discharged their onerous professional labours. The Lieutenant-Governor fully appreciates their efforts to advance the cause of medical science, and to do all that science and skill can dictate to alleviate the sufferings of the sick under their charge." The question at issue between the Lieutenant-Governor and the medical officers in charge of the hospital was not as to the manner in which their professional duties were discharged, but whether these institutions were managed as economically as they should have been, and whether there was not a want of effective administration, "which added enormously to the Government expenditure, without, in many cases, benefiting the patients." Dr. SMITH enters into a long detail of the history of the hospital from 1866 to 1879, and gives extracts from the report of a committee appointed in 1870 to inquire into the scale of hospital diet, and he seems to consider it a sufficient defence of the administration that the control over the general expenditure "was in strict accordance with the existing regulations and orders of the Government," and that the expenditure was kept within the sanctioned limits. But he subsequently states that "the former dietary system of this hospital was, in my opinion, a cumbrous, faulty one. I never pleaded for its imperfections, and I have no desire to do so now. But I was not in any way responsible for its introduction. The system, such as it was, had received the assent of the Government long before I joined the hospital, and I had it placed in my hands as an approved system, and one which, according to regulation, was month by month submitted for audit." And, again, he says:—"I considered the system cumbrous and faulty. In making over charge to Dr. COATES I particularly brought to his notice the fact that I thought the whole system required revision, and I then begged him to bring its imperfections carefully to the notice of Government (as I myself should have done had I remained longer), with a view to the adoption of an improved system." These remarks of Dr. SMITH appear to us fully to justify the conclusions of the Lieutenant-Governor as to the

necessity for a sweeping reform of the system. It may also be fairly asked why did Dr. SMITH delay his representation of the "cumbrous and faulty" character of the system in operation until he was about to proceed on leave to England, and then delegate to his *locum tenens* the not over-pleasant duty of showing up the defects of the "approved system"? A considerable portion of Dr. SMITH'S letter is taken up with an examination of details which might with great propriety be brought under the notice of the head of his department, but which do not appear to have much bearing upon the wide general question of hospital administration. A careful perusal of Dr. SMITH'S letter forces upon us the conviction that the Lieutenant-Governor was fully justified in the conclusions at which he arrived, that the medical officers of the hospitals had shown zeal, devotion, and skill in the discharge of their professional duties; but that there was a want of effective administrative supervision which seriously affected the financial condition of these establishments. That the introduction of a better system was required is very manifest; it yet remains to be seen whether that has been attained by the recent changes. We think the Indian Government has acted wisely in publishing Dr. SMITH'S letter, as it removes all appearance of injustice done to that officer, but it may be questioned whether he acted prudently in calling for its publication.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS AND PRELIMINARY EDUCATION.

As we announced last week, the Council of the Royal College of Surgeons has adopted the following motion, by Sir James Paget:—

"That the Council, having assented to the recommendation of the General Medical Council, that 'it is desirable that the Examinations in General Education should be left to the Universities and to such other Bodies engaged in General Education and Examination as may from time to time be approved by this Council, &c.,' and being satisfied that such examinations are now sufficiently numerous and accessible to all persons desirous of studying surgery, and will be duly under the supervision of the General Medical Council, give notice that the Examinations held, with their authority, by the College of Preceptors will cease to be held after September, 1881."

This step will be acceptable to those who believe that the status of the medical profession can be satisfactorily raised only by requiring of those who enter it a better general education than heretofore. As we have more than once had occasion to point out, the preliminary examination hitherto conducted by the College of Preceptors, for, and with the authority of, the Council of the College of Surgeons, has not been in all respects creditable. The subjects for examination in French, German, Latin, and Greek have not been changed for many years. Our readers may perhaps remember that one of the examiners not long ago threw the blame of this upon the Council of the College of Surgeons. A move has at length been made; and when it is remembered that the discontinuance of the preliminary examination will diminish the annual income of the College by £500, the Council must be credited with some degree of public spirit for the step they have resolved to take. It is only proper that they should in return be furnished with some guarantee that the substitute examinations will be of adequate scope and character.

THE PUNISHMENT OF CHILDREN.

No one who has had much to do with children can doubt that punishment is necessary to their proper discipline, or that sometimes it needs to be administered with considerable severity. The sentimental theory that children can be trained and taught "wholly by kindness" generally issues in a practice which is the converse of the principle laid down by Hamlet—"I must be cruel to be kind." There are, however, certain forms of punishment which compare most unfavourably with the old-fashioned birch, and ought to be discouraged, if not interdicted. We have repeatedly pointed out the evils and injuries likely to result from the boxing of ears and the smacking of faces. These "methods" should be summarily repressed by those who are the masters of school-masters and school-mistresses. Cases which have recently occurred have too forcibly illustrated the truth and need of our many warnings. Nevertheless, punishments of this class are still daily inflicted, and until some hard lesson has been taught the pedagogues who resort to this stupid mode of stimulating the dull intellect, there will be consequences of which the few that come to public knowledge are probably a small percentage. The practice of keeping children without their proper food, of locking them up in dark closets, or even of placing them in solitary confinement in light rooms, cannot be defended, because injurious to body or mind. The imposition of tasks is a shortsighted policy, seeing that it makes learning a terror, whereas it ought to be a delight. Can no disciplinarian devise a suitable discipline for youth? Until that discovery is made, it would be better to fall back on the old birch, properly and moderately applied. It made the flesh smart, but it broke no bones; and few, if any, of its so-called victims failed to profit by its occasional administration.

THE TREATMENT OF TYPHOID FEVER.

THE debate on the treatment of typhoid fever, held at St. Thomas's Hospital on the 10th inst., in connexion with the Metropolitan Counties Branch of the British Medical Association, although interesting, did not elicit much that was novel. The president of the Branch, Dr. Habershon, occupied the chair, and the debate was opened by Dr. Bristowe, who dealt with the subject under the heads of food, medicines, alcohol, and baths. A milk diet was urged as of chief importance. Dr. Bristowe doubted if any remedies had direct effect in controlling hæmorrhage. Alcohol was not necessary, except in a few cases, when it should be given for its stimulant effect. As to baths, he doubted their efficacy, and thought that if they were as valuable as statistics showed, their good effects should be obvious whenever they were tried. In two cases he had had he thought fatal pulmonary congestion had been produced by the use of baths. He concluded his remarks by sketching the manner in which he himself would wish to be treated were he the subject of the fever. Dr. Broadbent, who followed, thought the diet should not be wholly restricted to milk, which it was important to give only as a food, and not as a drink to relieve thirst, for diarrhoea was often produced by the undigested curds. Sometimes beef-tea set up diarrhoea. Besides correcting the diet when diarrhoea was present, he would use opium enemata. In cases of hæmorrhage he gives large doses of opium to arrest peristalsis; ergot and turpentine were also useful. Opium was also of great value in the relief of tympanites. He described his attitude towards baths as one of gradually increasing confidence. Dr. Cayley read a letter from Dr. Brand of Stettin, giving some remarkable statistics from the military hospitals of Germany in favour of the bath treatment—a chief element in success being the adoption of the method at the very onset of the disease. This was possible in private practice and in military hospitals, but not in the civil

hospitals, where patients do not seek admission until they are compelled to do so by the advance of the disease. In Germany it had been found possible to carry out the bath treatment in private practice. The treatment was certainly *not* a dangerous one. Dr. Norman Kerr made some remarks, in which he admitted the need of the medicinal use of alcohol in some cases of the disease. Dr. Collie said that out of 100 cases seventy-five would get well with simply good nursing, fifteen would die, and the remaining ten might or might not recover. Such was his experience, and he had abandoned the bath treatment, as not only useless but even dangerous. He could not put faith in continental statistics, and thought that many cases of mistaken diagnosis were included in them. Dr. Ord had certainly seen good effects from the use not of cold but of slightly tepid baths in selected cases of high pyrexia, which he believed had a relative effect as well as a control over the whole morbid process of typhoid fever. Dr. Mahomed spoke in favour of the cold-bath treatment. He also mentioned a case of severe hæmorrhage which he had recently successfully treated by transfusion.

It must be evident that if the cold-bath treatment is to be properly tested it should be applied systematically in every case of the disease, and the earlier the treatment is commenced the more likely is it to control the fever. In this country this treatment is on its trial, and it is important that the trial should be a fair one and carried out in full confidence, and at the same time with the caution which every physician would naturally employ in order that no ill effects may be produced by it. The facts adduced from Germany and France are too strong to allow prejudice to prevent the treatment from being fully introduced here if it be found that these results can be substantiated.

THE THIRD INTERNATIONAL CONGRESS OF HYGIENE.

THE printed summary of the labours of this great gathering of sanitary reformers has reached us after some delay, and we recognise among the speakers and the representatives of the various European nationalities the same names that were familiar to us during the second International Congress, held at the Paris Exhibition in 1878. We may at once state that the fourth Congress will be held at Geneva in September, 1882, and it is confidently anticipated that London will have the honour of entertaining the fifth Congress in 1884. At Turin, as at Paris, the number of English members present was very limited, while, on the other hand, the various continental nationalities were not only numerous represented, but several Governments sent official delegates; and His Majesty King Humbert presided in person at the first sitting of the Congress. Among the various resolutions adopted we note one in favour of a permanent international committee to study and prevent the spread of epidemics; another urging the appointment, in each State, of a Central Health Bureau with a special budget and functionaries independent of political fluctuations. The principle of compulsory vaccination and revaccination in all countries, and the construction of disinfecting ovens in all large centres, together with enforced purification by dry heat of all infected bedding and clothing, were unanimously proclaimed. Among the minor questions, we note a protest against the incomplete consumption of oxide of carbon by gaslights, and a resolution in favour of large type for school books, which at present are too often printed in a manner calculated to strain the eyesight of the children. A lateral light in schoolrooms was considered preferable to a skylight. Short hours of study were recommended, and it was urged that in each important educational establishment elementary principles of hygiene should be taught by a medical professor. The Congress also advocated the construction of barracks in the form of detached pavilions, and urged that soldiers should first join the ranks

in April or October, instead of, as at present, in mid-winter. The examination for naval captains should comprise a far larger knowledge of naval sanitation. The Congress also urged that in publishing statistics relating to lying-in hospitals care should be taken to give the average duration of the sojourn of the patients in the establishments, otherwise it would be impossible to estimate their respective degree of salubrity. Such, in a few words, were the principal points discussed and opinions adopted by this concourse of sanitary reformers. The proposal to meet again at Geneva was hailed with enthusiasm, for most persons are glad of an excuse to visit Switzerland; and sanitary matters are understood better by the twenty-two legislative bodies of this small Federal Republic than by some among the neighbouring powerful and centralised kingdoms.

PIGMENT IN GIANT CELLS.

THE giant cells of pulmonary tubercle have been the subject of many observations during the past few years, but M. Cornil believes that he is the first to call attention to the frequency with which they contain pigment. Various stages in the pigmentation may be observed. In some cells, which possess a marginal zone of nuclei, and which have been treated by picrocarminate of ammonia, the nuclei are well coloured, while the protoplasm remains of an orange-yellow. In the middle of this protoplasm and around the nuclei are a few black granules. In other giant cells these black granules are more numerous, and occur within the nuclei as well as in the protoplasm of the cell. When the degree of infiltration is still greater, the giant cells do not show a single nuclei coloured by carmine, but only a rose-coloured mass densely infiltrated with fine granulations which are accumulated at points probably representing the previous nuclei. Although thus altered, the giant cells have preserved their form, size, and usual prolongations, but the tubercle has commonly become altogether fibrous, and presents interlacing connective and elastic fibres, which form concentric zones around the giant cells. Among these fibres there are flattened connective-tissue elements, or small round corpuscles, which are also often pigmented. These masses of fibrous tissue are, in turn, enclosed in lung tissue, which is in a state of interstitial pneumonia, with septa thickened, and alveoli containing round cells filled with pigment. M. Cornil points out that the giant cells in fibrous tubercle seem to have undergone degenerative induration, and that the carbonaceous particles, from whatever source they come, once deposited in these elements, remain there indefinitely, and, indeed, help to preserve rather than to destroy the cells.

TRINITY COLLEGE, DUBLIN.

LAST week Sir Edward B. Sinclair, King's Professor of Midwifery in Trinity College Medical School, delivered an inaugural address. After referring to the past of obstetric medicine, and to the high position which it at present occupied, he mentioned that the chair of Midwifery, which was established in 1869, and to which he was then appointed, was placed in connexion with Sir Patrick Dun's Hospital. Afterwards the maternity now connected with that hospital was established, though not without great difficulty, and was now a flourishing institution. As he had been an army medical officer, the requirements of the wives of soldiers presented themselves to his view, and it occurred to him and the lady superintendent of Sir P. Dun's Hospital that it would be an excellent thing if they could make midwives of the soldiers' wives. This project was brought under the notice of the Duke of Cambridge, received the approval of the military authorities, and had since been carried out. The plan adopted was to give gratuitous instruction to a selected number of the wives of soldiers, and since 1869 he had sent to the British army no less than 400 midwives,

who had been trained in Sir P. Dun's Hospital. Sir E. Sinclair said that it had become apparent that there ought to be an extension of the practice for the purpose of providing the soldier "on service" with a well-trained hospital nurse, for, as they all knew, that was not a function which could be performed by the midwife. General nurses who attended cases of zymotic diseases and erysipelas could not approach the bedside of the woman in confinement. This idea had lately been taken up by Viscountess Strangford, who expended her time, fortune, and health in works of practical charity. She had pointed out the expediency and practicability of training the wife of the soldier as his hospital nurse, and she was at present endeavouring to establish a teaching system for this purpose in London.

EDWIN BOOTH AS HAMLET.

ALTHOUGH matters theatrical lie outside the domain of THE LANCET, we have always made it a custom to direct the attention of our readers to every fresh exponent of Shakspeare's greatest character, because we feel that the study of this puzzling psychological fiction has perhaps more genuine interest for members of the medical profession than for any other class of persons.

Edwin Booth gives, we believe, a correct view of the Prince's mental condition. Of a sensitive and affectionate organisation, he is profoundly affected, both mentally and physically, by his interview with the Ghost; and Mr. Booth succeeded in producing the impression, without any strain or effort, that this trying ordeal left an effect upon the nature of Hamlet so that, to use a common expression, he was never quite the same man afterwards. His interview with Horatio and Marcellus after the disappearance of the Ghost was a really fine rendering of a most difficult part of the play, and from the time of the Ghost's exit to the fall of the act drop it was evident that the mental shock had been terribly severe—that it was an effort to him to collect his thoughts, and that while conversing with his friends his mind was often far away.

For the rest, we must say that Mr. Booth's representation, although it was not marked by any very original or striking points, was, from a merely technical point of view, one of the best pieces of stage-performance we ever saw. The minutest syllable that Mr. Booth uttered, even in his most subdued tones, was, we believe, plainly audible in the far corners of the pit and gallery. To hear a fine voice, used with consummate skill, giving utterance to Shakspeare's masterpiece, is in itself a great treat—a treat which many popular Shakspearian actors quite fail to give us. Again, Mr. Booth's command of what is known as "stage business" we have never seen excelled. His actions were rapid, suitable, free from all exaggeration, and, if we may be allowed the expression, exquisitely neat. The use which he makes of a pair of delicately-chiselled, nervous hands is such as any actor might envy. To give an example, his attitudes and manner while questioning his friends, in the first act, as to the circumstances of the Ghost's appearance to them, were at once masterly and easy. Mr. Booth has an expressive face and a fine figure, and his pronunciation is quite free from Americanism.

FRACTURE OF THE SACRUM.

By its position and structure the sacrum is peculiarly free from liability to fracture except from bullet wounds, and, although it is sometimes found fissured, or even comminuted in severe crushes of the pelvis, simple uncomplicated fracture of this bone is a very rare accident. Erichsen has seen one such case, the injury being a blow from the buffer of a railway carriage, and proving rapidly fatal. Agnew says that simple transverse fracture of the sacrum is usually accompanied by fatal injuries to the pelvic viscera. A remarkable

case has recently been put on record in Paris. A woman, thirty-six years of age, was brought into the St. Lazare Hospital with the history of having fallen about eight feet on to her buttocks. She fainted, and when she was conscious was quite unable to sit. A slight transverse depression corresponding to the middle of the sacrum was readily felt from the back, the part was very tender, and pressure gave fine crepitus; extensive ecchymosis quickly occurred over the whole sacrum. From either the rectum or vagina the line of fracture was readily felt, and the projection forwards of the lower half of the sacrum verified, this part of the bone was easily moved with crepitus. Reduction was easily effected by the finger pressed back from the front, and displacement did not recur. A bandage was applied firmly round the pelvis and the patient kept in bed. Defecation gave intense pain, and the woman was unable to lie on her back for a fortnight, but sat up in bed on the twenty-eighth day, and got up in the ward on the forty-second day. There were no signs of pressure upon or other injury of the lower sacral or coccygeal nerves. In cases where there has been a tendency for the displacement to recur various mechanisms in the rectum have been employed to keep the bone in position, such as a plug of wood, a stuffed silver cannula which could be opened to allow the passage of fæces. The ease with which in the above case the reduction was effected shows that the displacement was due to the direction of the fracturing force, and not to the action of the muscles attached to the lower fragment. The main difficulty in the treatment of these cases where the fracture is the sole injury is the intense pain in defecation, and the local disturbance it induces. Some have, by means of opium, kept the bowels confined and then cleared the rectum by an enema every week or ten days. It is still better to diet the patient very carefully with a view to the production of the smallest possible quantity of fæces, which may then be easily and almost painlessly removed by means of an enema every three or four days.

CONSIDERATENESS IN PATIENTS.

A WRITER on club practice in the *Western Daily Mercury*, to whose former letter we have already referred, communicates a second letter on the same subject, urging the advantage of mutual considerateness on the part of doctor and patient in all club arrangements as tending wonderfully to harmonious and pleasant working. This same quality of considerateness is very valuable, too, in private patients; and, strange to say, there is the greatest possible difference in patients with respect to it. Some patients almost never send at inconvenient hours, nor disturb the arrangements of the day by rash messages. Other patients, again, are attacked with illness just after their medical man has returned from his visit to their end of the town, and send off post haste demanding his immediate attention to an ailment which existed yesterday, and will keep quite well till to-morrow. The former patients have great advantages. The practitioner soon finds out the value of messages. He knows that when the considerate patient sends a message out of time it means urgency, and he acts accordingly.

TENDON-REFLEX.

AN important paper is contributed to *Brain* (Part X.) by Dr. Augustus Waller, "On Muscular Spasms known as Tendon-Reflex." His suggestion is that the now well-known phenomenon, "patellar tendon-reflex," is not a spinal reflex, but merely a peripheral reaction of muscle, and that it is only a test of spinal conditions in the sense that other peripheral reactions of muscles (electrical or mechanical) are tests of spinal conditions. The experimental data of the paper are furnished by measurements of the interval between percussion of the tendon and contraction of

the muscle. These are to the effect that on the normal human subject the above interval does not sensibly differ from the latency of the muscle to electrical excitation of its substance, or of its motor nerve; and that all these intervals, likewise the interval between percussion of the substance of a muscle and its contraction, and that also between percussion of a motor nerve and contraction of a supplied muscle, do not differ more than can be accounted for by differences in the intensity of stimulation, the normal interval or latency of all these phenomena being from $\frac{1}{100}$ to $\frac{1}{50}$ of a second. The paper is concerned only with the physiological interpretation of tendon-reflex as a direct "neuro-muscular" effect of the mechanical stimulus; it does not attack the clinical significance of the test.

THE PREVENTION OF FOGS.

Dr. C. W. SIEMENS has communicated to *Nature* of Nov. 11th a plan for remedying the growing evil of London fogs. The essence of the scheme is a reduction of the amount of coal consumed for domestic and other purposes. Dr. Siemens advocates the substitution of a special gas-grate for the ordinary coal-fire. Two sketches illustrate the article and show at once the simplicity and efficiency of the plan. The two chief drawbacks to the gas-grates in common use are the expense and the obnoxious fumes that are given off. Both these Dr. Siemens professes to have got rid of, and he claims for his plan an economy of heat, fuel, and money. The bottom of the new grate consists of a solid iron plate instead of bars, and this plate is rivetted to a stout copper plate facing the back of the grate. In front, between the iron plate and the lowest bar of the grate is an interval of about an inch, into which is fixed a half-inch gas-pipe perforated with holes of about one-twentieth of an inch in diameter, placed zigzag at distances of three-quarters of an inch along the upper surface. When in use the cavity of the grate is filled with coke, which is heated by the jets of the gas-flame. From some comparative experiments Dr. Siemens concludes that the coke-gas fire is not only warmer and cheaper than an ordinary fire, but is smokeless. "I hold," he states, "that it is almost barbarism to use raw coal for any purpose, and that the time will come when all our fuel will be separated into its two constituents before reaching our factories or our domestic hearths. Such a measure would not only furnish us with a complete solution of the smoke question, but would be of great value also as a money saving." Dr. Siemens generously adds, that he has taken up this question without any idea of profit, and shall be happy to furnish builders and others desirous to introduce the coke-gas grate with the necessary indications to ensure success.

CHIAN TURPENTINE IN CANCER.

A RATHER remarkable improvement in a case of recurrent scirrhus of the breast subjected to treatment by Chian turpentine has just been recorded in Paris, in a letter addressed to the *Tribune Médicale* by Dr. Sabah of Eauze. In June, 1878, M. Lannelongue of Bordeaux removed a mammary tumour, the clinical and microscopical characters of which were those of scirrhus cancer. In April, 1880, Mme. D— again consulted M. Lannelongue, who, however, decided against another operation, owing to the degree with which the axillary glands and chest-wall were invaded by a recurrence of the growth. Treatment by Chian turpentine was commenced on October 13th, when the right breast was double the size of the left, and was traversed by enlarged vessels, the axillary glands completely involved, the arm swollen, and the hand paralysed, and lumbar pain so severe and continuous as to require injections of atropine and morphia three times a day. The general health, however, was not affected. The drug was given hourly, and for the

first two days produced diarrhoea; but on the third day the pain began to subside, and the arm to diminish in size. On the ninth day the menses, which had been suppressed for more than five years (the patient was forty-two years old), returned, and lasted five days, during which the turpentine was withheld. The treatment was then resumed, and by October 30th the circumference of the arm had been diminished by $\frac{3}{4}$ centimetres, and the tumour appeared to be resolving. Dr. Sabah looked upon the return of the catamenia as at once a proof and a guarantee that a cure was being effected. It must, however, be conceded that a sufficient time has not elapsed to speak of this as a case of cure, and it is to be hoped that the history of the case will be further reported at some future date. On many grounds too early publication of such facts is to be deprecated rather than encouraged.

THE MORGUE.

THE demonstrations at the Morgue by M. Brouardel were resumed on November 5th, in the presence of a large auditory of students and practitioners of medicine. In his opening remarks M. Brouardel reminded his hearers of the necessity of keeping secret the revelations made within the building, in order that justice might not be defeated. He pointed out that publicity under these restrictions was a help and safeguard to the expert; and in a few words expounded the method he intends to follow at these meetings. The lectures will take place on Wednesdays and Fridays, at two o'clock; and after reading the commission given him by the Public Prosecutor, he will proceed to the official autopsy. Notes will be taken by the pupils, which will be read at the following meeting. In his opening lecture he discussed, with the aid of experiments, the signs of hanging and infanticide.

HOSPITAL SUNDAY IN DUBLIN.

COLLECTIONS in aid of the Dublin Hospital Sunday Fund were made last Sunday in most of the churches in that city, and although considerable depression exists throughout the country, yet it is hoped that when the total amount is announced it will not be under what was obtained last year. Since the establishment of the institution in 1874, the sums realised for so deserving a purpose have yearly increased, being £3306 in 1874, and £4344 in 1879. Each charity which participates in the funds collected is assisted (1) according to the amount of voluntary contributions received by it, and (2) by the amount of work done.

THE office of Assistant-Librarian to the Royal College of Surgeons in Ireland, vacant by the resignation of Dr. Spencer, will be filled up this week. Although the emoluments of the post are only £100 per annum, yet no fewer than thirty-five applications were received for the appointment. The Council, however, at a recent meeting selected seven of the candidates, and their claims were to be considered on the 18th inst. The person appointed is expected to devote his entire time to the duties of the office.

HENRY PERCY POTTER, F.R.C.S., of St. Thomas's Hospital, has been awarded the Howard medal for 1880 of the Statistical Society, with the sum of £20, for competitive essay "On the Oriental Plague in its Social, Political, Economical, and International Aspects, more especially as regards the labours of John Howard."

THE death is announced of Dr. Edward Seguin of New York. The deceased physician was a voluminous writer, and occupied at his death offices of distinction in connexion with medicine. He was born in 1812, and died on the 28th ult. at his residence in West Twentieth-street, New York.

THE Queen has been pleased to give orders for the appointment of Inspector-General of Hospitals and Fleets William Macleod, M.D., to be an Ordinary Member of the Civil Division of the Third Class, or a Companion of the most honourable Order of the Bath.

THE Academic Council have nominated Dr. Banks to the Regius Professorship of Physic in the University of Dublin, recently held by Dr. Hudson; and Mr. E. H. Bennett to the Professorship of Surgery. These nominations by the Council are tantamount to election.

THE fire which recently destroyed three-fourths of the town of Niigata, Japan, included in its ravages, we regret to hear, the dispensary and hospital in which Dr. Palm has been doing useful work in connexion with the Edinburgh Medical Missionary Society.

AN attempt to dethrone Greek at Cambridge University has proved unsuccessful, a proposition at a late Congregation to substitute a knowledge of French or German for the compulsory study of the classic language having been rejected.

WE understand that Mr. Joseph Lister, F.R.S., has been nominated by the Council of the Clinical Society for the office of President; and that Dr. S. Wilks has been similarly nominated by the Council of the Pathological Society.

WE understand that fresh contributions have been received by Professor Cobbold from Dr. Manson, specially relating to the immigration and emigration of *Filaria*, and their supposed connexion with the febrile state.

THOMAS EVELYN LITTLE, M.D., University Anatomist, has been elected President of the Biological Association, Trinity College, Dublin, for the ensuing session.

DR. F. F. MAITLAND MOIR and Dr. J. G. HALL are stated to be candidates for the vacant surgeoncy of the Aberdeen Royal Infirmary.

MR. REGINALD HARRISON, F.R.C.S., has been appointed one of the Examiners in Surgery at the University of Durham.

M. DUPLAY has been nominated by the Faculty of Medicine of Paris to the Professorship of External Pathology.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kensington.—Dr. Orme Dudfield's report for the four weeks ending Oct. 9th, in addition to the vital statistics of the locality for the period, contains several matters of general interest. Writing of the "inveterate" tendency to concealment of cases of infectious disease, he remarks on the contracted interpretation given by magistrates to the words "without proper lodging or accommodation," Sec. 124 of the Public Health Act. They read them with reference to the wants of the sufferer, rather than with reference to the safety of the remaining inmates of the same house, the sub-heading of the Act, "Provision against infection," apparently being held as of no significance in guiding as to the interpretation of the sections under that heading. Dr. Dudfield gives also a curious illustration of the difficulties which occasionally arise in the removal of non-pauper sick. We

are glad to learn from this report that a sub-committee was about to proceed to Leeds with a view of inspecting the process in use by the sanitary authority there for destroying refuse matters by heat, and that the question of a periodical removal of refuse from premises is likely to be considered. If Kensington, Paddington, and St. Pancras should adopt rational principles of refuse removal and disposal, we may reasonably hope that the example will spread generally throughout the metropolis.

INFECTED MILK: DIPHTHERIA.

An important case was recently heard before the Kingston County Bench of Magistrates under the Dairies and Cowsheds Order. Dr. Owen Coleman, the medical officer of health, stated in evidence that seven cases of diphtheria had occurred in his practice, and from inquiries made with a view of tracing the disease he heard of other cases, and found that all the families were supplied with milk from the same source. Acting upon this information, in company with Dr. W. Price Jones, the inspector under the Dairies and Cowsheds Order, he visited the premises from which the milk was obtained, and found there a child dying from malignant diphtheria. No complaint had to be made of the general condition of the premises, but there was reason to believe that the case of diphtheria he saw was not the first and the only one which had occurred there. No special precautions had been taken to prevent contamination of the milk, and no information had been communicated to him of the existence of the disease. The magistrates held the case proved, and inflicted a fine.

The case presented several curious features in its course, which require a brief notice from us. It appears that neither before nor after examining the case of diphtheria did Dr. Coleman and Dr. Jones communicate with Dr. Robert Collum, the medical gentleman in attendance upon the case, and of this Dr. Collum complained in the witness-box. Moreover, Dr. Coleman and Dr. Jones are represented as "rigorously cross-examining" Dr. Collum in the witness-box. No explanation is given of the circumstances under which the ordinary rule of professional courtesy was set aside in this instance, or as to medical men assuming the anomalous position of cross-examiners of a brother practitioner in a court of justice. A statement of Dr. Collum's in the course of his evidence, that he was unaware of the regulations made for the government of dairies is noteworthy. Has the Surbiton Sanitary Authority been sufficiently careful to make the medical practitioners in its district aware of the relations they would have with them in reference to infectious diseases?

INSANITARY SUBURBAN LONDON.—WILLESDEN.

The Sanitary Authority of Willesden, the Local Board, has been seriously discomposured by the action of one of the inspectors of the Local Government Board. Willesden has an unsavoury reputation, and its Local Board has for some time appeared to think it a point of honour to maintain this reputation. Lately, however (and not before it was needed), a Ratepayers' Association has been formed, and, in the interest of the ratepayers, appears to be looking after the operations of the Board, very much to the disgust of the latter. This Association has recently sprung a mine upon the Local Board which bids fair to bring sanitary matters to a crisis in the place. The Board, not unmindful of its own convenience if careless about the comfort and health of the ratepayers whom it presumably represents, asked the Local Government Board for permission to borrow money to purchase a site for offices and a store-yard. Whereupon Mr. Thornhill Harrison, C.E., was directed to make inquiry on the spot as to the circumstances under which the loan was needed. This gave occasion for a deputation of the Ratepayers' Association to appear before the inspector, and state their grievances as to drainage. The Board, not anticipating anything besides a formal inquiry, were taken wholly by surprise, and protested against the intrusion of any subject into the inquiry other than the question of site for offices and store-yards, when they found to their dismay that Mr. Harrison was empowered to make inquiry as to the doings of the Board with respect to previous correspondences with, and projects submitted to, the Local Government Board, and which in some way appeared to be at a standstill. The end was, that Mr. Harrison, as reported in the local press, expressed the opinion that the Local Board had "grossly neglected its duty in the sewerage matter," and

he gave the Board to understand that unless the Board quickly mended their ways it would presently, in all probability, be called upon to experience the somewhat awkward pains and penalties provided by law for the control of recalcitrant local authorities. In other words, the Local Board had asked for a loan to promote the comforts of the members and its officers, and found itself landed within a very measurable distance of a writ of mandamus.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

An influential deputation, which included the Presidents of the Colleges of Surgeons and Physicians in Ireland, waited on the Lord Mayor of Dublin on Wednesday last, the 17th inst., for the purpose of obtaining the co-operation of the Corporation of Dublin in reference to the introduction of a Bill in Parliament by the city members, for the compulsory notification of infectious diseases in Dublin. Dr. MacDonnell, President of the Dublin Branch of the British Medical Association, introduced the subject, and stated that both the Colleges of Physicians and Surgeons approved of the proposed measure, and had passed resolutions in reference to the matter. It was suggested that the notifying of an infectious disease occurring in any household should be carried out by the proprietor or head of the house where the disease existed, and not by the medical attendant, the majority of the deputation believing that if the latter procedure was adopted, it would lead to a breach of confidence on the part of the practitioner. It was also intended that the head of the house in which the disorder existed should receive a printed notification from the physician in attendance to that effect, and should then be compelled, under a penalty, to communicate the same to the sanitary authority. It was pointed out that notification of infectious diseases existed in several parts of England, in Edinburgh, the United States, &c.; and that although objections had been made at its introduction in those places, yet the arrangement had worked satisfactorily. The Lord Mayor promised every assistance in his power, and ultimately proposed that a deputation should wait on the Chief Secretary for Ireland, to induce him to introduce a Bill, or, if not, to promise his support to any private member taking the initiative in the matter. He also thought that the Bill should not be confined to Dublin, but should extend to the whole of Ireland.

THE LOWER THAMES VALLEY SEWERAGE.

It is reported that the Local Government Board has refused to assent to the Molesey scheme for the drainage of the districts placed under the Lower Thames Valley Main Sewerage Board, and which formed the subject of a protracted public inquiry by one of the engineering inspectors of the Board not long ago, and has recommended that a more general scheme, known as the West Kent scheme, suggested by Sir Joseph Bazalgette, should be adopted. This latter scheme, however, was, we understand, reported against by the late Colonel Cox, R.E., then one of the engineering inspectors of the Local Government Board, about five years ago.

The "little bill" for the Lower Thames Valley sewerage inquiry, held not long ago by one of the engineering inspectors of the Local Government Board, is reported to amount to £19,804.

DISSEMINATION OF SCARLET FEVER BY MILK.

Dundee appears to be the scene of a somewhat extended outbreak of scarlet fever, caused by the dissemination of the infection in the milk supplied from two dairies. The disease, it was found, followed the distribution of the milk from the two dairies in question, and scarlet fever was discovered to exist among inmates of both dairies.

A large and important deputation, headed by the Duke of Bedford and Mr. Brand, the Speaker of the House of Commons, waited upon Mr. Dodson, the President of the Local Government Board, on the 12th inst., to urge upon his attention the mischief to property and to the public health caused by the increasing liability to the flooding of our rivers, and the necessity for legislation on the subject, with a view of regulating the course of streams and limiting their overflow. The deputation assumed that the report of the Lords' Committee upon River Conservancy generally supplied a basis upon which legislation might proceed. Mr. Dodson undertook to submit the views of the deputation to

his colleagues in the Government, and assured the members that they would receive the consideration that the gravity of the subject demanded.

The Local Government Board for Ireland have recently had under consideration the observations made in the House of Commons by Mr. Moore, M.P. for Clonmel, as to certain alleged abuses and irregularities in the Belfast Workhouse; and as the Chief Secretary for Ireland undertook that the charges made by Mr. Moore should be thoroughly sifted, a searching inquiry will shortly be instituted as to the general management of the institution by the guardians, and its present condition, having reference specially to the discipline and classification of the inmates. Also as to the state of health and the rate of infant mortality, and the accommodation for the destitute poor, having regard to the recent order of the Local Government Board limiting the number of inmates. The inquiry will be conducted by two inspectors, Mr. Burke and Dr. MacCabe.

A member of the Vestry of Lambeth was on the 12th inst. fined by the police magistrate of that district £5, to which were added costs amounting to £1 11s., for having neglected to comply with the regulations of the Lambeth Water Company in regard to the constant supply of water to certain houses belonging to him. On a first hearing of the case the defendant had promised to carry out the regulations, but yesterday it was shown that he had complied only in part, and had actually cut off the supply of water to the closets of the houses.

Dr. Tatham, the medical officer of health for Salford, observes in his last weekly report: "I cannot too strongly impress upon the teachers of elementary schools the necessity of preventing the attendance at school of children coming from infected homes, and I desire to caution parents against sending their children to school as long as infectious disease exists at home. The proceeding is illegal, and offenders, if discovered, will be severely dealt with by the Corporation."

At the meeting of the Metropolitan Asylums Board on the 13th a complaint made by a local sanitary authority in Hampshire that the box of clothes of a patient who had died in the Homerton Fever Hospital had been sent without disinfection from the hospital to his friends, and thus caused an outbreak of fever in the locality where they lived, proved to be unfounded. The box of clothes in question had at no time been at the hospital.

It is currently reported that public vaccination in Leicester is so seriously in arrear that the parents of not less than 1200 children are liable to be summoned for neglect, this number being added to at the rate of 400 per quarter. The Local Government Board is endeavouring to induce the board of guardians (the local vaccination authority) to take the necessary measures for amending this serious state of things.

It was stated at a recent meeting of the Hawarden petty sessions, in a case in which the Hawarden Sanitary Authority had taken proceedings against an individual for permitting a house to be occupied which was unprovided with a proper supply of water, that the law did not allow the provision of rain-water to be held as a sufficient supply.

An unusual prevalence of enteric fever at Totnes has been brought to the notice of the Local Government Board, and Dr. Parsons, one of the medical inspectors of the Board, has been instructed to investigate the sources of the prevalence, and, generally, the sanitary condition of the town.

The Lancashire and Cheshire Branch of the Association of Municipal and Sanitary Engineers was held at Salford on the 5th inst. The members inspected the concrete sewage-tanks now in course of construction by Mr. Arthur Jacob, the borough engineer.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality has shown scarcely any variation during the past four weeks, although under the influence of unseasonably low temperature it has somewhat exceeded the average for the period. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5112 births and 3279 deaths were

registered last week. The births were 73 below, while the deaths exceeded by 4, the average weekly numbers during 1879. The deaths showed a further slight increase of 21 upon recent weekly numbers, and were equal to an annual rate of 22·8 per 1000, against 22·6 and 22·7 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 17·1 in Bristol, 18·7 in Sheffield, 18·8 in Plymouth, and 19·4 both in Portsmouth and Oldham. The rates in the other towns ranged upwards to 25·3 in Liverpool, 26·1 in Salford, 27·2 in Newcastle-upon-Tyne, 28·0 in Norwich, and 29·1 in Sunderland. During the first six weeks of the current quarter the death-rate in these twenty towns averaged 22·3 per 1000, against 21·3 in the corresponding periods of the four years 1876-9.

The deaths referred to the seven principal zymotic diseases, which had been 473 and 428 in the two preceding weeks, rose again to 474 last week; they included 163 from scarlet fever, 71 from measles, 69 from fever (principally enteric), and 62 from whooping-cough. The annual death-rate from these seven diseases averaged 3·3 per 1000 in the twenty towns, and ranged from 1·4 both in Plymouth and Wolverhampton, to 7·3 and 8·9 in Salford and Sunderland. The fatal cases of scarlet fever, which had been 167 and 150 in the two previous weeks, rose again to 160 last week, and showed the largest proportional fatality in Sunderland, Norwich, and Brighton. The greatest fatality from measles occurred in Salford and Newcastle-upon-Tyne. The highest death-rates from enteric fever were returned in Norwich, Salford, Leicester, and Nottingham. Diphtheria caused 16 deaths in London, 4 in Liverpool, 3 in Portsmouth, and 2 in Birmingham. The fatal cases of small-pox in London, which had been 2 and 7 in the two previous weeks, further rose to 17 last week, and exceeded any weekly number since the end of April last. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 77, 105, and 114 at the end of the three preceding weeks, further rose to 118 on Saturday last; the number of new cases of small-pox admitted to these hospitals during the week was 31, against 38 and 24 in the two previous weeks. The Highgate Small-pox Hospital contained 9 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 355 in the nine preceding weeks, further rose to 421 last week, and exceeded the corrected average number in the corresponding week of the last ten years by 9; 271 resulted from bronchitis and 99 from pneumonia. The annual death-rate from lung diseases was equal to 6·0 per 1000 in London, and to 6·7 in Liverpool.

In the twenty towns last week 79 deaths were registered without the production of a medical certificate or the holding of an inquest; these were equal to 2·4 per cent. of the total deaths. The proportion of uncertified causes of death did not exceed 1·1 per cent. in London, while it averaged 3·7 per cent. in the nineteen provincial towns. The largest proportion of uncertified deaths occurred in Bradford, Sunderland, Brighton, and Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week was equal to 23·8 per 1000, against 24·2 in each of the two preceding weeks, and was one per 1000 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 19·5 and 20·1 in Dundee and Paisley, to 25·6 and 30·1 in Aberdeen and Greenock. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 149 and 115 in the two previous weeks, rose again to 125 last week; they included 53 from scarlet fever, 20 from diarrhoea, 15 from measles, 15 from whooping-cough, 14 from fever, 8 from diphtheria, and not one from small-pox. The annual death-rate from these seven diseases averaged 5·0 per 1000 in the eight towns, and exceeded by 1·7 the average rate from the same diseases in the twenty English towns. In the eight Scotch towns the zymotic death-rate ranged from 0·3 and 3·2 in Dundee and Paisley, to 7·1 and 7·2 in Leith and Edinburgh. The high zymotic death-rate in the two last-mentioned towns was due to the excessive mortality of scarlet fever; the deaths referred to this disease in the eight towns, which had been 52 and 47 in the two preceding weeks, rose again to 53, of which 27 occurred in Edinburgh, 20 in Glasgow, and 5 in Leith. The 15

deaths from measles included 12 in Glasgow, where but 4 and 2 deaths respectively were recorded from this disease in the two preceding weeks. The 15 fatal cases of whooping-cough were 7 more than those returned in the previous week, and included 7 in Glasgow and 3 in Greenock. The deaths referred to fever, principally enteric, which had been 13 and 20 in the two preceding weeks, declined again to 14 last week; 9 occurred in Glasgow and 3 in Aberdeen. The fatal cases of diphtheria, which had been 28 and 15 in the two previous weeks, further declined last week to 8, of which 7 were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 120, 121, and 127 in the three preceding weeks, further rose to 154 last week; the annual death-rate from these diseases last week was equal to 6·2 per 1000 in the eight Scotch towns, against 5·4 in London.

HEALTH OF DUBLIN.

The death-rate in Dublin showed a considerable increase last week upon the high rates that have recently prevailed. The annual rate of mortality from all causes in the city, which had been equal to 34·8 and 34·4 per 1000 in the two preceding weeks, rose last week to 39·6, a higher rate than has prevailed in any week since the middle of April last. During the past six weeks of the current quarter the death-rate in the city has averaged 34·6 per 1000, against 21·4 in London, and 22·4 in Edinburgh. The 239 deaths in Dublin last week exceeded those in the previous week by 32, and included 28, or 12 per cent., which were referred to the seven principal zymotic diseases, showing a decline of 8 from the number returned in each of the three preceding weeks; 7 resulted from fever (including typhus, enteric, and simple), 7 from whooping-cough, 6 from scarlet fever, 6 from diarrhoea, one from small-pox, one from measles, and not one from diphtheria. The annual death-rate from these zymotic diseases was equal to 4·6 per 1000 in Dublin last week against 3·2 in London, and 7·2 in Edinburgh. The deaths referred to fever and scarlet fever showed a decline of 2 and 7 respectively from the numbers in the previous week, whereas the fatal cases of whooping-cough were rather more numerous. The death-rate from fever in the city during the past six weeks has considerably exceeded that which prevailed in the preceding three months. Infant mortality showed a further increase last week, and the deaths of persons over sixty years exceeded the number in the previous week by 10.

PRESTON MORTALITY STATISTICS.

Preston is one of those towns which are mainly responsible for the unfavourable position in the sanitary scale which Lancashire takes among the English counties. Preston is included among the fifty large town districts for which the Registrar-General in his quarterly and annual reports publishes certain mortality statistics. It appears from these reports of the Registrar-General that during the eight years 1872-9 the annual death-rate in Preston ranged from 27·9 in 1872 to 36·1 in 1874, while the average annual rate in the eight years was no less than 31·0 per 1000. The annual rate of mortality from the seven principal zymotic diseases during the same period also showed a marked excess, and averaged 6·2 per 1000. The excess of infant mortality affords further evidence of the unsatisfactory condition of the town. The Registrar-General's annual summaries show that the proportion of deaths under one year to births was equal to 214 and 225 per 1000 in Preston in 1877 and 1878; and that even in 1879, when the cold wet summer caused an unusually small fatality of diarrhoea, the proportion of infant mortality was so high as 194 per 1000. These figures sufficiently prove that the recent high death-rate in Preston, to which the medical officer of health has called the attention of the Local Sanitary Authority, is no unusual event. It is true that the fatality of diarrhoea showed a marked excess in Preston during July, August, and September, and so raised the death-rate above its normal condition. The annual death-rate from all causes in Preston averaged 25·1 per 1000 in July and 37·8 in August; it appears too, from a report recently presented by the medical officer of health to the Sanitary Authority, that the death-rate during September was equal to 36·3 per 1000. This was almost entirely due to the exceptional fatality of diarrhoea, to which 50 deaths were referred in July, 98 in August, and 129 in September. The deaths referred to other zymotic dis-

eases, if we except the fatal prevalence of measles during the spring, have not till recently shown a large excess; but the high death-rate from zymotic diseases prevailing in recent years has been maintained, and the rate of infant mortality during the first nine months of the year averaged 239 per 1000 births. It may be hoped that this long-continued excess in the rate of mortality in Preston, which has recently attracted considerable attention, will impress upon the Town Council the urgent necessity for vigorous sanitary action, under the advice of their medical officer of health.

Since the above was in type we learn from the medical officer of health's report for October that a fatal epidemic of typhoid fever prevailed during that month.

VITAL STATISTICS IN ALGERIA.

Dr. René Ricoux of Philippeville has recently published some interesting statistical studies on the colony of Algeria. The increased facilities of communication will render this portion of the Mediterranean coast more and more accessible to invalids, and there are already a good number of English patients who spend the winter in Algeria. Unfortunately here, as elsewhere in the south, the sanitary condition of the towns is so neglected that the good effects of the climate are counteracted by the bad drainage, &c. Nevertheless, the number of persons who attain remarkably old age in Algeria is more considerable than in France, Italy, Austria, Belgium, and even Sweden. Thus we find that among the deaths registered at Algiers from 1864 to 1877 there were 1390 persons who died at ages varying from 80 to 118 (as asserted) years. This figure is subdivided in the following manner:—845 persons died between their 80th and 90th year; 283 from 90 to 100. As many as 88 persons lived to be 100 years old; 9 died at 103 years; 15 at 104; 8 at 110; 4 at 115; and 2 at 117 and 118 years of age. The remaining 36 centenarians died at an undefined period between the ages mentioned. Of these 1390 aged individuals 530 were men and 859 women, showing that in Algeria, as elsewhere, it is the women who live the longest. The proportion of persons who in Algeria die between 80 and 90 years is as 60 to 1000 deaths; from the years of 90 to 100 the proportion is as 26 per 1000; and 9 persons in 1000 are centenarians.

More important than these statistics of old age is the general death-rate, and this, according to Dr. Ricoux's calculations, shows a marked improvement. The mortality among the French colonists from 1853 to 1856 reached the very high figure of 46·3 per 1000; but in 1872 this death-rate had fallen to 33 per 1000, and in 1876 it had reached the proportion of 24·7. The augmentation in the number of births during the same period is also very remarkable. The actual increase of the French population in the metropolis of France is equivalent to 3·16 per 1000 per annum, whereas among the French in Algeria the proportion is set down at 8·89 per 1000.

SCARLET FEVER IN SUNDERLAND.

During last week no less than sixteen more fatal cases of scarlet fever were recorded in Sunderland—a higher weekly number than has been previously recorded this year. The deaths from this disease within the borough, which had been 72 and 41 in the first two quarters of the year, rose again to 65 in the three months ending September last, and in the past six weeks of the current quarter no less than 64 more cases have been recorded. During the ten years 1870-79 the annual death-rate from scarlet fever in Sunderland averaged 1·19 per thousand of the estimated population, and considerably exceeded the average rate in most other large towns. Among the twenty large English towns dealt with in the Registrar-General's Weekly Return the annual death-rate from scarlet fever during those ten years averaged 0·89 per 1000, and ranged from 0·32 in Plymouth to 1·50 and 1·53 in Sheffield and Oldham. In England and Wales generally, and in most of the large towns, the fatality of scarlet fever in the five years 1875-9 showed a considerable decline from that recorded in the five preceding years, 1870-4. In Sunderland, however, the fatality of scarlet fever in the last five years has considerably exceeded that which prevailed in the preceding quinquenniad; the annual rate, which did not exceed 1·02 in the five years 1870-4, rose to 1·79 in the following five years, 1875-9. The disease in Sunderland showed constant and increasing fatality during the four years 1876-9, and the recorded fatality in the first 45 weeks of this year has shown a still higher death-rate.

This fatal prevalence of scarlet fever in Sunderland during nearly five years deserves the earnest attention of the Town Council and their medical officer of health. It would be interesting to know to what extent the hospital accommodation of the sanitary authority has been turned to account for isolating scarlet fever patients during the long epidemic.

PUERPERAL MORTALITY IN PARIS.

The long-continued epidemic prevalence of small-pox and enteric fever in Paris affords the strongest evidence of the unsatisfactory sanitary condition of that city, which is corroborated by a variety of indications in the carefully compiled mortality statistics issued under the superintendence of Dr. Bertillon. It appears that during the first nine months of this year no less than 315 deaths were referred to puerperal diseases, including 2 under the age of fifteen, 247 between the ages of fifteen and thirty-five, and 66 over the age of thirty-five years. These deaths were equal to 7·3 per 1000 of the births registered, whereas in England and Wales the proportion of deaths from puerperal causes to births averages about 5 per 1000. In London, indeed, during the corresponding nine months the recorded deaths due to childbirth did not exceed the proportion of 3·8 per 1000. Thus Paris mortality from these causes has been nearly twice as fatal as that in London. We know that the registered causes of death in England understate the actual puerperal mortality, but it is unlikely that these causes of death are more correctly returned in Paris, and the marked excess of puerperal mortality in that city must be due to other causes.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DIPHTHERIA IN RUSSIA.

A medical conference was held in Poltava on the 22nd ult., with a view to consider what further measures could be taken to arrest the progress of diphtheria in the government. The medical men throughout the province were invited, and there were present delegates from Kharkow (including Professor Jacobi), Catherinoslaw, and Kherson, and Dr. Hubner from St. Petersburg also attended. The conference was opened by an address from M. Joukow, the Vice-governor of the province, and afterwards M. Pétrow, a member of the zemstvo, submitted the following questions for the consideration of the conference. What are the means best for adoption in order to place in force the measures recommended against diphtheria? What have we learned from experience as to the most efficacious method of medical treatment? What are the most practical means of disinfection? Is it not possible to adopt more energetic measures for arresting the spread of the disease in the localities where it now prevails? Is there evidence to show that the disease has appeared in any place where it has not been imported? What data exist concerning the progress and mode of propagation of diphtheria? What is the mean duration of the disease? What is the best mode of proceeding in order to collect precise data regarding the progress of this epidemic? Is the assembling together of the medical men necessary for the collection of these data? What can the zemstvo do to assist in arresting the progress of the disease?

The conference lasted three days, but within that period it had been found possible to consider two subjects only—namely, the distribution of the malady in the different districts of the province, and the means of disinfecting dwellings. As to distribution, it was found that the central districts had suffered most from the disease; and with regard to disinfection an irreconcilable difference of opinion was manifested, which separated the conference into two opposing parties. On the one side it was held that disinfection was a necessary measure of protection; on the other it was regarded as futile.

A sanitary detachment, consisting of two physicians, MM. Nikotine and Norbutt, four assistant-surgeons, and eight sisters of charity, has been sent by the medical department of the Imperial Government to the province of Samara to assist in combating diphtheria there.

SANITARY WORK IN AMERICA: ST. LOUIS.

We have of late been subjected to reproof by more than one of our Transatlantic brethren for expressing ourselves as if the principles of sanitary work applicable to England and Europe would apply also to the United States of America.

We pleaded in our excuse that if we had fallen into error we had erred in good company, and instanced Buck's recent book as an example of a whole body of American writers who had been equally led astray. We are reminded of the subject by receiving the Annual Report of the Health Commissioner of the city of St. Louis for the fiscal year 1879-1880, and by observing how the methods and phraseology of sanitary reasoning and practice familiarly in use here are employed also in the great city on the banks of the Mississippi. In what follows, quoted almost at random from Dr. Laedeking's report, we might be quoting from the report of one of our own medical officers of health. Writing of the use made of the mortality statistics of the city for detecting the distribution of the deaths from different diseases therein, Dr. Laedeking observes: "Closer examination revealed that these fatal cases occurred within circumscribed boundaries in the wards in question. It needed but an investigation of the places most affected to reveal the existence of glaring faults. To be more explicit, there were found wells containing impure water, from which the houses in which repeated deaths from the above stated causes had occurred were supplied; there were found privies of faulty construction, permitting a percolation of their contents into cisterns, from which water for drinking was drawn; there was found, in one instance, a badly-trapped sewer pipe that allowed obnoxious vapours to escape into the habitations occupied by numerous persons, old and young," and so forth. The evils being similar, who can doubt that the principles of relief applicable here are applicable there also? Dr. Homan, the chief sanitary officer, gives us, indeed, a very home-like report of his proceedings for the year, and we observe that the municipality of St. Louis has issued an ordinance for regulating the construction of house-drains in the city, which proves that house-drains there are liable to the same evils as here, and that the remedies deemed best for those evils, including the proper ventilation of the drains, are in principle similar to those incorporated in the Model Bye-laws as regards New Buildings, issued by the Local Government Board.

YELLOW FEVER AND DENGUE.

In its monthly review of mortality for September, 1880, the last received number of the *National Board of Health Bulletin*, U.S. (vol. ii. No. 1), observes: "The statement made in the number for August, that no yellow fever had appeared at any of the exposed points on the coast, must now be modified in view of the acceptance by the National Board of Health of the report of Dr. George M. Steinberg, U.S.A., as published in No. 15 of the *Bulletin*. The report declares the fever which has prevailed since August on the Lower Mississippi, but which is now rapidly subsiding, to have been yellow fever of mild type, and causing in most places but a small mortality. No special measures of isolation or quarantine were adopted, but the disease did not spread beyond the district first affected.

"The epidemic of dengue fever in the South, extending from Louisiana to South Carolina, which is fast disappearing, has affected a large number of people, but caused comparatively few deaths."

Scarlet fever is reported to be prevalent at Hill Fields, Coventry. On the recommendation of the Sanitary Committee of the City Council, the largest public elementary school has been closed.

Scarlatina is prevailing in Winchester, principally in the College. All the cases seem to be of a mild type, and no fatality from the disease has as yet been recorded.

THE SERVICES.

As will be seen by an advertisement in our present issue, the next examination of candidates for commissions in the Medical Department of the Army will be held at the London University, Burlington-gardens, on the 14th of February next and two following days.

INDIA OFFICE, Nov. 15th.—The Queen has approved the resignation of the service of Surgeon Arthur Hemsted of the Bengal Army.

MILITIA MEDICAL DEPARTMENT.—Surgeon-Major Temple Chevallier Paley, 2nd West York Militia, resigns.

his commission; also is permitted to retain his rank, and to continue to wear his uniform on his retirement.

ADMIRALTY.—Fleet-Surgeon W. H. Lloyd has been appointed to the *President* (additional), for temporary service.

Correspondence.

"Audi alteram partem."

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—I think my friend Mr. Lucas has not correctly gauged the moral support the profession was ready to accord the Guy's staff, nor fully realised the strong and widespread sympathy felt for its members by the staffs of other hospitals.

In his letter which appeared in THE LANCET of November 13th he asks, "Of the dozen medical schools in London which has moved to our assistance?" But, Sir, neither the medical schools nor the profession generally have had an opportunity of moving to their assistance. Throughout the greater part of this prolonged struggle the Guy's staff were naturally credited with knowing their own case best, and of having calculated the cost of the warfare into which they had entered. Then came the capitulation, and with such precipitancy that outside assistance was no more than a dead letter.

Mr. Lucas further complains, "Of the hundreds of teachers, two only have taken up our cause." But I have good reason to believe that others, like myself, have attempted to lift up their voices, and have not been heard. I feel convinced that Mr. Lucas is under a mistaken impression if he supposes that the profession has had no further thought about the Guy's conflict than to "look on amused;" and I feel assured that there are very many who deplore a struggle that has, amongst other results, led to the self-imposed resignation of the esteemed Senior Physician and Surgeon of the Hospital.

I am, Sir, your obedient servant,

HENRY MORRIS,

Surgeon to the Middlesex Hospital.

Mansfield-street, Portland-place, W., Nov. 15th, 1880.

To the Editor of THE LANCET.

SIR,—The Senior Physician and Senior Surgeon of Guy's have, I see, resigned their appointments, a step which the profession at large have been expecting, and have encouraged them to take. So far as one can understand the question at issue between them and the governors, no other honourable course was open to them, and we wait impatiently—for the time is fully come—to hear that their colleagues have followed their example. Let this be done, and let the *esprit de corps* of the profession rule us to a man, and the governors will be fittingly discomfited. The course to pursue then is plain. The staff of Guy's having resigned, we presume the governors will desire to fill up the vacancies thus caused, and to this end will advertise. Let them advertise and advertise, and let us—we are in honour and loyalty bound to do it—hold aloof from them and their hospital and nursery hobby, until they reinstate our brethren, giving them full control over the nursing department, as common sense dictates; or let Guy's Hospital be closed, and that for all time, as a standing proof and illustration of the folly which is not seldom found in boards and corporations. Only let us be true to each other, and we may read a lesson to the governors of hospitals and other institutions with which we have to do, which I believe is much needed, and which, it is to be hoped, they will not very soon forget.

Your bold defence of the staff of Guy's, in their righteous opposition to the governors, does you credit; it contrasts favourably with the shilly-shally vapouring of some of your contemporaries.

I remain, Sir, yours respectfully,

WILLIAM DALE, M.D. Lond.

King's Lynn, Nov. 16th, 1880.

ANTISEPTIC MIDWIFERY.

To the Editor of THE LANCET.

SIR,—There is, I think, no doubt that a very large proportion of deaths resulting from confinement are due to puerperal fever. To general practitioners the subject is of the greatest practical importance, since cases of midwifery, scarlet fever, erysipelas, and foul wounds, are not unfrequently under their care at the same time. A case of puerperal fever is one of burning anxiety to the attendant, both at the time and for weeks afterwards, as well as of pecuniary loss. The sacrifice of a life under such circumstances is peculiarly distressing, and the subject has for years engaged my attention.

The precautions I now adopt are the following, which, I am happy to say, have thus far proved effectual. After seeing erysipelas, &c., I change my clothes, and always carry with me a collapsable tube, made for me by Messrs. Richardson of Leicester, containing a solution of thymol in firm vaseline. It should be rubbed well on to the hands when quite dry, and will then last a long time, as it is very difficult to wash off, much more so than lard or oil.

These tubes are very portable and convenient, and I believe their habitual use protects both surgeon and patient from possible contagion.

I am, Sir, yours faithfully,

W. PAULSON, L.R.C.P. LOND.

Mount Sorrel, Loughborough, Nov. 1st, 1880.

PARIS.

(From our own Correspondent.)

THE illness of one of the most popular English physicians of Paris, the Hon. Dr. Alan Herbert, who has been suffering from typhoid fever, has caused a considerable amount of uneasiness amongst the English residents here. A London journal (*Truth*) attributes our *confrère's* malady to drinking contaminated Eau de Seltz, and quotes a formidable analysis which was recently presented to the Academy of Sciences by M. Boutney, in support of this theory. On the other hand, the *Dix-neuvième Siècle* of the 14th inst. contains a letter signed by M. Mondoff, president of the syndical chamber of effervescing water manufacturers, protesting against an article which appeared on the subject in that journal, and claiming that the public should suspend judgment until further and more impartial analyses can be made. According to M. Mondoff, the preparation of seltzer water is supervised by medical inspectors appointed by the Comité d'Hygiène et de Salubrité, and for the last fifty years no ill effect has ever been known to follow its use. The Paris hospitals alone consume 150,000 bottles annually, which are ordered to the patients by the highest authorities in the medical profession, and this in itself is not only proof of its innocuity, but also strong evidence in favour of its usefulness. There are, of course, two sides to every question. Considered from a medical point of view, lead-contaminated effervescing waters may be useful in some cases, such as advanced phthisical patients; this may perhaps account for the reputation which Eau de Seltz enjoys in many of the hospitals, where, moreover, the concentrated typhoid atmosphere within is a perfect guarantee against any importation of typhoid from without. But the same thing does not apply to the general public. Lead as an article of food gives unsatisfactory results, and notwithstanding the protective influence which M. Pasteur has shown to reside in long-cultivated and sufficiently oxygenated virus, most of us would prefer to take our typhoid attenuated in the form of Paris smells, rather than drink it in the shape of an effervescing water, which may be shown by analysis to contain an uncomfortable amount of "dry residue."

The most important event of last week was the "strike" of the medical experts of the metropolitan courts of law. The professor of legal medicine having considered that a certain sentence in the procureur-général's opening speech was "injurious" to himself and colleagues, called a meeting of forensic practitioners, which was attended by seventeen leading members of the profession. It was there decided that until the honour of legal medicine had been satisfied by a proper explanation, no new "*expertises*" should be under-

taken, and the decision of the meeting was notified to the keeper of the seals. Fortunately for public business the procureur-général has made an *amende honorable*, which has enabled M. Brouardel and his susceptible associates to return to their duties.

PYRMONT AND OEYNHAUSEN.

(From our Roving Correspondent.)

PYRMONT has been so almost absolutely forgotten by the profession and the public in England that it is perhaps necessary to state that it lies about fifty miles south-west of Hanover, and is one of the most important places in the Principality of Waldeck-Pyrmont, a petty German State which still retains a semi-independence. The situation of Pyrmont is decidedly advantageous. It lies along the northern side of a spacious valley, enclosed by hills rising from 200 to 400 feet above the level of the plain. The valley is triangular in shape, nearly equilateral, each side being between two and three miles in length. The town is therefore well protected to the north by hills, and is itself slightly raised above the level of the beautiful tract of well-timbered pasture land, watered by the river Emmer (a tributary of the Weser), which forms its southern outlook and occupies almost the entire area of the valley. At the southern extremity of the valley, wedged as it were into the very apex of the triangle, is the quaint old fortified village of Lügde, the towers of which peeping out between the clusters of fine trees in the foreground are a very great addition to the landscape. The soil is a light loam which drains easily, and the rapid running off of the rain-water is secured by the natural slope of the ground from north to south. Owing to the protection to the north the heat in summer is (for the latitude) considerable, but, the valley being wide, there is never any tendency to stagnation of the air and to that baking, stifling heat which is so common in narrow, pent-up localities.

Every spring has a history, but few have such a long or such a magnificent history as Pyrmont. It was certainly known to the Romans, and when in 1863 extensive alterations were made in the basins of the springs, there were found, some twelve or sixteen feet below the level of the ground, a great number of Roman ornaments and two coins, one of the time of Domitian and another bearing the name of Marcus Aurelius. That Charlemagne quartered in the neighbourhood of Pyrmont in the year 784 seems also to be well established. The springs are mentioned in the manuscripts of Henricus de Herfordia, a monk who lived in a cloister at Minden, and who died in 1370. In the middle of the sixteenth century (about the year 1556) the reputation of the holy well at Pyrmont was at its zenith, and the sick, lame, and halt made pilgrimages to it from far and near, and took away large quantities of the water to distant places. It is recorded that the reputation of Pyrmont towards the close of the seventeenth century was so great that in 1681 there were no less than thirty-four persons of Royal blood present during the season. The year 1716 is remarkable for the sojourn in Pyrmont of Peter the Great and Leibnitz, as well as of George I. of England. In 1744 and 1746 Frederick the Great came to Pyrmont to recruit his health, and since that time a very great number of Royal and distinguished personages have followed his example. Of late years the number of visitors to Pyrmont has shown a tendency to increase, and in the last decade the total has risen from about 5000 to nearly double that number. Its popularity is no matter for surprise, for it possesses some most attractive features. Its modern prosperity dates from the time when no landscape was considered complete without an avenue and a "prospect." When William of Orange was planting the Long Walk at Windsor, when the Grand Monarque was showing to the world to what an extent Dutch symmetry might be carried in his new palace of Versailles, the good people of Pyrmont were engaged in planting avenues of elm, limes, chestnuts, and beeches in the neighbourhood of their precious chalybeate springs. These avenues have now reached a grand maturity, and such an array of stately trees is, probably, scarcely to be found anywhere unless it be in Windsor Forest. The chief chalybeate spring, the Stahl-Quelle, forms

the very centre of the town; around it, in the Brunnen Platz, are grouped the chief hotels and lodging houses, and two stately avenues radiate from it. One of these, the Grand Allee, is composed of four rows of trees, and is nearly a quarter of a mile long, with a slight slope from its northern to its southern extremity, where a pretty fountain sends up a never-ceasing spray to glisten in the sunlight, and where a glimpse is got of the green open pastures, which form a dazzling contrast to the somewhat subdued tints of the umbrageous avenue. The Grand Allee is the chief promenade. Here the band plays, and here takes place that morning and evening parade of female costume, which is an essential feature of every bath, and the sole attraction to many of the visitors. This avenue is flanked on either side by the kursaal, reading-room (containing the previous day's *Times*), theatre, caffee-haus (where formerly were the gaming tables), and the inevitable booths, where it is almost impossible to buy anything which is really needful to anybody. Another charm of Pyrmont will be found in its slightly old-world appearance. The houses are of a style which takes one unconsciously back to the time of cocked hats and pig-tails, and the spick and span new nineteenth-century house is only to be seen on the road to the railway station. The performances at the Schauspiel Haus begin at 6.30, and end at 8, so that it is quite possible to go to the play overnight and to be "on parade" at 6.30 in the morning. Every house in the place has its verandah and its balcony, and it would almost seem as if the rooms themselves are never in actual use, one main object in coming to Pyrmont being to live in the open air. Of one hotel (*Hôtel des Bains*) I can speak from actual knowledge in terms of high commendation, for it has large, airy rooms, and a most excellent cook; and it is right to state that many other hotels have a good reputation. It is one of the advantages of Pyrmont that it is not very close to any big cities. Hanover, which, after all, is but a provincial town, is two hours distant, and Pyrmont is thus not used as a recreation ground by persons who come for the day, and who often prove a great annoyance to the residential visitors. The woods round Pyrmont afford a number of splendid walks, and the views from the summits of some of them well repay the slight trouble of the ascent. There are two natural curiosities within a short distance of the town, which give to the mind's eye a glimpse, as it were, of its subterranean conditions. One is the Erdfalle, two funnel-shaped pits, containing deep water, which are said to have been caused by a collapse of the ground—in one instance so sudden as to have engulfed a countryman who was engaged in ploughing. This accident is said to have occurred in the middle of the seventeenth century; and mention is made of it in the writings of Dr. Bollmann, who in 1661 produced a monograph on Pyrmont. The other natural curiosity is the Dunsthöhle, a cave, from the mouth of which considerable quantities of carbonic acid constantly issue. The approach to this cave is crateriform, and the bottom of the crater, to a height of about eighteen inches, is always filled with carbonic acid, whose deadly effects are shown by the number of birds which are daily killed by attempting to feed in the bottom of the crater, and by the fact that some fifty suicides are recorded to have taken place at this gloomy spot.

Pyrmont owes its reputation to its iron-waters, and it possesses three principal springs—the *Stahl-brunnen*, the *Helenen-Quelle*, and the *Brodel-brunnen*. The first two are used for drinking, and the latter exclusively for supplying the baths in the great bathing-house. The composition of each of these springs is similar. The *Stahl-brunnen* contains 2.71308 parts of solids in every 1000 parts of water, and of these carbonate of lime, sulphate of lime, and sulphate of magnesia form more than two-thirds (the quantity of the latter being 0.45329 in 1000). Bicarbonate of iron is present to the extent of 0.07707 in 1000 parts of water—amply sufficient to give a distinct chalybeate taste. That which gives a distinctive character to the Pyrmont water and constitutes its most pleasant quality is the large amount of free carbonic acid, amounting to between 1200 and 1300 cubic centimetres in the 1000 grammes of water. The temperature is 12° C. (50° F.); and the water as it bubbles into its basin is cool, brilliant, sparkling, and very pleasant to taste. Pyrmont, considered with regard to its iron strength, ranks high among the chalybeate springs of Europe. It is very much stronger than Tunbridge Wells, and takes rank with Schwalbach, and before Spa and Rippoldsau. It contains more carbonic acid than Spa, but much less than Schwal-

bach. Pyrmont has also a brine spring, containing from 1 to 3 per cent. of salt, with ample bathing arrangements. Pyrmont is 400 feet above the sea-level, and the air is fresh and invigorating. The visitors are mainly of the female sex, and, as is the case at all iron springs, anæmic girls form the greater proportion of the cure-guests. There is a fashion in all things, and baths and health-resorts all have their day. Some say that Pyrmont's day is past, and that St. Moritz and other mountain chalybeates have effectually superseded it. I doubt this. Pyrmont has claims which are incontestable, and charms which age alone can give; and I believe that ere long, like Rip van Winkle, it will awake from its sleep of fifty years, renew its youth, and again become a fashionable resort.

(To be concluded.)

Obituary.

EDWARD MERYON, M.D., F.R.C.P.

By the sudden death, on the 8th inst., of Dr. Edward Meryon, at his residence, Clarges-street, Mayfair, the profession has sustained the loss of an accomplished and practical physician, and those who knew him a trusty and sincere friend. In the practice of his profession he not only brought his great professional experience to bear thoughtfully and conscientiously in every case in which he was consulted, but his kind and friendly sympathy was ever called into exercise as an auxiliary to his skill. He was single-minded, liberal, and accomplished, and his well-stored mind rendered his society at once entertaining and instructive.

Dr. Meryon was the author of several works, amongst the more important of which may be mentioned "The History of Medicine," "The Physical and Intellectual Constitution of Man," "Practical and Pathological Researches on the Various Forms of Paralysis," "The Functions of the Sympathetic System," &c.

In the memory of a large number of old acquaintances, especially many members of the Athenæum Club, he will long live as the type of a good, noble, and true-hearted gentleman.

JAMES SMITH WALTERS, Esq., F.R.C.S.

THIS gentleman died at his residence in Matlock-street Bakewell, on Saturday, Nov. 6th, after rather a short illness, of heart disease. Mr. Walters came of a respectable family at Cheadle, Staffordshire, and was educated at Repton grammarschool, and was afterwards pupil of the late Mr. Shaw, of Wirksworth. Mr. Walters had spent a long and useful life (over fifty years) in Bakewell. He held the appointment of surgeon to the Duke of Rutland and his household when at the Woodhouse and Longshaw Lodge; he was medical officer of the workhouse and district of the Bakewell Union, under the board of guardians, from its commencement in 1838 until the last few years; surgeon to the Volunteer Corps, which appointment he held with great pride and pleasure; also surgeon to the Odd Fellows and other societies in the town and neighbourhood, and was much and deservedly respected by a numerous circle of acquaintance.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on Tuesday last:—

Bayes, Frederick Thomas, Walsingham, Norfolk.
Blakesley, Henry John, Birmingham.
Burrows, Henry Chambers, L.R.C.P. Edin., Harrowby.
Cotterell, Edward, Rochester.
Cuffe, R. E. Gilhurst, Horncastle.
Fuller, Herbert Knowles, Basingstoke.
Gosse, Hope Wilkes, Hastings.
Gutierrez, Ponce Ignacio, M.D. Paris, Paris.
Haslam, Geo. James, M.D. Queen's Univ. Irel., Manchester.
Hoare, Alfred, Chapel-street, Park-lane.
Lyle, Samuel Henry, Liverpool.
Mackenzie, J. F. Edward, Newcastle-upon-Tyne.

Pryn, William Wenmoth, L.S.A., Saltash, Cornwall.
Sanders, Charles, Cheshunt, Herts.
Saunders, John Charles, Sheffield.
Strickland, Charles Edward, Warwick.
Waldron, John, Moulsoford, Berks.
Wasse, Gervas Miles, L.S.A., North Taunton, Devon.

The following were admitted Members on Wednesday last:

Bevor, W. Calverley, M.B. Edin., Workop.
Coffin, Arthur Blount, Holford-square.
Cutfield, Arthur, L.S.A., Lee, Kent.
Dummere, Howard Howse, Victoria Dock-road.
Fuller, Henry Roxburgh, Granville-place, W.
Griffiths, Philip Rhys, Aberdare.
Hall, Ben, Huddersfield.
Horsley, V. A. Haden, Kensington.
Jenkins, Thomas Griffiths, L.R.C.P. Edin., Ruthin, N. Wales.
Locker, Edward Hawke, Highgate.
McDonnell, James O'Malley, M.D. Queen's Univ. Irel., Duke-street, S.W.
Owen, Charles Richard, Fulham.
Roper, Arthur Charles, Exeter.
Smith, John, L.S.A., Commercial-road.
Trott, Dudley Cox, Ledbury-road.
Tweedy, Charles, Northallerton.
Willey, Charles Henry, M.B. Edin., Leicester.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 11th inst.:—

John H. Jones, Howard L. Smith, Henry Roberts, and Charles A. Morris, St. Bartholomew's Hospital; William F. Webster, St. Mary's Hospital; James Merces, Bengal and Cambridge; Edward N. Sheldrake, University College; and George B. Hicks, London Hospital.

Of the 61 candidates examined on the 9th, 10th, and 11th instant 20 failed to satisfy the Board, and were referred for three and one candidate for six months' further anatomical and physiological study.

UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent Second M.B. Examination:—

FIRST DIVISION.

Banks, William, University College.
Barnes, George Frederick, St. Bartholomew's Hospital.
Berry, Frederic Haycraft, Guy's Hospital.
Buckley, Samuel, Manchester Royal School of Medicine.
Castle, Hutton, St. Thomas's Hospital.
Day, Donald Douglas, St. Bartholomew's Hospital.
Hartley, Robert Nightingale, Leeds Medical School.
Harvey, Alfred, Queen's College, Birmingham.
Hayward, John Davey, University College.
Herschell, George Arie, St. Thomas's Hospital.
Jones, Robert, St. Bartholomew's Hospital.
Meek, John William, Guy's Hospital.
Money, Angel, University College.
Newsholme, Arthur, St. Thomas's Hospital.
Paddle, James Isaac, B.A., B.Sc. University College.
Parkes, Louis Colman, University College.
Penny, Edward, Guy's Hospital.
Permewan, Arthur Edward, University College.
Pollard, Bilton, University College.
Rice, Edward, St. Bartholomew's Hospital.
Rich, Arthur Creswell, St. Thomas's Hospital.
Saunders, Arthur Rich, University College.
Sellers, William, Edinburgh University and London Hospital.
Shaw, John, St. Thomas's Hospital.
Suckling, Cornelius William, Queen's College, Birmingham.
Wainwright, Robert Spencer, Guy's Hospital.

SECOND DIVISION.

Baddeley, Charles Edward, King's College.
Bowe, Francis, St. Bartholomew's Hospital.
Brooke, Henry Ambrose Grundy, B.A., Owens College and Guy's Hospital.
Claremont, Claude Clarke, University College.
Colborne, William Wriothley, University College.
Cuffe, Edward Meade, St. Bartholomew's Hospital.
Daiton, Norman, King's College.
Faulkner, John Thomas, Owens College.
Hurst, George, B.A. Sydney, University of Edinburgh and London Hospital.
Noddy, William John, B.A., University of Edinburgh.
Pickup, William James, University College.
Sayer, Mark Feetham, University College.
Walton, Robert Spence, University College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 11th:—

Hunt, Edgar Atlee, Montague-street, Russell-square.
Sturge, Henry Havelock, Highfield-road, Dartford.

The following gentleman also on the same day passed his Primary Professional Examination:—

Dadaboy Sorabji Schroff, Grant Medical College, Bombay.

THE H Division of the Metropolitan Police have initiated a grand entertainment to be given on the 2nd prox. in aid of the funds of the East London Hospital for Children. A similar festival held last year proved, we believe, a conspicuous success.

DR. TEMPLE CHEVALIER PALEY, of Cartmel, has been placed on the Commission of the Peace for the County of Lancaster.

MR. J. E. MITCHELL WILLIAMS, late medical officer in the Blean Union, has been granted a superannuation allowance of £50 a year.

It is now estimated that the number of lives lost in the fire at the lunatic asylum at St. Peter, Minnesota, does not exceed ten to fifteen.

TOWARDS the erection of a new fever hospital at Ayr about £5000 has been subscribed. In addition, the sale of the old building is expected to realise £2000.

THE storm which passed over Buxton on Monday appears, amongst other disastrous effects, to have done considerable damage to the new portion of the Devonshire Hospital in course of erection.

HOSPITAL SUNDAY was held on the 14th inst. in St. Helens and in Bootle, Lancashire. Collections in aid of the respective local medical charities were made in nearly all the churches and chapels of the towns.

THE "Globe" of Thursday states:—A burglary was committed yesterday morning at the private lunatic asylum of Mr. Harrington Tuke, at Chiswick. In order to gain admission to the premises the thieves must have first scaled a very high garden wall which surrounds the premises, and then got in through a back window. The premises were ransacked, and a large amount of valuable property taken away.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. J. Pateshall Jones, late of Fenchurch-street, bequeathed £300 to St. Bartholomew's Hospital (of which he was a governor) for the purposes of the Samaritan Fund. The late Mr. Thomas Blake of Cutsey has, it is stated, bequeathed £1000 to the Taunton and Somerset Hospital. St. Thomas's Hospital, Middlesex Hospital, and Westminster Hospital, each receive £19 19s. under the will of Mrs. A. M. Dobson, late of Pall Mall.

SOCIETY OF APOTHECARIES.—An important movement has been made by this Society. Hitherto the capital for the sale of drugs at the hall has been provided by members of the Society. Henceforth, however, the trading will be carried on by the Court of Assistants on behalf of the Society generally, the rights of the former proprietors having been purchased by the Court. This change has been made at the instigation of important bodies who had dealt with the Society. The reputation which Apothecaries' Hall has always had for the purity of the drugs to be obtained there will not be diminished one iota by the change, but will, if that be possible, be added to. The Society of Apothecaries is one of the City companies which have retained to the present day their ancient functions, to the advantage of the community, and the Society has devoted the funds at its disposal by giving prizes for competition in botany for registered medical students, prizes in botany also for young women, pharmaceutical chemistry, &c. The Society has also a fund for widows, and one for distressed members, &c. —*City Press.*

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BUTLER-SMYTHE, A. C., M.R.C.S.E., L.R.C.S.Ed., L.R.C.P.Ed., L.S.A.L., L.M., has been appointed Hon. Surgeon-Accoucheur to the Brighton and Hove Lying-in Institution and Hospital for the Diseases of Women and Children, vice T. F. Blaker, resigned.

CANNING, P. W. G., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Honorary Physician and Surgeon to the Charlottetown Hospital.

DAVIDSON, J., M.R.C.S.E., L.S.A.L., has been appointed Resident Accoucheur to King's College Hospital.

DILLON, J. T., M.D., M.Ch., has been appointed Medical Officer for the Ballyhorgan Dispensary District, vice Kenny, deceased.

EVANS, W. G., M.R.C.S.E., has been appointed Assistant House-Surgeon to King's College Hospital.

FARMER, S., M.R.C.S.E., has been appointed House-Surgeon to King's College Hospital.

FLIGG, W., M.B., has been appointed Resident Physician to the Sick Children's Hospital, Edinburgh, vice Brodie, whose term of office has expired.

GREEN, C., M.B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health to the Gateshead Urban Sanitary Authority, at a salary of £120 per annum.

GUTTERIDGE, E. P., M.R.C.S.E., L.S.A.L., has been reappointed Port Sanitary Officer for Maldon, until March 25th. £10 10s.

LAWFORD, J. B., M.D., L.R.C.P., M.R.C.S.E., has been appointed Ophthalmic Assistant to St. Thomas's Hospital.

MACARTNEY, T. L., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Medical Officer and Public Vaccinator to the Northern District of the Forde Union, vice Jones, resigned.

MASTER, H. H., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the First District of the Thingoe Union.

MORGAN, J. H., F.R.C.S., Assistant-Surgeon to the Hospital for Sick Children, has been appointed Assistant-Surgeon to the Charing-cross Hospital.

MURRAY, G. S., M.D., M.Ch., has been appointed on the Honorary Staff of the Bollingbroke House Hospital, Wandsworth-common.

O'MEARA, T. P., M.B., L.R.C.S.I., has been appointed Resident Medical Superintendent of the Carlow District Lunatic Asylum.

PENNY, W. J., M.R.C.S.E., has been appointed House-Surgeon to King's College Hospital.

PHILLIPS, J., M.R.C.S.E., has been appointed Assistant House-Accoucheur to King's College Hospital.

POTTS, J. A., M.B., M.R.C.S.E., has been appointed House-Surgeon to the Royal Maternity and Simpson Memorial Hospital, Edinburgh, vice W. Bassett, M.B., resigned.

POWELL, S., L.S.A.L., has been appointed Assistant House-Physician to King's College Hospital.

RANKING, J. E., M.A., M.D., has been appointed Physician to Tunbridge Wells Infirmary, vice J. R. Wardell, M.D., F.R.C.P., resigned.

RICHARDSON, C. B., L.R.C.P., M.R.C.S.E., has been appointed Assistant House-Physician to St. Thomas's Hospital.

RYAN, J. M., M.B., L.R.C.S.I., has been appointed Medical Officer to the Third Ward District of the Colchester Union.

SAER, Dr. P., L.R.C.P.Ed., L.R.C.S.Ed., L.S.A.L., has been reappointed Medical Officer of Health for Pembroke.

SHAW, J., M.B., M.R.C.S.E., L.S.A.L., has been appointed Resident Accoucheur to St. Thomas's Hospital.

SILK, J. F. W., M.R.C.S.E., L.S.A.L., has been appointed House-Physician to King's College Hospital.

STEEFOX, J. B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the First District of the Oldham Union.

STODDART, Mr. F. W., has been appointed Public Analyst for the Borough of Chard, vice Stoddart, deceased.

STURGE, W. A., M.D., has been appointed Physician to the Royal Free Hospital, vice O'Connor, deceased.

SWALE, H., L.R.C.P., M.R.C.S.E., L.S.A.L., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

WALL, E., M.D., has been appointed Medical Officer to the Courcy's Dispensary District of the Klusale Union, vice Magner, resigned.

WALLACE, R. S., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer to the Arnold District of the Basford Union.

Births, Marriages, and Deaths.

BIRTHS.

DALY.—On the 17th inst., at 101, Queen's-road, Dalston, the wife of Frederick H. Daly, M.D., of a son.

GODSON.—On the 15th inst., at Grosvenor-street, W., the wife of Clement Godson, M.D., M.R.C.P.L., of a son.

GOODING.—On the 11th inst., at Heath Lodge, The Grove, Blackheath, the wife of Ralph Gooding, Esq., B.A., M.D., F.R.S., of a son.

GRANT.—On the 11th inst., at York, the wife of Surgeon-Major R. A. P. Grant, M.A., M.R.C.S.E., Army Medical Department, late 43rd Light Infantry, of a daughter.

RAVEN.—On the 13th inst., at Barfield House, Broadstairs, the wife of Thos. F. Raven, L.R.C.P., of a daughter.

SEAMAN.—On the 10th inst., at Ledbury-road, the wife of Dr. W. C. Seaman, Deputy Inspector-General, Army Medical Department, of a son.

STOCKS.—On the 14th inst., at Courland, Wandsworth-road, S.W., the wife of Frederick Stocks, M.R.C.S.E., of a daughter.

WILLS.—On the 12th ult., at Julfa, Isfahan, Persia, the wife of Charles James Wills, M.D., of a daughter.

MARRIAGES.

HOFFMEISTER—ROBY.—On the 16th inst., at Holy Trinity, Paddington, by the Rev. J. C. Hose, assisted by the Rev. C. W. Whitfield, Dr. John B. Hoffmeister, of Brighton, second son of Dr. Hoffmeister, Surgeon to the Queen, of West Cowes, Isle of Wight, to Fanny Georgiana, youngest daughter of C. J. Roby, Esq., of 50, Gloucester-gardens, Hyde park. No cards.

WILLIAMS—HIGHMORE.—On the 27th ult., at the Abbey Church, Sherborne, Dorset, by the Rev. F. E. Williams, D.D., of Reading (uncle of the bridegroom), assisted by the Rev. G. C. Hilbers, Rector of St. Thomas's, Haverfordwest (cousin of the bride), and the Rev. W. H. Lyon, Vicar of Sherborne, William Henry Williams, jun., M.R.C.S.E., L.M.C.P.L., of Sherborne, to Louisa Blanche, daughter of William Highmore, Esq., M.D., of Sherborne, Dorset.

DEATHS.

DREW.—On the 1st inst., at Cathart House, Broadstairs, Henry Pye Lewis Drew, M.R.C.S.E., late of Gower-street, London, aged 69.

GARDNER.—On the 14th inst., at Lansdowne-crescent, John Gardner, M.D., in his 77th year.

HART.—On the 14th inst., at Stone's End House, Southwark, S.E., Walter Hart, M.R.C.S.E., L.S.A.L., &c., in his 57th year.

PERKS.—On the 12th inst., at Burton-upon-Trent, Sarah Elizabeth, the wife of Charles Perks, L.R.C.P., M.R.C.S.E., &c.

ROSS.—On the 11th inst., at Stockport-road, Donald Ross, M.D., in his 36th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

ECONOMICAL VALUE OF GOOD COOKING.

THE importance, from a health point of view, of good cooking is universally acknowledged. The economical aspect of the skilful preparation of food is not, perhaps, quite so obvious. This point, however, has been strikingly illustrated in the Lambeth Union, the guardians of which have been informed by Dr. Sloper that by proper cooking the waste in meat has been reduced from 57 per cent. to 40 per cent.: a result which will effect a saving to the parish of £356 per annum.

Mr. Henry Sugden.—The underselling in the matter of the club appointment is very bad. The other case is not stated with sufficient clearness for us to be able to express an opinion.

Professor G. Buchanan, (Glasgow.)—A short account of the case will be acceptable.

Young Practitioner has not enclosed his card.

TREATMENT OF HÆMORRHOIDS BY CRUSHING.

To the Editor of THE LANCET.

SIR,—Permit me to offer a few remarks in reply to the letter of Mr. Clarke, which appeared in your issue of the 30th ult. It is in the nature of things that every new invention, however successful, should receive a certain amount of adverse criticism, and perhaps my addressing you on the present occasion would be "better honoured in the breach than in the observance."

Doubtless when your correspondent penned his letter he had not read mine inserted in your issue of July 24th, p. 158. I gave as a reason for supplementing Mr. Pollock's remarks the fact that he had not given his theory as much credit as it deserved, and I quoted four cases in which the operation by crushing was most successful. Since then its superiority over other operations has been demonstrated again and again. Mr. Clarke speaks of a clean wound being left by my clamp, while in point of fact it leaves only a thin shred or fringed remnant no thicker than a stout piece of paper, and which soon separates, and from first to last there is an entire absence of sensation. I may further add that the use of ligatures is the exception rather than the rule, and even occasionally if a small one is applied to any oozing point, it is unaccompanied with pain.

I may add, in aid of Mr. Pollock's theory, the fact that gentlemen of considerable experience and eminence in the profession would not abandon all other methods in favour of his, unless they were fully convinced of its superiority in every way.

In conclusion, I would ask your readers, in the cause of humanity, to give the operation by crushing a fair trial, as the convalescence of the patient is speedy, and unattended with any pain or inconvenience.

I am, Sir, yours faithfully,

St. George's Hospital, Nov. 1880.

R. F. BENHAM.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions on Anatomy and Physiology submitted to the candidates at the primary examination for the diploma of Membership on the 5th inst., when 61 candidates presented themselves (Anatomy from one to three P.M.), when they were required to answer any four out of the six questions, and no more:—

1. Describe the fibula, with its muscular and ligamentous attachments.
2. Describe the deep cervical fascia.
3. Describe the masseter; its relations, attachments, and uses.
4. Give the dissection necessary to expose the superior profunda artery. Describe its course and anastomoses.
5. The abdomen being opened, give the steps to be followed for removal of the liver, and describe its under surface when dissected.
6. Give the cutaneous distribution of the nerves of the lower extremity below the level of the crest of the ilium and Poupart's ligament.

The following were the questions on Physiology:—

1. Describe the minute structure of bone. What is its chemical composition?
2. Describe the mucous membrane of the duodenum. What changes does the food undergo in this part of the alimentary canal?
3. Describe the phenomena of the coagulation of the blood, and the circumstances by which it is modified.
4. Describe the movements of respiration. How are they performed, and in what way are they modified by age and sex?
5. What is meant by the term "common sensation"? How is the degree of tactile sensibility estimated? and to what extent does the acuteness of sensibility vary in different parts of the body?
6. Describe the minute structure of nerve-fibres. Classify nerves according to their functions. Give examples of each class.

Mr. G. R. Gilruth.—We cannot insert our correspondent's letter. His views are most impracticable.

"THE CHLOROFORM DEATH-BILL FOR TWELVE MONTHS."

To the Editor of THE LANCET.

SIR,—Those who still believe that chloroform is the most safe and efficient anæsthetic have considerable reason to complain of Dr. Jacob's paper in your issue of Nov. 6th. They are branded with the imputation of an unfair suppression of the true mortality bill, from which charge the advocates of ether assume that they are free. A chloroformist's irresponsibility for an accidental death is called in question, and the way is prepared to prefer a serious legal charge against him. How far such a charge might be sustained against a country surgeon it is impossible to say; but surely a metropolitan coroner would dismiss Dr. Jacob's opinion if advanced against a metropolitan surgeon. Is it fair to assume that the statistics as to the comparative frequency of the use of chloroform and ether compiled in 1876, during the last ether frenzy, are applicable now? Or is it not more in accordance with fact to say that ether has been a second time weighed, and found wanting? Before any such dogmatic denunciation as Dr. Jacob's can be accepted, it must be backed up by recent statistics drawn from hospital practice, and fairly detailed. Only such statistics could embody the results of the recent trial of ether. I say from hospital practice, because a country surgeon has often to operate and administer an anæsthetic without any assistance whatever, and it is obviously unfair to place a death under such circumstances in the same category as one occurring in hospital. I have never seen a death from chloroform, and I have seen most serious symptoms from ether, though not actually fatal. I would not condemn ether on a small experience; but I will not forsake chloroform while my own experience tends in its favour until I see more reason than is contained in your contributor's paper.

I am, Sir, your obedient servant,

Guernsey, Nov. 8th, 1880.

J. AIKMAN.

To the Editor of THE LANCET.

SIR,—In your impression of the 6th instant the following passage occurs in a paper by Dr. Jacob, on the mortality from use of chloroform: "As regards locality, two deaths took place in the Edinburgh Infirmary, where, I believe, ether is not in use," &c. I have just returned from Edinburgh, and beg to intimate that in a series of Mr. Walker's and Dr. Argyll Robertson's operations, which I witnessed there (ophthalmic department), ether, or a mixture of equal parts of chloroform and ether, was the anæsthetic employed. In no instance did I see the pure chloroform given. By employing this mixture, so strongly recommended and so much used by the late Dr. Tanner, there can be no doubt that the sedative action of the chloroform is greatly lessened, and it is thus safer, with the advantage of being much more speedy in producing the required condition than is simple ether.

Yours faithfully,

JAS. DENHAM BRADBURN, F.R.C.S. Edin.

Golden Cross Hotel, W., Nov. 8th, 1880.

Mr. J. H. Drummond.—The advertisement is very objectionable, and demands the protest of the profession in Australia.

Mr. Arthur Pearce.—Messrs. Cornish, Publishers.

STIMULANTS IN WORKHOUSES.

THE subject of stimulants in workhouses has recently attracted the attention of boards of guardians in various parts of Ireland, more particularly in Cork, Wexford, Waterford, and Dublin, and petitions have been adopted in many unions, requesting the Local Government Board for Ireland to include stimulants under the head of medicines. The real object of this suggestion is to classify stimulants under the head of drugs; and should this concession be obtained, half their cost would necessarily be paid under the Medical Charities Act.

DIPHTHERIA AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—Most of your readers must have been struck with the singular fatality attendant on the five recorded cases of diphtheria in St. George's Hospital. Dr. Whiphram, in his concluding remarks, admits that the results of the treatment in the above cases were most unsatisfactory. I confess I was not surprised at the results from the treatment adopted. I am aware that there is a large section of the profession who treat diphtheria with tonics and stimulants *ab initio*, which I never did, neither could I understand the *rationale* of such treatment, as the secretions are invariably in a disordered condition, and the blood contaminated with a *materies morbi*—*ergo*, the *methodus medendi* is manifestly to start with alterative aperients, salines, and diaphoretics, and thus aid nature in eliminating the effete material under which she is so distressed. Under this plan of treatment my practice and experience of over thirty years have been most successful, having only witnessed two deaths, and these two happened in delicate children, whom I was called to attend after they had been ill two or three days with the disease, and which I discovered had travelled into the larynx on my first inspection. I have consequently looked upon diphtheria as a curable malady, especially if called in to treat it in seasonable time. I have generally commenced by washing off the fungus deposit with a strong solution of nitrate of silver (one drachm to the ounce) with a camel-hair brush, and in many instances have been successful in removing the whole or major portion of the deposit before leaving the patient. I continue daily to use the same application so long as any of the fungus is to be observed upon the membrane. I have sometimes used in like manner equal parts of carbolic acid and glycerine (locally nitrate of silver solution), but I prefer the nitrate of silver application.

The internal remedies with which I have started have been a small dose of calomel, with senna or scammony powder in children, or with the compound colocyth pill for adults; a saline mixture, with chlorate of potash, solution of acetate of ammonia, and spirit of nitric ether every three or four hours; the diet, beef-tea, milk, barley-water, and cocoatina. At the end of two or three days, the secretions having improved, and the febrile symptoms having subsided, I then give a dose, two or three times a day, of a combination of bark, with chlorate of potash, dilute hydrochloric acid, and spirit of chloric ether, and in some cases a little brandy or port wine, with their mutton chop, &c., complete their convalescence.

Upon referring to the powerful tonic and stimulating treatment in Dr. Whiphram's first case, it would appear from the report that the symptoms indicated high action with power; "pulse 125, fairly strong and regular"; nevertheless, the child at the age of six years had ten minims of the tincture of perchloride of iron, with two minims of dilute nitro-hydrochloric acid, in only two drachms of water every two hours, with ten ounces of port wine daily, strong beef-tea and milk, of each two pints! This little patient was admitted on April 21st, and died at 9 P.M. on the day following. At the post-mortem examination no membrane was found; but the mucous membrane of the fauces, larynx, and trachea was intensely congested, &c.

Passing over the others, who had similar treatment with the same results, I cannot help making special notice of Case 4, a probationer, aged thirty-three, who had been in her usual good health, but had been in attendance for two days upon the two fatal cases of diphtheria. She was taken ill with sore-throat on the evening of the 23rd April, and in three days she succumbed under similar tonic and stimulating treatment, aided by most assiduous attention from Dr. Whiphram and the house-physician!

It is a pity the profession cannot agree upon the pathology and treatment of diphtheria.

Yours truly,
Earl's-court-road, W., Nov. 11th, 1880.

E. MAY, M.R.C.P.

CALF LYMPH.

To the Editor of THE LANCET.

SIR,—As Dr. Cook has kindly undertaken the work, which, from its importance, I regret the Government did not see fit to take into its own hands, and in which I wish him every success, I would venture to suggest that instead of supplying tubes, he should take his lymph on points. I myself for several years have hardly ever vaccinated except with calf lymph obtained from Brussels, with which at first I was very unsuccessful. This Dr. Warlomont attributed to my use of lymph preserved in tubes, and I think I am right in stating on his authority that calf lymph, unlike human lymph, is best preserved on points. At any rate, by using points, I now rarely fail, more especially since I have used Hilliard's vaccinator.

Clapham-common, Nov. 1880.

Yours truly,

BEN. DUKE.

INTUSSUSCEPTION IN A PIGEON.

At a recent meeting of the Société de Biologie in Paris, M. Magnin showed a specimen of intestinal invagination from a pigeon, which died a few hours after seizure. The invagination was apparently provoked by the presence in the intestines of a large number of ascarides.

Locum Tenens.—The question is legal, not medical. In the absence of a definite contract, our correspondent must make the best terms he can without going to law.

"DENTAL-SURGEONS," "SURGEON-DENTISTS."

To the Editor of THE LANCET.

SIR,—I was surprised to find on reading Mr. H. Sewill's letter on the above subject that he had so misconstrued Mr. Napier's words as to convey a false impression of their literal meaning, and to lead one to the conclusion that he (Mr. Napier) was under the belief that "the Dental Act had for the first time conferred upon unqualified dentists the right to adopt the title surgeon-dentist or dental-surgeon." Permit me to say that it was chiefly through the instrumentality of the Association of Surgeons practising Dental Surgery (of which Mr. Napier is a Fellow) that the Dental Practitioners Bill was so altered as to preclude that right, which it otherwise would have conferred on the unqualified—an Association, moreover, numbering amongst its Fellows some of the most honoured and scientific members of this branch of the medical profession.

Yours faithfully,

Portland-place, W., Nov. 15th, 1880.

J. HAMILTON CRAIGIE.

To the Editor of THE LANCET.

SIR,—In the interest of medical reform, Mr. Henry Sewill's statement in your last issue ought not to be allowed to pass unrefuted. Mr. Sewill asserts that unqualified dentists possessed "a right" to adopt the title of "surgeon-dentist" before the passing of the Dental Act of 1878, which is wholly and absolutely incorrect. He asserts also that a "test case" was taken into the Appeal Court, presided over by the Lord Chief Justice; but I maintain that no such case was at any time whatever taken either into that Court or any other Court. I maintain, moreover, that neither magistrates nor judges have on any occasion been called upon to decide whether it was lawful or not for unqualified persons to assume the title of "surgeon-dentist"; and I now, in the interest of future—I hope I may with accuracy say impending,—medical legislation, call upon Mr. Sewill to state publicly the details of the case which he tells us was "pooh-poohed" out of Court by the Lord Chief Justice. The assertion that unqualified persons should have a "right," for the purpose of gain, to commit a fraud upon the public by representing themselves to be qualified persons is, or ought to be, revolting nonsense to the common sense of the profession, and especially so to the common sense of those who are aware of the fact that we have in existence a "Statute of Fraud."

I am, Sir, your obedient servant,

Stockwell-road, S.W., Nov. 15th, 1880.

R. H. S. CARPENTER.

To the Editor of THE LANCET.

SIR,—Permit me to respectfully offer a few brief observations, in justice called for by Mr. W. F. Donald Napier's letter on the above subject, which appears in your issue of the 6th inst.

It must be admitted on all hands that it is scarcely fair to include in the same category with unqualified pretenders skilled dental licentiates, who (in their speciality) are as fairly educated as "surgeons practising dentistry."

The Council of the Royal College of Surgeons in Ireland, having diligently considered the propriety and expediency of conferring their "Dental Licence" as a "supplementary diploma," have, in the end, adhered in principle to the system which has produced such good results in the case of the English College of Surgeons. Few dentists, owing to their (almost incessant) practical work, and to the demands which it makes on their energies, can ill spare the time necessary to master the "domain of general surgery"—a task which in the end would be productive of little fruit in after-life. A not over-generous public would badly repay for the sacrifice of so much time and trouble.

In conclusion, I would ask all "surgeons practising dentistry" to "let by-gones be by-gones," and to unite with dental licentiates in their joint efforts to expurge the "Dentists' Register" from the ignoble throng who degrade its pages.

Yours truly,

Dublin, Nov. 11th, 1880.

FRANK T. PORTER, F.R.C.S.I.

APPLICATION OF CALOMEL DUST IN THE TREATMENT OF PTERYGIUM.

To the Editor of THE LANCET.

SIR,—I desire to call the attention of ophthalmic surgeons to a new and, I believe, most effective treatment of pterygium. It consists in the daily application of calomel dust. This disease is very prevalent in Tokio, and for several years in a considerable ophthalmic practice I have used this application with marked benefit in all cases, and in many the cure has been so complete that no trace remains of the affection. I have long tried the old methods with the usual disgusting want of success; but, so far as my own practice here goes, I have now confidence in being able to cure the disease with hardly any risk of failure. Old and fibrous growths are stubborn, but even these have sometimes yielded.

Your obedient servant,

HENRY FAULDS, L.F.P. & S.

Tsukiji Hospital, Tokio (Yeddo), Japan, Sept. 1st, 1880.

M.R.C.S., L.S.A.—The following hospitals are represented at the Court of Examiners of the College:—St. Bartholomew's, by Messrs. Holden (the late President) and Savory; Guy's, by Messrs. Birkett (the Chairman) and Cooper Forster; St. George's, by Mr. Holmes; Middlesex, by Mr. Hulke; Cambridge, by Dr. Humphry; King's College, by Mr. Wood; University College, by Mr. Marshall; and the London, by the recently elected member, Mr. Jonathan Hutchinson, who took his seat on Tuesday last.

Mr. Julius Caesar.—The papers, if forwarded, shall have due attention.
Dr. A. Downes is thanked.

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—It may interest your readers to learn that the Hebrews were of the same opinion as Dr. Mortimer Granville as regards the influence of the relative arduity of the parents in the determination of sex. In a recent translation by Dr. Rabinowicz of all the passages of the Talmud concerning medicine will be found the following extract from the treatise entitled "Nidah": "On lit dans une beraïtha: si la femme donne sa semence (le sang) avant l'homme, le fœtus sera un garçon; si c'est le mari qui donne d'abord sa semence (le sperme), le fœtus sera une fille. On peut donc si on veut avoir des garçons; l'homme peut pour cet effet retarder son émission de sperme pour laisser la femme donner sa semence avant lui. Rabba dit qu'on obtient des garçons en répétant le coït; car, dit Raschi, la femme excitée par le premier coït émettra son sperme avant l'homme pendant le second." Yours faithfully,
Paris, Nov. 1880. W. O. J.

To the Editor of THE LANCET.

SIR,—On June 22nd, 1880, I attended a woman in her third confinement, who was delivered of twins of different sex, followed by a single placenta. The children were both about the ordinary size of single children. There was only five minutes' interval between the two births, and the placenta followed the second child in two minutes. They were both head presentations.

I merely mention this case as an answer to the query in last week's LANCET. Still, I look upon evidence against (as well as for) any theory as being of value in arriving at a just conclusion. Of course one case goes for very little, but there may be others to place with it; although a number of such cases would not necessarily upset the hypothesis laid down by Dr. Mortimer Granville last week.

There is another point I would mention. The mother in the above case said her female relatives had had twin births; and on other occasions I have heard the same remark.

I am, Sir, yours faithfully,

Leeds, Nov. 15th, 1880.

G. HODGSON HIGGINS.

* * * THE question seems to be whether the so-called "placenta" in these cases is anatomically single, or really composed of two placentæ, perhaps closely united.—ED. L.

C. P. M.—The question should not be unnecessarily raised. We are not prepared to say what legal complications might arise.

M.B.—Yes.

L.R.C.P. Lond. had better apply to the Secretary of the Order, St. John's-gate, Clerkenwell.

THE USE OF IMPURE MATERIALS IN ERECTING BUILDINGS.

To the Editor of THE LANCET.

SIR,—I may say, with reference to Dr. W. H. Murray's letter on this subject in your issue of Nov. 6th, that the Chinese builders bind their mortar together by means of a *pure white paper* made from the dried fibres of the bamboo. Their builders' specifications always regulate the proportions of this and every other article of the mortar used. They also finish off their walls with an exceedingly pure lime-mortar (sometimes made from shells of various molluscs), which leaves a perfectly smooth surface. No colouring matter is ever added, except in the case of temples, where oxide of iron is used. Yours truly,

Shepton Mallet, Nov. 8th, 1880.

F. PORTER SMITH, F.R.G.S.

Mr. Stanley Churton.—The article and advertisement referred to appear in THE LANCET of June 12th last.

Dr. Reed.—The request will be attended to.

SCHOOL-BOARD CERTIFICATES.

To the Editor of THE LANCET.

SIR,—I would feel much obliged if you could give me information on the following points:—

I am the house-surgeon of a provincial hospital, and in the out-patient department am daily applied to for School-Board certificates for sick children. 1. Am I compelled to give such certificates? 2. Am I entitled to remuneration for the same, and, if so, from whom can I claim it—from the School Board or from the parents?

Yours obediently,

Nov. 11th, 1880.

S. B. C.

A "FORLORN HOPE."

THE Newcastle Homœopathic Dispensary was entered by burglars some time since. It is needless to say the thieves "went empty away."

INFANTILE DIARRHŒA.

To the Editor of THE LANCET.

SIR,—In August last I took charge of a gentleman's practice in one of the smokiest and most densely populated manufacturing towns in the north. Whilst I was there infantile diarrhœa was epidemic, and on the very day my friend inducted me three babies died; but from that day to the end of my term, a period of exactly three weeks, I was so fortunate as not to lose a single case, although I must have attended close upon a hundred. In every instance I found the usual errors in dieting being committed—viz., starch feeding in one form or another (farinaceous), or else the using of boiled milk. I simply urged and insisted upon a return to strictly natural food—suckling where practicable, and milk-and-water where not. The only medicine, so to call it, I employed was a little weak lime and dill water, and in two or three apparently desperate cases I added a small quantity of brandy to the milk-and-water, and fed the poor little sufferers myself when they were passed the capacity to suck, and when the mothers were inclined to abandon hope and to relax their efforts, and, as I said before, I had the happiness not to lose one single case. I mention this fact in order to show that absolute success may be attained in this most fatal of diseases without having recourse to the perilous expedient of giving opium to very young children, as recommended by a correspondent from Middlesborough recently in your journal. Yours obediently,

Oct. 1880.

LOCUM TENENS.

FISH-EATING AND LEPROSY.

To the Editor of THE LANCET.

SIR,—In reply to Mr. Hutchinson's critical remarks (which are always worthy of attention) on my case of leprosy and my views on the fish hypothesis, I can only remind Mr. Hutchinson what I stated with reference to the small amount of good fish that the patient had taken during his thirteen years' residence in India, reported in your journal of the 30th ult., as a deduction from many and stringent inquiries at repeated intervals during some hundred visits whilst the patient was under my care at the hospital.

If the authorities—one a much-respected medical man, long resident in India, the other a gentleman of high social position, eighteen years resident in India—are willing to permit me to use their names and information publicly, with reference to the fish-eating and non-fish-eating districts of India and Africa, and their relation to true leprosy, I will do so at a future period, with other additional information on the subject. Meanwhile it would be a matter of great interest to hear the present opinion of Sir Joseph Fayrer and Dr. Vandyke Carter. Is true leprosy entirely due to the eating of fish (unwholesome) in large or small quantities? I am, Sir, yours &c.,

Sackville-street, Nov. 10th, 1880.

JAMES STARTIN.

SCHOOL HYGIENE.

To the Editor of THE LANCET.

SIR,—At a recent meeting of a provincial school-management committee, the question was discussed whether or not it is objectionable on sanitary grounds to employ as resident keeper of the premises a young man who has a young wife and two very young children. The minority opposed it, on the ground that if these children were attacked by any infectious disease incidental to childhood, the health of the pupils would thereby be threatened; but the majority, who saw no particular danger in this, carried the day. Your correspondent begs that you will give your opinion, and state also if any cases are known where schools have suffered in consequence of infectious children's diseases having occurred on school premises. Yours faithfully,

Nov. 8th, 1880.

S.

WANTED, A DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—I am anxious to get some hints for the successful treatment of the following case:—

The patient is a stout man, aged thirty-eight, and strictly temperate. About twelve years ago he had a fit. The medical man in attendance treated him for epilepsy. He had no return of the fits until four years ago, when he had another in bed. I examined his urine. Specific gravity 1020 (which has always remained at that), acid, and contained about one-sixth of albumen. He complains of a headache occasionally, after which an eruption of acne pimples comes out on his nose, also a warm feeling across the lumbar region. Sometimes he has severe pruritis of the skin of the legs. He has no swelling of the limbs or puffiness below the eyes; eats and sleeps well, and gains in weight. He said he had an attack of syphilis some years ago. I put him upon iodide of potassium. The albumen still appeared. After that a course of each of the following:—Bromide, iron, gallic acid, iodide of iron, buchu, uva ursi. No matter what he takes, it is all the same; albumen appears. His heart, lungs, and liver are healthy. I should like to know if this is a case of incipient Bright's disease, or is it a peculiarity in the patient?

If any of your readers would kindly give me their opinion on the case it would be much valued.

Yours faithfully,

November, 1880.

L.R.C.P.

ERRATUM.—In the description of Messrs. Millikin and Down's Spray given in our last week's issue, the bottle is mentioned as of "four" instead of *forty* ounces' capacity.

Lectures ON

THE RELATIONS OF SARCOMA TO CARCINOMA.

Delivered at the Royal College of Surgeons in June, 1880,

By HENRY TRENTHAM BUTLIN, F.R.C.S.,

ERASMUS WILSON PROFESSOR OF PATHOLOGY TO THE COLLEGE,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, &c.

LECTURE III.—PART II. CENTRAL TUMOURS OF BONE.

THE two tumours of the FIBULA may be regarded as a kind of appendix to the tumours of the tibia. They occurred during the middle period of life, were of the upper epiphysis, and both displayed a less malignancy than the corresponding subperiosteal tumours. Again, it is unfortunate that no autopsy was permitted of the fatal case.

The malignancy of the spindle-celled sarcoma of the FOOT is so marked and of such a kind that the case must be dealt with at greater length. It is recorded by Virchow in the *Krankhaften Geschwülste*.¹ The patient, a morocco-leather dresser, thirty-one years old, whose health had been always good until the early spring of 1858, suffered at that time from a sharp attack of pleurisy, from which recovery was speedy and apparently complete. At Whitsuntide he noticed a swelling of the dorsum of one foot, and at Michaelmas a second tumour appeared about the external ankle. In the spring of 1859 he began to cough and could no longer breathe with ease. These difficulties increased in severity, and in April caused his death. The second and third metatarsal bones were quite replaced by a soft medullary substance, blotched with old and recent blood, which touched the periosteum and cartilage in all directions, but did not extend beyond them. Several of the smaller tarsal bones contained similar medullary substance, which occupied the centre of each bone and left the cortex free. The osseous system, with these exceptions, is reported to have been sound. Both lungs were the seat of secondary growths, which on the left side projected between the layers of the pleura. But the condition of the glands is to me the most attractive feature of the case. One popliteal gland was diseased and medullary in appearance; the lower inguinal glands the size of walnuts and also medullary; the glands immediately above simply hyperplastic, but here and there exhibiting small medullary nodules; whilst the mediastinal glands formed a row of medullary growths. For my comfort's sake I would willingly have omitted this case or passed it by in silence, for it is the only one in the whole series of central tumours of which the sole explanation I dare offer is that the affection was conveyed through the lymphatic vessels. At present I am at a loss to conceive the reason of what I cannot but perceive is a deviation from the course naturally pursued by these tumours. But since the object, above all others, of this inquiry is to ascertain the truth, this case must be accepted with the others in the hope that so far from exhibiting an arbitrary deviation from a natural law, even its apparent irregularity may help to guide us to a more intimate knowledge of the laws which govern the course pursued by a malignant tumour.

The first case of the following group of tumours of the HUMERUS is also an example of glandular affection, but of a very different kind. The tumour, a round-celled sarcoma of the humerus, grew within the upper epiphysis. Eight months after its first appearance the patient died, apparently killed by the disease, for which no operation had been practised. For in addition to the tumour of the humerus a similar growth existed in the medulla of the other humerus, and a third tumour in the interior of one femur immediately below the trochanters. The mesenteric and retro-peritoneal glands were the seat of similar disease, but in no other organ or tissue of the body

were secondary tumours found. The relation of this gland-affection to the tumours of the bones is not clear, but the disease could scarcely have been conveyed through the lymphatic channels. The complete absence of any secondary affection in the other cases may probably have been due to their death from other causes at an early period of the disease. The same tendency to affect persons of a mature age observable in other central tumours is apparent in these tumours of the humerus.

The tumours of the ULNA and the RADIUS, whatever the variety of the sarcoma, attacked almost always the lower portion of each bone. A very modified malignancy is evident in four of the five cases, as well in the case that died as in those whose good health is recorded long after operation. For the fatal case is marked by the complete absence of secondary tumours.

The number of cases of tumour of the SCAPULA, like those of the pelvis, would be greater but for the difficulty of deciding on their origin.

The central tumours of the JAW are far more numerous than those of subperiosteal origin, but I suspect one of them would be more justly classed among the latter. It is the round-celled sarcoma, No. 47, which occurred in a child five years of age. It grew rapidly, and at the end of two months was resected with the portion of the jaw to which it was attached. In six weeks it was again removed, and after the second operation it speedily recurred again, and in seven months from the day it was first noticed the patient died exhausted. In the record of the case by Mr. Heath, in the *Pathological Transactions*,² the tumour is spoken of as evidently growing from the interior of the bone, but from the description I am unable to convince myself of this. Recurrence after operation, which was so marked a feature of the subperiosteal tumours, is noted only of two of these—that I have this moment mentioned, and a case in which the tumour was simply enucleated from the cavity in which it lay. Recurrence was speedy in both cases, but in the latter the progress of the recurrent tumour was very slow, for it was not removed until seven years after the first operation had elapsed, and even then was hardly larger than a walnut. The cases of myeloid disease are singularly complete. Every one of them was traced through many months, and more than one through several years. The first of the list is stated to have died of myeloid disease; this was not so. Although he suffered from three small tumours, two of the jaw and one of a single rib, his death was from exhaustion connected with mollities ossium. The admixture of earthy salts or bone is a noticeable feature in the tumours of the lower jaw.

The tumour of the STERNUM might fairly be included with the tumours of the skull, or might perhaps more rightly form one of a class to which I shall have occasion presently to refer, the members of which attack several bones almost at the same time.

The PELVIC tumour is of little interest unless it be compared with the subperiosteal pelvic tumours, but is of extreme interest as it bears upon the important question of glandular affection. It did not affect the lymphatic glands, and the reason for this forbearance may probably be discovered in its relation to the cavity of the pelvis, and therefore to the lymphatic glands. Almost the whole of the sacrum and coccyx was replaced by the new growth, which infiltrated the muscles posteriorly, but was limited in front by the periosteum, which separated it from the interior of the pelvis. It may be remembered that the pelvic tumours which affected the lymphatic glands were in each case without a covering of any kind, were of large size and grew directly in contact with the glands.

The tumours of the SKULL differ from the cranial subperiosteal tumours first and most strikingly in the much older patients they attacked, for the youngest of the four was nearly fifty years of age; second, in the fact that although three of them were of the vault only one produced multiple tumours of the skull. This one case too was singular in the affection of the glands which occurred as the disease progressed; and which was probably due to a continuous growth from the tumour of the occiput. As in the subperiosteal round-celled tumours, so in two of these there was widespread generalisation, chiefly in various bones.

This leads me to speak of a class of cases to which I referred when speaking of the tumour of the sternum—cases in which many bones are attacked almost simultaneously by sarcomatous disease. Such I imagine was the nature of a

¹ Bd. ii. s. 338.

² Vol. xix. p. 303.

case recorded by Dr. Moxon in the *Pathological Transactions*.³ It is described as "colloid cancer," the characters of which it undoubtedly presented, for the tumour consisted of large alveoli filled with gelatinous material. With the exception of numerous rounded nuclei in some of the alveoli, no mention is made of cellular elements; unless, therefore, we accept these as round cells, which had escaped destructive or degenerative changes, there is nothing to guide us to a diagnosis of the variety of sarcoma to which this presumably belonged. The patient, who was only twenty-three years of age, had never during life presented any signs from which it could be inferred that he was the subject of extensive osseous disease. He died apparently from hæmorrhage following the removal of some warts from his prepuce, an operation of the most trivial nature. The autopsy, however, discovered sufficient cause for death. The bladder was inflamed; the kidneys suppurating; numerous subperiosteal tumours of small size existed on the inner and outer tables of the skull; many of the vertebrae, from the skull as far down as the sacrum, contained growths of larger and smaller size; seven of the ribs of the right and four of those of the left side were affected in a similar manner. The largest of the tumours appears to have been that of the eighth left rib; it was swollen to the size of a large plum, completely destroyed the bone where it was seated, extended through the periosteum, which was still visible as a circular line in a section of the tumour, and infiltrated the surrounding muscles. None of the organs or other tissues of the body were affected except some of the bronchial glands, probably by continuous infiltration from the tumours of the ribs or spine. It cannot of course be absolutely averred that most of these tumours were not secondary to some one among their number; but their near equality of size, the absence of symptoms indicating long duration of any of them, and the absence of secondary affection of parts usually prone to such affection, all point to another origin than this. Probably several of the cases classed with the tumours of particular bones might more justly be grouped together as instances of general sarcoma of the bones, what has been called by Buch⁴ "multiple primary sarcomatosis of the medulla of bone." The cases in this table which appear to merit this appellation are the last three of those of the skull, that of the sternum, and perhaps the round-celled tumour of the humerus. All the tumours were round-celled, and the bones most frequently affected were the skull, the ribs, and vertebrae. Von Rustizky,⁵ in the short article in which he includes the case I have numbered 62, calls the disease in that particular instance "multiple myeloma," and regards it as a simple or innocent affection, a mere outgrowth of the medulla of the bones. But its rapidly fatal issue, the infiltrating nature of the growths, the vessels with walls composed of a single layer of round cells, are, I think, characters absolutely inconsistent with such a view. The names suggested both by Buch and von Rustizky do not completely cover all the conditions of the disease. For although most of the tumours are of central origin, some of them are superficial, the tumours of the skull especially, which grow, as in Dr. Moxon's case, on the outer and inner aspects of the bone. It may be that the tumour of the femur (No. 2), of whose rapid course and widespread generalisation I spoke yesterday, was an instance of this general sarcomatous disease of bones. Perhaps too, as a lesser affection of the same kind, may be included the disease of the tarsus and metatarsus, which took the form of isolated areas of tumour in the interior of several adjacent bones, but did not affect parts of the skeleton more distant. If this case be admitted, it forms the sole exception to the rule by which thus far all the tumours have been round-celled. So far from regarding this condition as one of simplicity or less malignancy, it should surely be regarded as one of exceeding malignancy, for the disease falls not upon a single structure, but almost simultaneously upon several or even many similar structures, and from any or from all of these may spread, either by continuous infiltration, or through the medium of the blood; this character of multiplicity it is which deprives the unfortunate subject of the sarcomatous disease of the last chance which might otherwise be given by its removal.

Hitherto I have dwelt almost entirely upon the characters of sarcomas of particular bones. Now let me, in conclusion,

point out a few important features, most of which are common to both central and subperiosteal growths.

First: their history and course. Speaking in very general terms, central tumours occur in persons older than those who are the subjects of subperiosteal tumours; for while the latter not uncommonly attack young subjects, or even children, the former are by no means rare in persons advanced in years. Again, the central tumours grow for the most part more slowly than those which originate beneath the periosteum. Injury is not credited with the production of a large proportion of the tumours of bone, nor does previous inflammation appear to exercise the influence which has been attributed to it.

Second: the physical conditions of the tumours previous to their removal, or to death, are interesting, especially in two particulars—first, their situation; second, their occasional pulsation. Let us take the second first, for it is more easily dealt with. A tumour of either origin may pulsate, but the symptom is more common in central than in subperiosteal tumours. It occurred in every variety of the former, only in the round and mixed-celled subperiosteal growths; and in either case only in tumours of certain bones—the femur, tibia, calvaria, and innominate bone. The total number of pulsating tumours of the long bones was much larger than of the other two, but the proportion was greatest in the tumours of the pelvic bone, in which it reached one-half. Where the cause of pulsation could be ascertained it was due in every case to an abundant supply of vessels of moderate calibre, which in some cases of blood-cyst poured their blood directly into the cavity of which the tumour appeared mainly to consist.

No problem has seemed to me so difficult as the unfolding of the laws which determine the situation of sarcomatous tumours. Long bones, short bones, and flat bones are liable to sarcoma, but not all bones equally, or even all the bones of each shape in equal proportion. The long bones of the lower extremity are far more frequently attacked than the bones of the arm and forearm, while the bones of the metacarpus and metatarsus are but rarely affected, the phalanges almost never. The flat bones of the skull, the scapula and the innominate bone, are all subject to sarcoma, but the skull bones most of all. None of the short bones are very liable to the growth of primary disease, and I have found no record of affection of the carpal bones. But this statement only very partially expresses what may be termed the power of selection exhibited by sarcomatous tumours. In the long bones they show a decided preference for the epiphyses or articular ends, and especially the tumours of central origin, for one articular end of each long bone. In the upper extremity it is the upper epiphysis of the humerus, the lower of the radius and ulna; in the lower extremity the lower epiphysis of the femur, the upper of the tibia and fibula. The explanation of this singular phenomenon may be attempted on various hypotheses, but none of them are satisfactory. It is possible the secret exists, not in one condition, but in a combination of conditions, one or the other of which may exercise an influence more prominent than the rest. As a fisherman oftentimes attaches several baited hooks to the end of a single line in the hope that, one failing, another may allure his prey, so let me bait those particular ends of the long bones, which are so frequently the seat of central tumours, with all the conditions I can find common to them, and abide patiently in the hope that the reason which evades us now may be one day found fixed to one or other condition, perhaps by someone more fortunate than myself. All these parts contain cancellous tissue in greater or less abundance; their position renders them liable to squeezes, blows, and injuries of various kinds; in the process of development of the bones they are the parts which are the first to ossify, the last to be united with the shaft; and the direction of the nutrient artery is from them, not towards them.

Third: after removal of the tumour, or death, a peculiarity is observed in the appearance of the subperiosteal tumours which does not exist in the central growths. They present, in the large majority of instances, a structure radiating from the bone, which indeed, I believe, is never absent if the material of which the tumour is composed is of such a nature as to allow it to appear. Rindfleisch⁶ mentions it, and ascribes it to a papillary formation. But it is not a papillary formation in the sense of resembling in structure a papilla of the skin or mucous membrane, but apparently is solely due to the manner in which the tumour grows or is developed.

³ Vol. xxii. p. 206.

⁴ Ein fall von multipler primärer Sarcomatose des Knochenmarks. Inaug. Dissert. Halle, 1873.

⁵ Deutsch. Zeitschrift f. Chirurgie, Bd. iii., s. 162.

⁶ Lehrbuch d. Pathologischen Gewebelehre, 4te Auflage, s. 544. Leipzig.

The chief growth takes place around the tiny vessels passing from the periosteum almost at right angles through the cortex of the bone; each of these becomes the centre of a column resting on the bone; and thus the stamp of radiation is impressed upon the tumour. A radiation of a similar kind may exist in inflammatory new formations originating beneath the periosteum. I have already referred to the rarity of osseous and cartilaginous transformations of the substance of central tumours, so common in subperiosteal growths.

Fourth: the progress and termination of both classes of tumours show that all sarcomata of bone may be malignant, but their malignancy is of widely different degrees, and displayed in various forms. Speaking generally, it may be said that central sarcomas are far less malignant than subperiosteal, and tumours of the bones more distant from the trunk than those of bones more near. The latter of these two statements is illustrated by the relative malignancy of the tumours of the tibia and of the femur, which has been referred to in each of these two lectures. The accuracy of the former statement may be tested as well by the cases which have come under my own observation as by the complete series of these tables. Of eleven patients with subperiosteal tumours of various bones of which I have taken notes, and which are included in the table, I know that nine are dead. The tenth, whose tumour was of the tibia, and for whom amputation was performed at the end of two months, was well when last heard of, fourteen months after operation. The eleventh was subjected to amputation only a few weeks ago. Of ten cases of central tumours here included, I have notes of the death of three, and of slow recurrence in one during seven years after enucleation, while four are known to have been well at periods respectively of one year, three years and a half, four years, and five years and a half after operation.

The least degree of malignancy is infiltration of contiguous structures, much more common in subperiosteal than in central tumours, and, though generally seen in tumours which become generalised in distant parts, not a necessary precursor of this more marked malignancy. Next in order to this continuous infiltration is affection of the lymphatic glands, rarely occurring in conjunction with subperiosteal, still more rarely with central tumours. It may be of the same nature as the affection of other organs where the disease is probably conveyed through the medium of the blood, as when glands having no lymphatic relation with the region primarily diseased become sarcomatous. Examples of this were alluded to in speaking yesterday of the tumours of the skull, and to-day the round-celled tumour of the humerus furnishes us with an instance among the central tumours. Or it may probably originate in continuous infiltration of one or more lymphatic glands by the primary disease, an opinion for which I have delivered reasons in the reports of several cases, but which I have not yet been fortunate enough to prove by actual dissection. For in those cases in which tumours of large size grew in the immediate neighbourhood of lymphatic glands, and in their growth destroyed them, I could not be sure whether the disappearance of the glands was due to their entanglement in the tumour or to transformation of their substance. And, since I am not able to affirm the contrary, it may be due to conveyance of the primary disease through the lymphatic channels, the common path by which most tumours affect the glands, but I venture to think the least common of the sarcomata of bone, if, indeed, it ever occurs; and for these reasons: the infrequency of glandular affection in connexion with tumours of bone, whether central or subperiosteal, the absence of glandular affection in cases of long-standing disease, and the absence of glandular affection when the disease has been permitted to run an uninterrupted course to death, and when one or more of the organs are the seat of the secondary growths. It might be thought that if the primary disease did not obtain access to the lymphatic channels directly from the bone, it yet might find an entrance into them when the soft tissues around the bone became involved. But probable as this appears in theory, it is contrary to the teaching of experience. It will of course be understood that every case of irritative or inflammatory enlargement of the glands has been carefully excluded. The last degree of malignancy is that in which growths appear in organs or tissues more or less remote from the part in which the tumour first was noticed; in most cases undoubtedly conveyed there by the blood, as when the interior of the heart or the lungs become affected; in some cases of less certain origin, as when the subcutaneous tissue

or the skin is the seat of secondary tumours and the lungs are free; and in some cases apparently due to distinct outbreaks of sarcomatous disease, either after a prolonged period of quiescence or in several parts almost simultaneously. Of all organs, the lungs are far more commonly affected than any other, and the tumours which exhibit the most marked tendency to widespread generalisation are the round-celled tumours. But the affection of the lungs and the generalisation of round-celled tumours are, as may be seen by a glance at these tables, both largely influenced by the situation of the tumour. It is the round-celled tumours of certain bones which are thus liable to become widely generalised, and the subperiosteal which are far more likely than the central tumours to affect the lungs.

If in these two lectures I have bestowed what appears to be too little attention on the effect which the structure of a tumour produces on its characters and course, it is because this effect has seemed to me to yield almost entirely to the far more potent influence exercised by the situation of the growth, and my desire to exhibit in its perfection the power of the latter has led me almost to neglect the former.

I cannot now enter at length into the question of operation, but still I cannot refrain from indicating how largely it is influenced by a more intimate acquaintance with the conditions of life of the tumours of different bones. Setting aside cases of multiple sarcoma and of tumours so situated that they cannot be removed, it seems as if no doubt can exist of the propriety of operation where the disease has not advanced too far. Its advantages are obvious. Complete removal of the primary disease arrests its continuous infiltration and terminates the dangers which are incidental to the mere presence of a tumour often of enormous bulk. For local recurrence may be regarded as an accident which may be absolutely prevented by removal, an accident almost unknown when, for example, the thigh is amputated for a tumour of the tibia. Nor does there seem sufficient ground to doubt that if the primary tumour were early enough removed, generalisation by the blood and affection of the glands may be prevented. Against these benefits the only disadvantage which can fairly be alleged is the danger of the operation itself, marvellously less at the present time than it was ten years ago, and not to be gauged by the horrible mortality exhibited in this table of central sarcomas.

The following general rules for operation may, I think, be gathered from a study of the cases in these tables.

For all subperiosteal sarcomas of the limbs amputation at the earliest possible date high up above the tumour. The nearer the tumour to the trunk the less likely is the operation to be successful, not only because the malignancy of these tumours seems generally to increase as they grow from parts more near the trunk, but because of the greater difficulty of allowing an area sufficiently wide above the growth. For subperiosteal sarcomas of the clavicle, the lower jaw and ribs, free resection of the tumour, and of the bone from which it grows. But with a diminished expectation of success depending upon the vastly-increased chance of recurrence after operation. For subperiosteal tumours of the pelvis usually no operation is of use, and for those of the skull none is admissible, partly because the tumours of the vault grow from both aspects, partly because in the majority of cases they are multiple.

For all tumours of central growth occurring in the bones of the extremities the chances afforded by amputation appear to be infinitely greater than for subperiosteal tumours. And for those of the leg, forearm, or even of the arm, when the tumour has not extended beyond the limits of the bone or periosteum, for amputation resection may be substituted. Nay, in some few cases, where growth is slow, and the bone not too widely expanded, the tumour may, with advantage be dislodged, or scooped out from its cavity through an opening in the wall. For central tumours of the lower jaw and clavicle, resection or enucleation may be practised with the best hope of success. But for central tumours of the pelvis and the skull usually no operation should be practised, in both cases because the situation of the tumour often places it beyond the reach of operation; in the second case, because the central, like the subperiosteal, tumours of the skull are often multiple.

THE treasurer of Addenbrooke's Hospital, Cambridge, has received 100 guineas, as a first instalment of the proceeds of Hospital Saturday in the town.

ON "TENDON-REFLEX" AS AN AID TO DIAGNOSIS IN DISEASES OF THE SPINAL CORD.

By THOMAS BUZZARD, M.D., F.R.C.P.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND
EPILEPTIC.

IN the following remarks it is provisionally assumed that the contraction of a muscle which follows a blow upon its tendon is of the nature of a reflex action. The adequacy of such an explanation is, I am well aware, contested by high authorities in physiology. Measurements of the interval of time which elapses between the blow and the contraction are thought to prove that this is too short for the phenomenon to be reflex. I cannot as yet consider this to be a conclusive objection, for whilst, of course, acknowledging the respect which is due to attempts at accurate measurement, experience shows that, even in very careful hands, where the question is one of delicacy—in the present instance it is a matter of a very few hundredths of a second—sources of fallacy are apt to occur in the experiments which vitiate the conclusion. It is quite conceivable, moreover, that a shorter period of time than is commonly needed for a reflex event is requisite for conduction through the centre, where, as in the present instance, the centripetal stimulation is in all probability unusually strong. Nor can we properly compare it with the time required for reflex from the skin, since the fact that in tabes, for example, whilst the skin-reflex is usually preserved intact, the tendon-reflex is always lost, shows that the conduction must, at least in some part of the course, take place through a different path.¹ At any rate, it seems advisable that at the present juncture the clinical facts should have due prominence, and there can be no question, I think, that they make out a strong *prima facie* case in favour of the reflex character of the muscular spasm. With the view of aiding in the consideration of the question from this point of view some rough diagrams are reproduced, which I have been long in the habit of using in order to illustrate the connexion between certain pathological changes in the spinal cord and the absence or exaggeration of "tendon-reflex." For the sake of simplicity, the remarks will be confined as far as possible to "patellar tendon-reflex" and "ankle clonus" as representatives of phenomena which may, as is well known, occur in connexion with other tendons and muscles.

The patellar tendon-reflex may be conveniently tested, in most instances, by the following procedure, which differs from that usually employed. The patient, who is seated, plants his foot firmly down at such a distance that the leg forms a little more than a right angle with the thigh. Whilst the observer rests the palm of his left hand upon the patient's thigh, he strikes with some implement held in the right hand several blows upon the ligamentum patellæ at about an eighth of an inch or so below the knee-cap. I nearly always employ for this purpose an ebony stethoscope, with a very heavy ear-piece and an india-rubber cord-like ring sunk into a groove on its margin. The quadriceps muscle can be felt, and (if the patient is in masculine garments) can be seen to contract more or less vigorously in response. If it be desired to ascertain the mere presence of the "reflex," this is sufficient. If, however, the response is very small, or is doubtful, or does not occur at all, the thigh as well as the leg must be bared, and other measures adopted, before a conclusion is arrived at. The leg should be crossed over the other, or the patient should be made to sit upon a table with his leg dangling. In either of these positions the presence of the "reflex" will be shown by the foot being jerked more or less vigorously forwards when the ligamentum patellæ is struck. In the case of a patient undressed, and lying on a bed, the knee should

be flexed, and the heel held firmly down upon the bedding whilst the blow is given on the ligament. The contraction of the quadriceps is readily seen.

Supposing that careful examination has established the absence of the phenomenon, we should next endeavour to ascertain at what point in the arc of nervous communication the break occurs by which the process is interrupted. Fig. 1 shows the normal condition, as it may be supposed

FIG. 1.

to be if the phenomenon be reflex. Impulses started by a blow on the tendon after traversing the afferent nerve, enter the cord in the posterior root, *pr*, and reach the anterior horn, *a h*, where they give rise to efferent impulses, which arrive by the anterior root, *a r*, at the muscle, and cause it to contract. From the tendon to the anterior horn is the sensory portion of the arc, whilst the motor part includes the anterior horn, anterior root, and intra-muscular nerve. The integrity of this nervous arc ensures the response of the muscle (provided the muscle itself be healthy) to a blow on its tendon. So also the fact that the quadriceps is found to contract freely when the ligamentum patellæ has been struck *almost always* signifies that the nervous arc is nowhere seriously interrupted in that part of the spinal cord which gives origin to the lumbar plexus. It is not, however, quite conclusive on this score, for a reason to which I shall refer later. If, on the other hand, careful testing shows the phenomenon to be absent, it is evident that there is a "fault" (as the miners say) or break at some point or other in the continuity of the nervous arc pictured in the diagram. Should the patient who presents this abnormality be walking freely about, and able to flex and extend his knee-joint with vigour, we may at once absolve the *motor* portion of the nervous arc from the suspicion of being the seat of interruption. Were it otherwise, and the break dependent on lesion in this direction, the "fault" must necessarily be either in the muscle itself (as, for example, from pseudo-hypertrophic paralysis), in which case there would be a very evident enfeeblement, or else either from lesion of the anterior root of the spinal nerve or atrophy of the large ganglion cells in the anterior horn. In each of these latter conditions there would be not only more or less muscular powerlessness, but also a considerable amount of muscular atrophy.

But the patient may have kept his bed for some time, and is weak and more or less emaciated. In this case it becomes necessary to resort to other expedients to ascertain the integrity of the motor part of the arc. If the knee-joint be capable of voluntary flexion and extension with a fair amount of force, it will be sufficient to percuss with some instrument the vastus internus where it projects just above and to the inner side of the knee-joint. This may be done with the thin ear-piece of an ordinary stethoscope.² If this blow, in these circumstances, excites a wave of muscular contraction, it may be taken as corroborative evidence that the muscle, motor nerve, and anterior horn are free from lesion. Should, however, there be a very powerless state of the limb, the occurrence of a wave of contraction in response to a blow

¹ The literature of the subject has rapidly become extensive, and includes, besides the work of Westphal and Erb, to whom is due the credit of inauguration, most important contributions by Tschirjew, Grainger Stewart, Gowers, Hughlings Jackson, Bramwell, Charcot, Brissaud, and Berger, amongst many others. There is an able article by Dr. Augustus Waller in *Brain*, Part X., in which the physiological side of the question is discussed, and the objections to the theory of reflex action are very forcibly put.

² Hawksley has made for me an ebony stethoscope, provided with a thick and also a thin ear-piece, which are interchangeable. The former is for percussing the tendon, the latter being used for the muscular structure.

upon the muscular structure of the vastus internus will not be sufficient to prove the integrity of these structures. I have found—and I do not think this fact is generally known—that a muscle which is cut off from its trophic centre either by lesion of a spinal nerve or atrophy of ganglion cells in the anterior horn of the cord, and which fails to contract to the strongest induced currents, will yet (provided it has not lost also the power of contracting to a slowly interrupted voltaic current—the reaction of degeneration) respond by a very palpable wave of contraction to blows upon it. So that if you strike a muscle and get a wave of contraction, all that you can predicate of it is this, that the muscle will respond to *some form* of electric excitation, not that it will necessarily respond to faradism. A muscle which thus responds to a blow may be perfectly normal, or, on the other hand, it may be far advanced towards a state of irreparable degeneration. In the latter case, however, the necessarily powerless condition of the muscle secures you from error.

It must be remembered that the patellar tendon-reflex is lost somewhat easily, and as the result of a small amount of structural change. It will often be found wanting when there is but a slight lowering of faradaic excitability. It is best therefore, whenever there is the slightest doubt about the matter, to test very carefully by induced currents the reaction of the vastus internus, the rheophore being applied to its motor point. The importance of this is evident. If by any want of care in examination we jump hastily and erroneously to the conclusion that the motor side is not in fault, we are driven to the necessity of ascribing the break to a lesion on the sensory side, and the diagnosis is consequently ruined.

We will consider that no such want of care has been shown, and that the examination excludes the muscle, motor nerve, and anterior horn of grey matter from being the cause of the break in communication. We have now to fall back upon the grey matter of the posterior horn, the posterior root zone, and the posterior root. In one or other of these structures the "fault" must lie. Cases in which the patellar tendon-reflex is absent in health are so extremely rare that this possibility may practically be disregarded—at least until every other explanation has been exhausted.

Through the kindness of my colleague, Dr. Ramskill, I am able to refer to a case of extreme interest bearing upon this point. The patient is a young man who is affected with loss of power in the left lower extremity. There is no loss of sensibility, but very extensive wasting of the muscles of this thigh, and their excitability by induced currents is lowered. The right lower extremity is free from paralysis or wasting; he can flex and extend it vigorously, and the muscles respond normally to faradaic currents. In this limb, however, there is cutaneous anæsthesia to a very marked extent. He presents, therefore, a typical example of Brown-Séquard's hemi-paraplegia. There is a lesion, which circumstances show to be probably syphilitic, occupying more or less definitely the left half of the spinal cord in the lumbar region, and giving rise to motor paralysis on the side of the lesion, and anæsthesia on the opposite side. The occurrence of anæsthesia, in these circumstances, in the limb opposite to the lesion was explained by Dr. Brown-Séquard, it will be remembered, by the fact that the conductors of sensitive impressions from the trunk and limbs decussate in the spinal cord, so that an injury or disease of the left side of the cord—e.g., affects the conductors from the right side of the body below. Now in this patient the patellar tendon-reflex is absent in each leg, not only in the left, which is paralysed and greatly wasted, but in the right also, in which the motor power is intact, but the skin anæsthetic. To explain its absence from the left (paralysed) limb it is evident that the "fault" must be in the anterior horn of the left side of the cord, in the motor portion of the nervous arc. In the right limb, on the other hand, it is lost in connexion with lesion of some part of the sensory tract, the exact situation of which it is not easy to indicate. It seems probable that the lesion of the cord (myelitis), although greatly confined to one segment, is not absolutely so, but, whilst sparing the right anterior horn, encroaches to some extent upon the right posterior horn, and "cuts" the communication at this point. The case is a most interesting example of the fact that the absence of the knee phenomenon may be due to lesion in either the motor or the sensory portion of the nervous arc, both modes being exhibited in one individual. In certain cases—as, e.g., where there is a

diffuse myelitis involving the whole transverse section of the cord—it may be due to both.

The most common and conspicuous illustration of a flaw on the *sensory* side destroying this reflex, is in the case of *tabes dorsalis*. Fig. 2 shows the position of the essential lesion in *tabes dorsalis* in the posterior root zone in that portion—i.e., of the posterior column adjacent to the posterior horn, which is largely composed of posterior (sensory) root-fibres making their way vertically to the grey matter above. Limitation of the lesion to this spot explains at once the almost constant connexion of lost reflex with the occurrence of lightning pains, whilst the integrity of the anterior horn and anterior root explains the fact that the quadriceps muscle is neither diminished in bulk

FIG. 2.

nor materially weakened as well as that it usually responds perfectly to faradaic currents, and also to blows upon its structure. In my earliest published reference to the subject of tendon-reflex, I remarked of a case of *tabes*,³ "The muscle is here, indeed, more than normally ready to contract upon direct local stimulation." Greatly extended experience since then has shown me that a condition of exceptional irritability to percussion is very common, perhaps indeed more frequent than not in *tabes*. Erb has since recorded a similar observation.⁴ He writes, "In striking contrast to the loss of tendon-reflex, the mechanical irritability of the quadriceps is always completely preserved, and is frequently even very pronounced and lively." I showed the other day that in an elderly man with typical *tabes* in whom there remained not a vestige of tendon-reflex, the irritability to direct percussion of the vastus internus far exceeded that exhibited in the ward attendant, a young and healthy man with a powerful muscular system. An explanation of this increased excitability is probably to be found in the irritative lesion of the posterior root-fibres, the cause of the lightning pains. The symptom must be classed indeed, I submit, in the same category with the tendency to cramp in sciatica, and the clonic spasm of facial muscles which is so apt to occur in severe trigeminal neuralgia.

It occurred to me a few days ago to examine in reference to this subject a patient whose supra- and infra-orbital nerves have been recently stretched for severe neuralgia of the two upper divisions of the trigeminus on the right side. The patient was for a time greatly relieved, but is subject to occasional paroxysms of pain, and there yet remains a considerable amount of clonic spasm of the muscles on that side of the face. There is manifestly an abnormally irritable condition of the muscular tissue. This irritability, however, does not extend to the tendons. Repeated testing by percussion showed that the contraction of the zygomaticus major of the *left* (sound) side of the face, which followed a blow upon its tendinous origin on the malar bone, was distinctly much more energetic than that of the corresponding muscle on the *right* (affected) side. My reason for selecting this case for observation on this point was as follows. As is well known, the sensory supply to the face is derived from the trigeminus, the motor influence from the portio dura. Now, the sensory portion of the fifth is acknowledged to represent the posterior root of a spinal nerve. There had therefore been in the operation of stretching a kind of vivisection (with a therapeutical, not a physiological, object, as it happened) performed upon what is practically the posterior root of the nerve supply to the muscles of the face. In no other part of the body could the operation have been so limited to this effect; in the spinal nerves the posterior and anterior roots are united in one trunk. Now, supposing that nerve-fibres from the tendon take their course to the centre in the posterior root, as Tschirjew has stated, I ought to find, it appeared to me, the response to stimulation of tendinous fibres on the side on which the "posterior root" had been stretched, and therefore injured, less active than on the sound side. I had some difficulty in selecting a muscle

³ THE LANCET, July and August, 1878.

⁴ Zur Pathologie der *Tabes dorsalis*, Deutsch. Arch. f. klin. Medicin, Marz, 1879.

upon which the experiment could be tried, but the zygomaticus major showed it very well, although on a necessarily small scale. It is of no small interest to observe that although the muscular tissue was generally over-irritable (like the muscle in tabes) the response to a tap on the tendon was distinctly less vigorous than that on the sound side. I do not wish, however, to draw positive conclusions from a single observation of this kind. It would be well to repeat the examination in a patient affected with a destructive lesion of the fifth nerve, or in whom the infra-orbital trunk had been divided for neuralgia.

(To be concluded.)

ON CHIAN TURPENTINE AND ITS USELESSNESS IN CANCER.

By HENRY MORRIS, M.A., M.B.,

SURGEON, AND SURGEON TO THE CANCER OUT-PATIENT DEPARTMENT, OF THE MIDDLESEX HOSPITAL.

In his second article "On Chian Turpentine and its Use in Cancer" (in THE LANCET, Oct. 2nd, 1880), Prof. Clay says, "Certain results obtained by the use of a remedy almost forgotten by the therapist, were placed by me unreservedly before the profession; and for the benefit of suffering humanity, at least, a fair trial of the remedy ought to be given before condemning it."

With what willingness a fair trial of this drug was entered upon and perseveringly continued at the Middlesex Hospital, and with what gladness we would have welcomed any measure of success with it, will be very readily believed by all who have to follow cases of cancer along their melancholy course to their tragical end. Moreover, the large opportunities for watching cancer of all kinds afforded by a hospital which, besides receiving cases of cancer for operation into its general wards, has a special cancer out-patient department open to all comers, and thirty-two specially endowed beds, which may be retained until the occupants are "relieved by art or released by death"; the tradition which makes it an essential part of the duty of the surgeons of the Middlesex Hospital to do whatever within them lies for the relief or cure of cancer; together with a large share in the universal desire that a remedy for this frightful, and frightfully common, malady may be discovered—naturally incline us to test the value of anything which seems to offer even the faintest ray of hope. Perhaps, however, it must be admitted that past experience of acetic acid, bromine, condurango root, and various other external and internal methods of treatment, deprives us, at the outset, of that enthusiasm of great expectations which some might possibly indulge.

But besides testing remedies, it is also expected that we duly lay before the profession the results, and it is on this account that I publish brief notes of the following cases.

In answer to those who have hitherto questioned the efficacy of Chian turpentine, Professor Clay has replied: (1) That "in a large percentage of cases factitious turpentine only has been used in the treatment of cancer"; (2) that a sufficient time has not been allowed to elapse for the full effects of the remedy to be manifested; and (3) that the full effects of the pure turpentine have not been gained in some instances because, owing to its incomplete compounding, the drug has not been entirely digested.

It is therefore necessary that I should state: (1) That the turpentine used in the following cases was at first some which was in stock at the hospital, and answered thoroughly to the descriptions of the genuine, pure turpentine. When this was exhausted, more was obtained from two well-known houses, and it was a sample of one of these which was publicly condemned by Professor Clay. Owing to the Professor's letter to the *Med. Times and Gazette* (May 15th), the use of these was at once stopped, and another supply was obtained, at his recommendation, from the Apothecaries' Company. Lastly, in the first week of October I commenced to use some placed at my disposal by a

friend, to whom it had been sent by Professor Clay. It is this which I am still using, and have been doing ever since I received it. (2) As regards the length of time the drug has been administered, I can only say that in several of the cases, if the time has been insufficient, it has not been my fault or that of the patient, but is due to the fact that the disease continued to run its course, uninterrupted by the drug, to its fatal end. (3) Both the pills and the mixture have been made in strict accordance with Professor Clay's directions by Mr. Challice, our skilful dispenser, who had, prior to Professor Clay's last article, pointed out the way to avoid any separation of the resin.¹

Professor Clay's confidence in the remedy having increased, he says he is justified "in stating that uterine cancer at least may be removed by the use of Chian turpentine;" and adds: "Most of the cases of cancer which have presented themselves are in an advanced stage of the disease, and more especially is this the case in cancers of the uterus. Yet the treatment continues to be very efficient." He has, too, put on record marvellous benefit accruing to four of his patients in such a very short time as four days, seven days, fourteen days, and sixteen days respectively, and has besides given one admirable result in a woman who, four months before, had been told at the Middlesex Hospital that "her case was incurable and that she had not long to live,"² but who after undertaking the journey to Birmingham became an in-patient at the Queen's Hospital, and was so much improved by the Chian turpentine treatment that in nine weeks she was "about to return to London with every prospect of soon being cured." None of the following cases, therefore, are open to objection on the ground that the disease was too far advanced when the turpentine was commenced; nor can the genuineness of the drug, or its method of administration, be fairly called in question.

CASE 1. Carcinoma of the fundus of the uterus; destruction of the whole organ; death.—Ann H—, aged sixty, a cook, was admitted into Stafford ward on February 2nd, 1880. Single, and had never borne a child. General health always good, except that she had suffered greatly at her menstrual periods. Catamenia commenced before the sixteenth year, had always been scanty, and ceased altogether at fifty. No cancer in family. At the beginning of January, 1879, she began to feel very weak and unequal to her work. In August, 1879, bearing-down pain in the vagina commenced; and intense hæmorrhage, which had occurred once or twice previously, now became worse. Was treated at the Great Northern Hospital in September, 1879; since then the hæmorrhage has ceased; but soon afterwards an offensive whitish discharge commenced.

On admission she was fairly nourished, but pale looking; was cheerful in manner; but said she had lost flesh, as she was at one time very stout. Suffered greatly from dragging pain in the pelvis, and had a thick, offensive leucorrhœal discharge.

Vaginal examination.—There is no ulceration of the vagina or of the os or cervix of the uterus, but an indurated and uneven enlargement of the fundus.

Sedatives, with tonic and laxative medicines, were administered during February, March, and part of April; but on April 16th Chian turpentine, in the form of mixture, was commenced, and taken three times a day without interruption until the beginning of August, when it was omitted for a time on account of sickness.—May 4th: the pain complained of is severe and frequent, more especially after sitting up. Getting out of bed is followed by hours of severe pain. Discharge considerable and blood-stained.—May 11th: The discharge is sometimes quite black; it has increased the last eight or nine days, but is not so offensive.—May 21st: Pain still continues severe; takes opium or morphia twice daily, to relieve the pain over which the Chian turpentine mixture seems to have no influence.—June 25th: Still no ulceration to be felt per vaginam, but there is considerable and painful œdema of the genitals.

During September the Chian turpentine mixture was again taken, but irregularly, and only as it could be tolerated by the stomach. On Oct. 2nd it was again commenced to be taken regularly three times a day, and was so continued

¹ Vide *Pharmaceutical Journal*, June 26th, 1880.

² Professor Clay having courteously informed me of the name of this patient, I asked Mr. Fardon, the resident medical officer, to refer to her case, but though he has searched both the in- and out-door cancer registers for two years, and the obstetric registers for the last year, her name does not appear. As Professor Clay adds, the statements of patients are not always to be relied upon. It seems more than probable that in this instance he was misinformed.

up to the date of death.—Sept. 27th: The posterior portion of the cervix thickened and ulcerated; vagina intact; vaginal examination causes much pain, therefore the condition of the body of the uterus was not ascertained; bowels constipated; from this time the injurious effects of the disease very rapidly progressed, and she died on Nov. 7th.

Necropsy, by Dr. FOWLER, twenty-nine hours after death.—Body emaciated. Abdomen retracted. The uterus, with the exception of the os, and small part of the cervix, had entirely disappeared, and in its place there was a sloughy cavity containing faecal matter. One of the adjacent and adherent coils of intestine had ulcerated through where it had formerly formed an adhesion with the uterus. The vagina was scarcely affected; the mesenteric glands were enlarged from cancerous deposit. On the posterior surface of the lower lobe of the right lung there was a small cancerous nodule the size of a pea. On the surface of the right kidney there was a small spot, probably a commencing secondary deposit of cancer. The kidneys were otherwise healthy.

Remarks.—In this case it will be noticed that the turpentine treatment was continued uninterruptedly for three months and a half, then omitted for about three weeks, and then taken irregularly, but mostly once or twice a day, for another two or three weeks, when it was again administered regularly three times a day for another five weeks. It should be added of this patient that she was very docile and intelligent, and entered readily into the trial of the effects of the drug upon her. She even willingly consented to forego the anodynes (opium, morphia, and belladonna) which were given internally and applied externally to relieve her great sufferings; but after a fair trial of the anodyne effect of the turpentine, I felt that it was cruel, notwithstanding her willingness, any longer to withhold the other drugs, as she suffered so much more severely when not under their influence.

CASE 2. Carcinoma of vagina, clitoris, urethra, and external genitals; death.—Mary H—, aged fifty-five, was admitted into Stafford ward on Feb. 12th, 1880. A married woman, mother of six children, the youngest of whom was twenty-one years, and the eldest thirty-one years; no miscarriages. Her catamenia appeared at twelve; had always been regular and painless till the present time; general health always excellent. No family history of cancer. For the last two or three years has had a "weakness about the womb," with some offensive discharge, but without hæmorrhage or pain. Has lately been treated for a few weeks as an out-patient at two different London hospitals; has not been losing flesh, nor has she felt ill, though she has not been equal to much work of late.

On admission she was a stout woman, with rather relaxed, flabby tissues, somewhat anæmic, but not cachectic.

Vaginal examination.—The posterior wall of the vagina and the os and cervix uteri are normal. Immediately behind the anterior fourchette of the vulva, and extending backwards from this so as to involve the clitoris, urethral orifice, and floor of the urethra, together with the corresponding surface of the vagina, is a nodular, ulcerated, and indurated tract, projecting both into the vagina and forwards towards the bladder, and extending more on the right than on the left side. Above this is an area of healthy vaginal wall. In the left iliac region the glands are enlarged. Has incontinence of urine, but not much discharge.—April 2nd: The lower wall of the urethra is destroyed by ulceration; the base of the bladder bulges against the anterior wall of the vagina immediately beyond the ulcer; complains of much scalding pain. Chian turpentine in pills commenced to-day; all other remedies discontinued. On May 11th there was no relief from the pain; the discharge was profuse, and of a very offensive odour. Morphia was now required twice a day. On May 18th the turpentine pills were replaced by the turpentine mixture. She died rather suddenly on May 20th, suffering greatly to the end.

Necropsy, by Mr. LYELL, twenty-two hours after death.—Body very well nourished. A large quantity of fat subcutaneously, and throughout the body generally. Externally, part of the genitalia had been destroyed by cancerous ulceration; the clitoris, orifice of the urethra, and parts around this having disappeared. On removing the pelvic organs, the knife in front entered the cavity of the bladder, the front wall of which was adherent to the back of the symphysis pubis. The greater part of the front wall of the vagina had disappeared, together with the whole of the urethra, so that

the bladder opened into a cloaca formed by the remainder of the vagina. The mucous membrane of the back of the vagina was in places roughened from deposits of a soft mortuary, phosphatic nature. The base of the bladder and what remained of the anterior wall of the vagina were infiltrated with whitish, firm, cancerous material, which also completely infiltrated the surroundings of the bladder at its lower part. When the bladder was laid open along its anterior surface, it was seen that the mucous membrane around the ulceration was covered with a mortuary, phosphatic deposit about an inch and a quarter wide. Above this the mucous membrane was of a dark-red colour, and speckled all over with small adherent phosphatic deposits. The uterus weighed twelve ounces; the cervix was natural, but the body was much enlarged, and contained four intramural fibromata about the size of walnuts. Rectum normal and partially empty. The kidneys were granular, with adherent capsules and diminished cortex; the right contained a small superficial cyst; the pelvis of neither was altered. The abdomen contained no fluid or evidence of recent inflammation. There was a slight excess of the quantity of fluid generally found in the ventricles of the brain.

Remarks.—It will be noticed that in this case a large vesico-vaginal fistula existed. Though the kidneys were granular, it is specially mentioned in the post-mortem report that the conditions due to obstruction of the ureters were not present. Professor Clay states that when the anterior wall of the vagina is involved the case is not so suitable for the treatment, and the turpentine is not well tolerated; "but when a fistula forms it is better borne."

CASE 3. Cancer of the uterus; death.—Emma T—, aged twenty-eight, was admitted to Stafford ward, March 4th, 1880. Married, and had five children in five years. Catamenia first appeared at fifteen, and continued regular until October, 1879. General health always good till fourteen months before admission. No cancerous history. Has never been well since the birth of her last child in December, 1878, since which she has had a continuous yellow discharge, has never menstruated, and has suffered severe pain in the abdomen. Has never flooded.

On admission the vagina was intact, the uterus movable, fundus enlarged, os and greater portion of cervix disappeared. What remained of the cervix was greatly indurated, much thickened, and very irregular. Above the line of ulceration there were a few shot-like nodules. Discharge offensive.—April 2nd: Complained of great pain in the left side of the abdomen, and for the last three or four days had been losing a little blood. There was the same hard ulcerated condition of the cervix; the edges of the ulcer were everted. Chian turpentine in pills was commenced; to be given twice a day, all other remedies being discontinued.—4th: Feels decidedly better; has much less pain, but still a little hæmorrhage.—6th: The Chian turpentine pills discontinued, and the mixture given three times a day instead. Pain to-day is as bad as ever, and is of a twisting character; has had less hæmorrhage.—13th: Pain varies slightly from time to time, but on the whole is much less. The discharge is not so great, but is more offensive now than formerly.—27th: Is suffering from indigestion and morning sickness. The uterine discharge is less.—May 4th: Chian turpentine discontinued, and a mixture of bismuth and calumba given instead.—11th: Has been taking the turpentine mixture again for the last three days. There is no difference in her condition.—25th: Has been getting gradually worse since last note. The discharge is greater in quantity, offensive in character, and of a browner colour. The uterus is very painful and tender to the touch. Her mouth is parched; she has a great craving for liquids. Subsequently she had a mild attack of pericarditis, from which she rallied.—June 4th: She had very severe hæmorrhage, which was not stopped until the vagina was plugged. The Chian turpentine discontinued to-day, and tincture of ergot given. She died on June 7th from exhaustion. No post-mortem allowed.

CASE 4. Cancer of the uterus and vagina.—Charlotte W—, aged fifty-five, applied to the cancer out-patient department of the Middlesex Hospital on March 4th, 1880, suffering from cancer of the uterus and vagina in an early stage. She was married and the mother of three children. Until April 1st she was treated with quinine and iron mixture, and Condy's fluid as an injection. Chian turpentine in pills was now ordered.—April 8th: She said that she was sure she was better for the pills, having had no

hæmorrhage, less watery discharge, and less pain.—July 1st: Seen again to-day, as she is not so well. She has not attended before since the last note was made, as she had been feeling better; but the pills given her on April 8th could not be retained, as she retched so much after them. She was now ordered to try the mixture, but she would not persevere with it.

Remarks.—This case is purposely included, not because it shows the effects of Chian turpentine, but because it is an example of a class of patients very likely to excite false hopes as to the result of the treatment. After taking a tonic for three weeks, and the turpentine for a week, and using a cleansing injection the whole time, the local symptoms were relieved. As her general health had not yet become affected by the disease she was sufficiently well satisfied with her improvement to leave off all treatment for some months. Had she been taking the turpentine several weeks, one might perhaps have supposed, from her own account and her long absence, that she had been cured by it.

(To be concluded.)

CLINICAL REMARKS TO STUDENTS

ON THE

DIAGNOSIS OF THE VARIOUS FORMS OF CONGENITAL HEART DISEASE.

By SEYMOUR J. SHARKEY, M.B.,
ASSISTANT-PHYSICIAN TO ST. THOMAS'S HOSPITAL.

GENTLEMEN,—You cannot have failed to notice that we have seen in the out-patient room during the last six months an unusually large number of patients suffering from congenital diseases of the heart; and it must also have struck you that the information I gave you regarding them was singularly vague and unsatisfactory. When patients have presented themselves suffering from heart disease which they have acquired since birth, owing to attacks of rheumatism or lesions dependent upon other causes, our diagnosis of the particular valve affected, and of the conditions of the several cavities of the heart, has been given with a considerable degree of confidence. But in cases of congenital disease assertions have given way to suggestions; and I have usually bluntly acknowledged that I could not say what the position or nature of the lesion was. And this I have done, and still do, without the least appearance and actually without the least sense of shame. For the bold confession of ignorance is better than the assumption of a wisdom to which we may aspire, but which we certainly have not yet attained.

The actual pathological condition of the heart, when the seat of congenital disease, is less frequently diagnosed by the bedside than the pathological condition of any other organ, with, perhaps, one exception—the all-but-immaculate pancreas. It is rarely that a physician ventures to breathe so much as a word of suspicion against the integrity of this organ, which, while well known to play a most important part in digestion, seems to enjoy a remarkable immunity from disease. The reputation for innocence which the pancreas has obtained is, however, well earned. For pathology, in spite of its efforts, records but few well-founded accusations against it. In the case of the heart, on the contrary, medical literature abounds in a variety of the most fatal lesions, with which children are afflicted from their very birth; and notwithstanding this, the cases in which a physician is able to state what the disease or malformation is are exceedingly rare. What I wish to explain to you now is, why our endeavours in this direction are so fruitless. Let me refresh your memories by alluding briefly to some points in connexion with the development of the heart, for you will find that a right appreciation of the abnormal conditions which it presents at birth depends altogether on a knowledge of its intra-uterine history. The heart at one time consists of a mere tube, which doubles upon itself, receiving at one extremity two veins—the omphalo-mesenteric veins,—which come from the yolk-sac, and giving origin at the other to a large arterial trunk, the bulbus arteriosus. The latter divides into two

arches, a right and a left, which are the primitive aortæ, and these again unite into a single trunk in the body of the embryo. It is unnecessary for our purpose to follow the development of the pulmonary artery, aorta, and vascular supply of the upper extremities and head from the vessels which run in connexion with the visceral arches, or to trace out in detail the gradual formation of the venous system; but it is necessary to state that the heart, which originally consists of two cavities separated from each other by a constriction, is gradually divided into four. This is effected by the growth of two septa, one dividing that part of the organ which receives the veins into two primitive auricles, and the other dividing that part from which the arterial trunk arises into two ventricles. A partition and valves, which are the auriculo-ventricular valves, also separate the auricular from the ventricular portion of the heart. The auricular and ventricular septa are of gradual growth. The latter grows from below upwards and forwards, and leaves for some time an aperture of communication between the two ventricles. The auricular septum grows from before backwards, but up to the period of birth it is perforated by a valved orifice—the foramen ovale. These defects in the septa, the foramen ovale, or other larger communication between the auricles, on the one hand, and the aperture between the ventricles on the other, are of special importance in pathology; and I wish to call your particular attention to them, as they figure largely in congenital diseases of the heart. The normal condition of the circulation just before birth is roughly this: The blood coming from the body generally, and from the placenta by the great veins, enters the right auricle; part is directed by the Eustachian valve through the foramen ovale into the left auricle, part goes into the right ventricle. A small portion only of the latter is conducted by the pulmonary artery to the still inactive lungs; while the rest is propelled by a short cut, the ductus arteriosus, into the aorta, and reaches the placenta and lower parts of the body. At this period, therefore, the right ventricle carries on the principal part of the systemic circulation. The blood from the lungs returns to the left auricle, and there meeting the stream which has come through the open foramen ovale from the right auricle, passes on into the left ventricle and aorta, and supplies the head and upper extremities, a small portion passing onwards to join the stream from the ductus arteriosus in its journey to the lower parts of the body. The whole mass of blood then returns from the upper and lower parts of the fetus to the right auricle (from which our description started), and commences the circle anew.

It will be seen that the foramen ovale and ductus arteriosus are nothing more than short cuts, by which the blood reaches the general circulation without having to go through the lungs, which are at this time almost impervious. The changes in the heart, which occur at birth, mainly have reference to these two structures; for on the sudden expansion of the lungs with the first inspiration, the blood is drawn into them, and gradually ceases to go through the contracting ductus arteriosus. It then returns in a full stream from the lungs to the left auricle, and closes the valve of the foramen ovale. The closure of the ductus arteriosus and foramen of ovale takes place during the first month of extra-uterine life, and the circulation is then such as we find it in the adult.

Congenital diseases of the heart have their origin either in arrest of development or malformation of some part of the organ, or else in inflammation of its growing structures, or, perhaps, still more commonly in a combination of these two causes. For instance, some cases consist in simple patency of the foramen ovale, without other detectable abnormality. Such an arrest of development may allow the venous blood in the right auricle to mingle with the arterialed blood in the left without passing through the lungs. When students have a case of congenital disease of the heart pointed out to them for the first time, they almost always ask whether it is a case of “patent foramen ovale.” But patency of the foramen ovale, pure and simple, is of extreme rarity. It is true that this orifice very often remains open in congenital diseases, but such a condition is almost always secondary to some disease of the valves or other structures, and so far from adding to the gravity of such cases, it is often absolutely necessary for the continuance of the circulation at all. If, for instance, there is an obstruction which prevents the blood from going in sufficient quantity through the pulmonary artery, some passage such as the foramen ovale must remain open to allow the blood to reach the left side of

the heart; and if no such passage exist, the child cannot live.

Much more frequent than these simple orifices in the septa of the heart are those cases where there is some stenosis of valve or vessel, produced by inflammation or by malformation of the part. All such lesions occur infinitely more frequently on the right side of the fetal heart, while those which arise after birth are almost confined to the left. Consider what must happen if a child is to live, in whom either the pulmonary artery or the right auriculo-ventricular orifice is partially or entirely obliterated. To reach the aorta the blood on the right side must by some means make its way to the left side of the heart; and as it is prevented from flowing onwards through the pulmonary artery, it finds a passage in the direction of least resistance, through the incomplete auricular or ventricular septum, and so—fortunately for the life of the child—prevents these apertures from closing. But while the natural thoroughfare for the venous current to the lungs is thus blocked, and the stream conducted in another channel, it is essential that some device should be found whereby a sufficient quantity of the circulating fluid may be exposed to the air in the respiratory organs. To reach the pulmonary artery the blood sometimes travels along the aorta into the ductus arteriosus—which, as you know, connects these two great vessels,—and so on into the lungs. Hence it is that the ductus arteriosus may be kept open in such cases, and the bronchial or œsophageal arteries may also enlarge and assist in the pulmonary circulation. Sometimes, however, no such collateral circulation being set up, the patient has to carry on the vital processes on the small quantity of oxygen which can be taken up by a feeble stream of blood driven through a contracted orifice.

In those rarer cases where there is some obstruction on the left side of the heart, which prevents a sufficient quantity of blood from passing into the aorta, the pressure of the fluid stagnating on the left causes a stream to flow through some aperture in the septa into the right side, from whence it may be carried by the pulmonary artery not only to the lungs, but also through the ductus arteriosus into the descending aorta, the right ventricle then carrying on, as it does in the fœtus, a great part of the systemic circulation.

The ordinary clinical cases of congenital disease of the heart depend thus on an obstruction of some orifice or vessel and a patency of some of the fetal communications by means of which the blood gets to parts beyond the obstruction. In some of these cases it is possible that the patency of the fetal opening may be due to an arrest of development, and be the primary event, while the contraction of the vessel, owing to diminution of blood-pressure in it, is the secondary; but if so, the clinical result remains the same.

The object of the complete separation of the cavities of the heart in the adult is, that all the blood may go through the lungs and be arterIALIZED before reaching the general circulation. Congenital diseases usually entail a mixture of the venous and arterial blood, which is one factor in the production of the typical cyanosis in these cases. The septum ventriculorum is completed somewhere about the third month of fetal life; and therefore if any disease arise after that time the foramen ovale or some larger defect in the auricular septum must be the passage of communication between the two sides of the heart. If the disease occur earlier than the third month, then the ventricular septum may remain open, either alone or in addition to the foramen ovale. Hence it is that the condition of the heart in the patient will vary according to the time at which the disease or malformation occurred.

(To be concluded.)

ON CATARRH OF THE STOMACH IN CHILDREN.

By EUSTACE SMITH, M.D., F.R.C.P.,

PHYSICIAN TO H.M. THE KING OF THE BELGIANS, PHYSICIAN TO THE EAST LONDON CHILDREN'S HOSPITAL AND TO THE VICTORIA PARK HOSPITAL FOR DISEASES OF THE CHEST.

(Concluded from page 806.)

THE febrile form of gastric catarrh, although far from being rare, is yet much less common than the non-febrile variety. Catarrh of the stomach, unaccompanied by fever, is perhaps the commonest derangement to which children are exposed. It is a constant danger to hand-fed babies, and

forms, indeed, the chief obstacle to the successful rearing of infants. Even in the case of older children, if of frequent occurrence, it may seriously affect nutrition, and interfere with development and growth. Most children suffer at times from what is called "biliousness." For two or three days together they lose their appetite; mope and lie about; have a dull, pasty, or sallow complexion, and look dark under the eyes. At night they sleep badly, and they are restless and irritable in the day. These symptoms are produced by a temporary catarrh of the stomach, which interferes for the time with the digestion of food, but, passing off, leaves no ill consequences behind. When, however, the attacks are frequent, digestion is weak even in the intervals of comparative health, and nutrition becomes seriously impaired. Such children complain often of flatulent pains in the sides, and may be subject to attacks of syncope from pressure upwards of the distended stomach against the heart. Their bowels are usually costive.

These symptoms may be greatly aggravated by an injudicious dietary. If a child who suffers from the condition described be supplied with an excess of fermentable food, such as potatoes, puddings, jams, and sweet cakes, he is kept in a state of chronic acid dyspepsia, which is a source of constant discomfort to himself and anxiety to his friends. The whole system being full of acid, generated by fermenting food, the child is wayward and cross in temper, and excessively fidgety and restless. His speech is often hesitating, and he may stammer in his talk. His muscles are irritable and twitch easily, so that he winks his eyes and distorts in nervous fashion the corners of his mouth. The so-called nervous habits of children often owe their origin to this derangement.

Sickness is not a common symptom in these cases, for gastric catarrh is by no means always accompanied by irritability of stomach. Sometimes, however, the child at rare intervals brings up a large quantity of sour-smelling fluid and mucus. Frontal headache, more or less severe, is rarely absent, and oftentimes the pain is very distressing. The wearing periodical headaches of children are usually owing to this cause. The urine is from time to time noticed to be thick with lithates, and, in rare cases, quantities of fine uric-acid sand are passed, precipitated by the free acid with which the urine is charged. At such times the urine may contain a trace of albumen.

Symptoms such as the above show a high degree of digestive derangement, aggravated by an unsuitable dietary, and are almost invariably the consequence of repeated attacks of catarrh of the stomach. Under such circumstances nutrition is interfered with, the child wastes perceptibly, and the apprehensions of the parents are carried to a high degree. When, on the other hand, the indisposition is only occasional, and the symptoms are not severe, little attention is excited. The child is supposed to be a "bilious" subject, and unless the attacks become so frequent as to cause an evident diminution in bulk, or some new symptom is noticed which excites the alarm of the friends, medical advice is considered unnecessary.

In cases where, owing to the mildness or the infrequency of the attacks of gastric development, general nutrition has not suffered, the occurrence of fainting-fits may induce the parents to apply for medical assistance. Attacks of syncope, more or less complete, are not uncommon in these cases. They, naturally enough, give rise to great anxiety; especially if conjoined with palpitations and flatulent pains about the chest. They are then considered to be symptomatic of heart disease. Thus:—"Miss W—, aged eleven years and a half, fainted for the first time six years ago. She has since fainted on five different occasions. At these times she has always been noticed to be dull and languid, with a poor appetite, but otherwise has seemed to be well. Is subject to sharp pains in the left hypochondrium, under the influence of which her face will become ghastly white. She sleeps badly, talking and moaning, and often lies awake at night. Has never suffered from worms; bowels costive. Has sometimes a sallow complexion." This young lady, who was a well-grown, well-nourished girl, with perfectly sound organs, soon lost all her symptoms under suitable treatment.

Whether the gastric catarrh assume the febrile or the non-febrile form its treatment is the same. Our object is, firstly, to put a stop to the existing derangement, and, secondly, to adopt such measures as will prevent its recurrence.

To cure the existing catarrh we must do our best to remove all sources of irritation which may be keeping up the

disorder. The acrid mucus, a free secretion of which is one of the ordinary phenomena of the catarrhal state, is a constant cause of fermentation and acidity. It very quickly induces an acid change in the more fermentable articles of food. Therefore, if the stomach be oppressed by sour matters, shown by uneasiness at the epigastrium, or sour smell from the breath, and a feeling of nausea, immediate benefit will be derived from an emetic dose of ipecacuanha wine. Afterwards a draught, composed of tincture of nux vomica, with bicarbonate of soda, in water sweetened with spirits of chloroform, taken two or three times in the day, will soon restore the gastric mucous membrane to a healthy condition. Strong purgatives are to be avoided, but as there is usually constipation in these cases, an occasional mild aperient will be required, such as compound liquorice powder or castor oil. If there be fever, which does not subside after the action of the emetic, the child may be allowed to take fluids from time to time in moderate quantities. The best are unsweetened barley-water, flavoured, if desired, with orange-flower; toast-water, or fresh whey.

During the treatment, as long as any signs of acidity of stomach persist, care should be taken to exclude from the diet all matters capable of favouring the tendency to fermentation of food; and even for some time afterwards, readily fermentable substances, such as starches and sweets, should be taken sparingly, lest the derangement be encouraged to return. At first nothing should be allowed but freshly made broths, with dry toast; and when milk is once more permitted, it must be guarded with a fourth part of lime-water, or with saccharated solution of lime, in the proportion of twenty drops to the teacupful. While the derangement continues no fruit, cakes, sweets, light puddings, or potatoes should on any account be permitted to be taken. When the appetite begins to return, a little fish, chicken, or mutton may be allowed, but the child must not be pressed to eat; indeed, until its digestive power be completely restored, the utmost care must be taken not to overload the stomach with food.

The above measures will effect a considerable improvement in the condition of the child, but at this point the treatment may be said only to have begun. The patient is in a weakly state from successive attacks of gastric catarrh. We have, therefore, to adopt means to strengthen the digestive powers, and take such precautions as will ensure him against a relapse.

To give tone to the stomach and strengthen digestive power preparations of iron are required. A common practice in such cases is to administer the preparation of the phosphates of iron and lime known as "Parrish's Chemical Food." This syrup is a very favourite remedy with mothers, who, misled perhaps by the name, give it largely, and with the worst results. Theoretically, no doubt, it is an active tonic, but practically it is highly pernicious. The reason is that the syrup in which the phosphates are dissolved supplies materials for fermentation, and each dose is soon followed by flatulence and acidity; so that the medicine really aggravates the mischief which it is intended to allay. The better plan is to give the dialysed iron, or, if there be any tendency to acidity remaining, the ammonio-citrate, with a few grains of bicarbonate of soda, sweetened with aqua chloroformi. After a time a change may be made to the solution of strychnia, with the perchloride or pernitrate of iron, given directly after food. All this time the quantity of fermentable material taken at meals must be restricted, as already recommended. During the same time a mild aperient should be given every few days, whether it seem to be required or not, to ensure a proper relief to the bowels and prevent the retention of any excess of mucous secretion.

In spite of this treatment, however, the child will not be secure against relapses unless special precautions be taken to guard the body against chills. The catarrhal state, whatever be the organ affected, tends constantly to repeat itself under the influence of slight causes; and there is little doubt that it induces an extreme sensitiveness to changes of temperature. Children who suffer from attacks of catarrh of the stomach or bowels should wear a broad flannel binder applied tightly to the abdomen, so as to reach from the hips upwards to the armpits, and the medical practitioner should look upon it as his first duty in these cases to see that it is properly applied. The binder should be considered as part of the child's ordinary dress, and be cast off at night with the rest of his clothes. In many cases it is necessary, in addition to the above precautions, to fortify the resisting power of the child by cold bathing. Some circumlocution

is, however, often necessary in recommending this step to parents. Mothers are apt to take fright at the very mention of cold water; and it is true that in the case of weak children reaction is difficult to establish, so that a cold bath given in the ordinary way would not be attended with benefit. There is, however, a method by which the most delicate child may take a perfectly cold bath with safety and advantage. The method consists in first stimulating the skin by friction, so as to enable the body to resist the shock of the cold douche, and then in lessening the shock itself by placing the patient in hot water. Thus, if a child on rising from its bed be well shampooed over the whole body, but especially over the back and spine, and be then made to sit in a few inches of quite hot water, a good douche of cold salt water over the shoulders will have a highly invigorating effect, and be followed by immediate reaction. After being dried, the body may be rubbed with flesh gloves, and afterwards, if thought desirable, the child can be returned for a short time to his bed. Before beginning the process the patient should take a little bread-and-butter, or a drink of milk. The continued use of this bath, besides having a remarkably tonic effect upon the system generally, confers great resisting power against changes of temperature, and considerably reduces the child's susceptibility to chills.

By means such as have been indicated, the most obstinate cases of gastric catarrh may be treated with success. But it should be borne in mind that success depends upon equal attention to all the points which have been insisted upon. A flannel binder will be of little value if the tendency to fermentation be encouraged by the immoderate use of starches and sweets; and even cold douching may not be sufficient to neutralise the ill effects of rapid changes of temperature acting upon a body imperfectly protected from the cold. In all cases it is advisable to avoid the use of syrups in making medicines palatable to young children. The Pharmacopœia syrups are not well borne by young subjects, and often do more harm than good. It is far better to sweeten a child's physic with glycerine, or a few drops of spirits of chloroform.

George-street, Hanover-square, W.

CASE OF STRANGULATED FEMORAL HERNIA IN AN INSANE PATIENT.

OPERATION; PERITONITIS WITHOUT DEVIATION FROM
NORMAL PULSE AND TEMPERATURE; RECOVERY.

By S. A. K. STRAHAN, M.D.

W. S—, aged fifty-one years, was admitted into the East Riding Asylum on the 24th June, 1880, suffering from a first attack of insanity—melancholia with strong suicidal tendency. On admission he was found to have a large scrotal hernia (right) of long standing and a hydrocele of the left tunica vaginalis testis. He was very weak bodily—evidently the result of having partaken sparingly of food for some time previous, as he laboured under the delusion that there was no passage for food through his body.

For seven weeks after admission he partook of food in reasonable quantity, under protest; at the end of which time he refused all food, and had consequently to be fed twice or oftener daily by means of the stomach-pump. This feeding was continued up till Sept. 17th (four weeks), with a few intermissions of a day, or in some cases two days, when he ate reluctantly on the pump being ostensibly put in order.

Sept. 18th.—This evening he complained of abdominal pain, which he attributed to eating so largely. His abdomen was at once examined, when, in addition to the scrotal hernia already noticed, there was found a femoral hernia (left), about the size of a walnut, tense, painful, inelastic, and giving a dull note on percussion. Gentle taxis was applied without appreciable effect, and afterwards the following means for facilitating its reduction were tried without success—namely, warm bath, opiate, chloroform, and injection of water per rectum.

19th.—Symptoms of strangulation appeared to-day, six-

teen hours after the discovery of the hernia, and at 4 P.M. the operation for its relief was performed under chloroform by Dr. Whitcombe, medical superintendent. Gimbernat's ligament was the seat of stricture, but after this was divided, it was found necessary to open the sac, because of bands formed in its neck. All constrictions having been removed, the hernia—which consisted of about two inches of small intestine of a dark slate-colour, from strangulation—was returned to the abdominal cavity, the external wound brought together by means of three silk sutures, and a pad of dry lint and a bandage applied. Patient was then placed in bed and had one grain of opium, to be repeated every four hours; milk and brandy to be taken in small quantities.

20th.—Patient passed a good night, and was going on well till 5 o'clock this evening, when symptoms of peritonitis appeared—viz., abdominal tenderness, tympanites, sickness, pinched features, &c., but no rise of temperature or quickening of the pulse. Opium increased to one grain and a half every four hours.

21st.—Patient passed a fair night; sickness absent this morning, but abdominal tenderness, tympanites, dorsal decubitus, and pinched expression remain. Pulse 84; temperature 98°4'; tongue furred; takes small quantities of milk and brandy freely; very slight action of bowels this morning. Opium reduced to one grain every four hours.

22nd.—Patient very restless during the night; symptoms of peritonitis increased this morning; complains of nausea and abdominal pain; tympanites increased. Pulse 84; temperature 98°5'. Opium again increased to one grain and a half every four hours.—3.30 P.M.: Severe exacerbation of peritoneal symptoms; tympanites increased; whole abdomen exquisitely tender; thoracic breathing; frequent vomiting and hiccough. At this time pulse 84, weaker; temperature 98°4'.

23rd.—Patient slept the greater part of the night under the influence of opium; looks better to-day; sickness absent; tympanites and abdominal tenderness greatly diminished; breathing less confined to thorax; tongue furred; pulse 84, stronger; temperature 98°4'. Opium again reduced to one grain every four hours.

24th.—Patient continues to improve; tympanites and abdominal tenderness entirely absent. Pulse 85; temperature 98°4'; opium discontinued; tongue furred; appetite bad. A pint and a half of tepid water was injected per rectum this evening, after which the bowels acted freely.

From this time the patient continued to improve, and on Oct. 1st was quite recovered from the operation and its effects. I may state that our patient was not left alone day or night until completely recovered.

Remarks.—Of the many interesting points in this case, the most important is the remarkable fact that following a wound of the peritoneum we had present every sign and symptom of inflammation of that membrane except increase of temperature and quickening of the heart's action, the two most common—in fact, the two ever-present—attendants on inflammation. And, again, that during strangulation of the herniated portion of intestine—when we had sickness, pain around the tumour, hiccough, vomiting (which was before the operation of that character known as stercoraceous), and the pinched expression of features which is indicative of suffering and collapse—we had the heart insensible to this disordered state of the system, contracting with the utmost regularity, and the temperature of the body maintained at the normal. Nor had we at this time any deficiency in the cutaneous circulation, or in that of the extremities. Is this strange indifference of the heart to serious changes in the surrounding organs, and this unvaried production of heat in the body, to be attributed to disease of the nervous system—to disease confined to some of those nervous centres acting over limited areas which have of late years been mapped out and given “a local habitation and a name”?

I may state that no pulmonary or cardiac disease can be detected, nor have we strabismus, inequality of pupils, loss of motion, or any abnormal increase or decrease of any of the senses, or other physical sign of organic disease of the nervous system.

The case is also of value as a good example of the excellent results often found to follow dry dressing and rare interference with wounds. In this case the primary pad of dry lint was not removed until the fourth day, when it was discovered that the wound had healed by the first intention.

East Riding Asylum, Yorks.

NOTES ON A CASE OF RUPTURE OF THE EYEBALL IN A PATIENT SUFFERING FROM HÆMORRHAGIC DIATHESIS.

By A. EMRYS-JONES, M.D.,

ASSISTANT-SURGEON, ROYAL EYE HOSPITAL, MANCHESTER.

W. R.—, aged fourteen, of Waterfoot, was admitted into the Eye Hospital on Nov. 1st, 1878, under Dr. Little. The boy was a weaver by trade, and on admission, although he looked pale, he was otherwise healthy. On examining his right eye I found that the shuttle from the loom where he was working had struck his eyeball and ruptured it through the entire breadth of the cornea and sclera, and the hæmorrhage was profuse. Pads and a firm flannel compress bandage were at once applied, but in spite of repeated changing the blood kept oozing through them. Astringent applications and compress bandages were next tried, but without improvement.

Next day the mutilated globe was enucleated, and the contents of the orbit to a great extent removed, and then the cavity was carefully packed with cotton-wool dipped in tincture of perchloride of iron, kept in position by a firm compress bandage. It was next packed with cotton-wool, mixed with powdered sulphate of copper and sulphate of iron, but these were of no avail. Cotton-wool steeped in collodion, well packed and allowed to dry, controlled the hæmorrhage for a time. The subcutaneous injection of ergotine, the internal administration of ergot, sulphuric acid, and other astringents was tried. Even the actual cautery, which was thoroughly applied, proved inefficacious. The oozing was persistent for a fortnight, when the boy's father insisted on taking him home, and now, for the first time, admitted that the boy was subject to attacks of bleeding from slight causes. They were both very reticent about giving any information on this point. The pulse kept up fairly the whole time, but he became very weak and blanched. On leaving the hospital his orbit was carefully packed with cotton-wool steeped in collodion. A week later his father wrote to me that the bleeding had continued for a few days, and that ultimately the boy “fell into a faint,” and the hæmorrhage entirely ceased. In January, 1879, I saw the boy again quite in his usual health. The interest of the case seems to me threefold—1st. The extreme rarity of such a coincidence; I do not know of any recorded. 2nd. The failure of all the usually reputed remedies. 3rd. The favourable result through natural processes.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium

ST. THOMAS'S HOSPITAL.

TRACHEOTOMY IN A CHILD UNDER SIX MONTHS OLD; RECOVERY.

(Under the care of Mr. CROFT.)

THE following case, for the notes of which we are indebted to Mr. H. Percy Potter, surgical registrar, is interesting, chiefly on account of the urgency of the symptoms and the relief and subsequent recovery after tracheotomy in so young a child.

The mother stated that during the night previous to admission she noticed swelling on each side of the neck, causing the child to breathe hurriedly and with much difficulty. There was no cough. The patient had suffered from erysipelas of the arm and back following vaccination in August.

The child was first seen in the out-patient department on Sept. 25th, with erysipelatosus inflammation and œdema of

the whole cervical region, extending to the upper part of the chest; considerable dyspnoea and no croupous cough. The case was at once admitted into the hospital and placed under the supervision of Mr. Croft. An attempt was made to examine the fauces for false membrane, but it was impossible to inspect the throat owing to the swelling. A hot bath was given, and ipecacuanha wine, which induced vomiting. Relief was afforded by this treatment, but at midnight, on account of the increased dyspnoea with lividity, Mr. Potter performed tracheotomy under chloroform. The trachea was easily reached, opened by the usual vertical incision, and a silver tube was introduced. Artificial respiration was employed for several minutes. The child was placed in a tent, and steam was diffused in the atmosphere. The mother had suckled her infant throughout.

After the operation the child coughed up several small pieces of cartilage—probably from the rings of the trachea; the swelling and inflammation of the neck subsided, and an india-rubber tube was inserted, and the child did well.

WESTMINSTER HOSPITAL.

GALACTOCELE; INCISION; CURE.

(Under the care of Mr. PEARCE GOULD.)

MRS. T—, aged eighteen, first came under Mr. Gould's care in the out-patient room on Aug. 19th, 1878. She was a robust, healthy-looking young woman, who stated that two years before she struck her right breast against a chair, and three months afterwards noticed a small lump in the breast close to the nipple. She had been married fifteen months, and was confined of her first child in February. "Just a little milk came" in the right breast, but not enough to enable her to suckle with it. There was no pain in it, but as it felt different from the other, and did not secrete milk, she sought advice.

The left breast was well developed, with a good nipple, and secreted freely. The right gland was almost the same size as the left, but was almost completely occupied by a tense, rounded, fluctuating swelling, a little involuted mammary tissue being felt at the lower part; the nipple was flattened out by the swelling; the skin was not reddened, and there was no enlargement of the axillary glands. She was seen again on Aug. 23rd, when the swelling was distinctly larger and "pointing," the contained milk being visible as a white spot in the centre of a red area. A small incision, radiating from the nipple, evacuated about half a pint of creamy fluid, and the sac completely collapsed; a horsehair drain was inserted, and the breast supported by a bandage of cotton-wool. A thick, milky discharge continued to flow from the wound for several weeks, and then gradually became thinner and less, and finally ceased in March, 1879. Extract of belladonna was applied over the breast at first, and later on pressure was employed. The fluid was examined microscopically, and found to be a clear liquid containing colostrum corpuscles, oil globules, and fine granules.

Remarks.—Lactæal cysts are not common. The history and appearance of this case left no room for doubt as to its nature. These cysts have been stated to arise from dilatation of the sinuses or large ducts, or from rupture of a duct and extravasation of milk, in which case they have been found to increase "rapidly and distinctly every time the infant sucks." Here this feature was not noticed, and the history of a previous injury and inability to suckle with the breast render it probable that there was obstruction to one, or perhaps more, of the lactæal ducts. Out of seventeen cases of galactocèle recorded by Gross there had been a previous blow in two. It has been stated that such cysts never burst; this one "pointed" most distinctly, and at least threatened to burst.

FULHAM SMALL-POX HOSPITAL.

TWO FATAL CASES OF HÆMORRHAGIC VARIOLA;
NECROPSIES.

(Under the care of Mr. R. D. R. SWEETING.)

CASE 1.—Elijah B—, aged twenty-one, a compositor, was admitted on September 18th, at 3.30 P.M. He was then in a weak and exhausted state. He was rational, and stated that he had been attacked with headache and vomiting on Sept. 9th, which ceased on the appearance of the eruption on

Sept. 11th. His case was at first pronounced to be "blood-poisoning;" hence the delay in admission.

On examination the surface of the body was found to be covered with a deep-seated confluent eruption, pale and vesicular over the face, but consisting of dark hæmorrhagic pocks over the shoulders, trunk, and extremities. In the latter parts the eruption ran in patches, more or less symmetrical. The tongue was dry and brownish-black; the lips and fauces were black. The conjunctivæ of both eyes were extremely injected. The hands and lips were tremulous; the pulse was soft, highly compressible, 120. Temperature on admission, 103°. During the evening the patient vomited blood several times, which was almost black in colour. Urine also deeply tinged with blood.

On the following morning he was still conscious; answered questions rationally; had slept fairly well. Temperature 101°. There was harsh breathing, especially at the back; deep percussion was impossible. In the evening he was observed to be much more prostrate; pulse 120, feeble and flickering, temperature 103°, respiration hurried, 46. He gradually sank, in spite of stimulating treatment, and died Sept. 20th, at 4.30 A.M.

Necropsy, thirty-two hours after death.—Body badly nourished, covered with petechiæ and pocks, most abundant on inner and back aspect of arms. The left lung was emphysematous at the edges, the right was emphysematous anteriorly, and presented areas of basic consolidation. The right side of the heart was empty and flaccid, the left side semi-contracted; the valves were normal. The liver was large (weight sixty-eight ounces), and presented greenish-blue discolorations at edges. Spleen normal in size, but engorged. Stomach intensely congested, and presenting numerous small hæmorrhages in the mucous membrane, and large rugæ extending through its length. Kidneys: Pelves of both organs the sites of extensive hæmorrhages, being blocked up with dark clots. Ureters: Mucous membrane dark purple in colour, most marked at the upper and lower thirds, the middle portion being fairly normal. Bladder: Mucous membrane slightly congested, presenting a purple arborescent appearance in several parts.

CASE 2.—Grace D—, aged twenty-six, a domestic servant, was admitted Sept. 27th, at 5 P.M. She stated that she had been seized with shivering and headache on Sept. 20th, and felt languid and "out of sorts." On Sept. 24th the eruption appeared, being noticed first on the hands, and on the morning of admission she suffered from vomiting and diarrhœa.

On examination she was found to be the subject of an extensive and varying eruption. Numerous red raised and rough papules were noticed on the arms, wrists, and soles of feet, but none on face or forehead. The regions of these papules were red, indurated, and hot. Besides these there were several reddish-blue spots on forehead, and similar large symmetrical patches covering both sides of lower half of abdomen, and extending down to groins and upper third of thighs. There were also a few dark-purple spots on anterior aspect of legs. This rash was at first thought to be purpura, but from the analogy of the further development of the eruption in other parts, and the fact that it was exceedingly sparse on the legs, the usual site of purpura, the idea was dismissed.

During the evening the patient retched a great deal and vomited once, the egesta being dark and viscid. Temperature 104°; pulse 120. Port wine (four ounces) and iced soda-water and milk ordered.

On the following day the tongue was moist and dark, and there were small blebs of serum on the lips. Pulse quick, soft, and compressible, 120; temperature 102.6°. There had been some slight vaginal hæmorrhage, which patient ascribed to the premature appearance of the menses. There was still occasional retching. Evening temperature 104°. Five-grain doses of sulphate of quinine were ordered.

On the 29th the temperature in the morning was 101°; pulse 110. The vaginal hæmorrhage continued, and was more copious. Some hæmaturia was also noticed. The urine was albuminous (one-sixth). Fifteen grains of gallic acid were given every four hours.

The papules on the arms and wrists were becoming hæmorrhagic pocks. A few pocks filled with dark blood were also visible on the forehead and shoulders. The symmetrical patches on the abdomen and thighs remained the same. Evening temperature 100°; pulse 100. Patient felt sick, but had not vomited. As the hæmorrhage continued, the vagina and uterus were well syringed, first, with luke-

warm water, and then with a warm solution of perchloride of iron. The woman became restless and sleepless at midnight. A scruple of chloral hydrate was given. She slept four hours after the draught of chloral, but next morning seemed greatly prostrated and inclined to coma, and swallowing was difficult. The vaginal hæmorrhage had ceased, but there was still slight hæmaturia. The eruption on the forehead now consisted of a large blended extravasation rather than a collection of pocks, and the papules at first observed on the arms and wrists had all become vesicles, containing blood of a colour almost black. The patches on the abdomen and thighs remained as such, being, however, darker, as also were the few spots on the legs. Temperature 99°; pulse 100, very soft. A pint of champagne was given with the hope of rousing the patient, but she rapidly succumbed, and died at 6.30 P.M.

Necropsy forty-six hours after death.—Body well nourished; surface discoloured, and presenting numerous hæmorrhagic pocks and petechiæ, the latter abundant over abdomen. The edges and upper lobes of both lungs were emphysematous, the lower lobes engorged with blood; no consolidation. The pericardial sac contained half an ounce of bloody serum. The heart-substance was pale in colour; valves healthy; the right cavities were flaccid and empty; the left side was semi-contracted, and contained soft diffuent clot. The spleen was soft and congested; liver normal; stomach greatly dilated; mucous membrane congested; lower part and pyloric region intersected with thick and wavy rugæ. The pelves of both kidneys occupied by large extravasations, consisting of firm dark clots; exterior and cortex of each greatly congested; capsules readily separable, and presenting hæmorrhages in their substance. The commencement of each ureter was blocked up for an inch with a large firm thrombus, greatly increasing the lumen of the tube; the upper half of the mucous membrane of ureter was congested. In addition, there was observed laceration and partial rupture of kidney-substance at the lower part of the hilum below the ureter, with accompanying extravasation into the tissues around the organ. The bladder presented points of congested mucous membrane most marked at the neck. Mucous membrane of the vagina was of a dark purple colour. The cavity of the uterus was occupied by a reddish-brown clot; mucous membrane of fundus presented several points of hæmorrhage. The left ovary was deeply congested; right also congested and filled with corpora lutea; ovarian veins were distended and prominent. The broad ligament and mucous membrane of Fallopian tubes were of a port-wine colour.

Remarks.—Neither of the above patients possessed thoroughly protective vaccination marks, those of Case 1 being "third class," and those of Case 2 "second class." In order to explain this terminology, which is in use under the Metropolitan Asylums Board, "third class" will be held to comprise those cases in which there are one or several cicatrices, making up less than a third of a square inch of badly-foveated surface, or of surface without foveation; and "second class" will include cases in which is found less than a third of a square inch of well-foveated surface, or one-third of a square inch of badly-foveated surface. Thus, the cicatrices in Case 2 were noted as being large, but *puckered* and not truly foveated.

GENERAL INFIRMARY, LEEDS.

CASE OF APHASIA FOLLOWING INJURY TO THE HEAD.

(Under the care of Mr. WHEELHOUSE.)

For the following notes we are indebted to Mr. W. H. Brown, house-surgeon.

W. D—, aged twenty-five, a groom, was admitted on October 29th, 1879. The history of the case being that whilst he was engaged in removing a stone from a horse's foot the horse struck out and kicked him on the left side of the head. On admission he was absolutely unconscious, the pulse was slow (56), and the pupils were contracted, and respiration about 24. There was a soft elastic swelling over the left parietal bone just in front of the ear, and through this swelling the bone appeared to be depressed. There was also considerable effusion beneath the frontal portion of the occipito-frontalis muscle. About one hour after admission he became very restless, but remained quiet on being ordered to do so. He then appeared to have regained possession of all his faculties save that of speech, for

he was able to move his arms and legs according to directions and to count figures which were held up to him by holding up a corresponding number on his own hand. About twelve hours after his admission he, for the first time, made an effort to speak, but only succeeded in uttering some incoherent sounds. All symptoms of compression now passed off. In this condition he continued for twenty-four hours, sleeping somewhat heavily at intervals, when suddenly, in answer to a question put to him, he answered "Yes," and to a query put to him as to pain, "No." From this time (thirty-six hours after the accident) he gradually improved, and was able to name objects (such as a watch, keys, &c.), which were shown to him, at first indistinctly, but becoming more correct after one or two attempts. Three weeks after the accident he could converse freely and had fully regained his power of speech. He stated that when he attempted to speak rapidly he at times got confused, but this confusion passed off if he paused for a minute or two.

Rest in bed, low diet, and free purgation was the only treatment.

Remarks.—There appear to be several points of interest in this case. First, its rarity. A similar case is mentioned in Bryant's Surgery, vol. i., page 211. In this case the aphasia lasted once two months, so that the injury was probably much more severe than in the present instance. Secondly, it shows that it is possible to have complete aphasia without any other paralysis. Thirdly, the rapid manner in which the symptoms passed off, leaving the patient practically well. Fourthly, as to prognosis. The case on admission appeared to be most grave, but the manner in which it terminated bears out the late Mr. Callender's opinion that injuries to the right side of the head are more rapidly and more surely fatal than are equal injuries on the left. The aphasia was in all probability due to a concussion of the third left frontal convolution, and may have consisted of minute hæmorrhages which rapidly became absorbed.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Artificial Respiration in New-born Children.

THE ordinary meeting of this Society was held on the 23rd inst., J. E. Erichsen, Esq., F.R.S., President, in the chair. The evening was occupied by the reading of a paper contributed by Dr. Champneys, detailing the results of comparative experiments upon methods of inducing artificial respiration in new-born children, and by the discussion arising out of the paper. Drs. Matthews Duncan, Roper, Powell, and Silvester took part in the debate.

The following is an abstract of the paper, entitled "On Artificial Respiration in New-born Children; the amount of ventilation secured by different methods: an experimental inquiry;" by FRANCIS HENRY CHAMPNEYS, M.B. Oxon., M.R.C.P. The number of bodies experimented on was twenty-six, of which twenty were utilised for this part of the subject; only such as had never breathed being used. Tracheotomy having been performed, a cannula was tied into the trachea, the cannula being connected by an india-rubber tube, with a V tube filled with water, which thus registered inspiration and expiration by the rise and fall of the water, the results in the same body only being compared, and the highest effect being the standard of comparison. The methods used were nine—viz., that of Marshall Hall, Howard, Silvester, Pacini, Bain, Schücking, Schüller, Schroeder, Schultze. The conclusions were the following:—(1) Since the position of equilibrium of a stillborn child's chest is one of absolute expiration, airlessness, or collapse, no method which depends on elastic recoil of the chest-walls will introduce air into its lungs. The methods of Marshall Hall and Howard are useless as means of directly ventilating the lungs of stillborn children. (2) Silvester's method, and its modifications by Pacini and Bain, introduce more air into the lungs than any other method.

(3) In using Silvester's method the arms should be held above the elbows and everted. (4) In using Pacini's or Bain's method the legs should be fixed, the second half of Pacini's method and Bain's second method should not be employed, as the weight of a new-born child's body is insufficient counterpoise to the necessary traction. (5) In using these two latter methods the operator may face the subject, and lift the shoulders from below; by this means he is able to watch the child's countenance; and is able to introduce an equal quantity of air. (6) Schücker's method is no improvement on Silvester's. (7) Schüller's method is useless, and not free from risk. (8) Schroeder's method is useless. (9) Schultze's plan, although its power of ventilation is less than that of Silvester and its modifications, yet acts efficiently. (10) In Schultze's method the diaphragm does descend, though but slightly; its principal action, however, is on the thoracic walls, as in the Silvester group. (11) In Schultze's method it is important that the whole weight should rest (at the end of the inspiratory movement) on the index-fingers in the axillæ, and should not be distributed to the other fingers. (12) The violence of the action of the method of Schultze is not in its favour. (13) Opisthotonos always produced expiration by tension of the anterior body walls, and should be avoided. Behm's experiments, six in number, dealt with children truly stillborn in two cases only (one other having failed). His general conclusions speak highly of Marshall Hall's and Howard's methods, which, however, in the above two cases, were nearly or quite failures. His error is in not appreciating the collapsed state of the thorax in truly stillborn children.—The PRESIDENT invited discussion from those who had had practical experience of these methods. He asked how long after birth was a stillborn child recoverable; and also whether evils do not often attend the more violent measures, such as succussion or slapping, so often adopted.—Dr. MATTHEWS DUNCANS said the paper was one of great value, which would lead to results of cardinal importance in the treatment of the stillborn. Schultze's method appeared too violent, and he felt that it was desirable to induce respiration by as gentle means as possible. The author's remarks upon Howard's and M. Hall's methods showed these methods to be without practical importance or utility. His own experience was that the older methods, which he was taught were of great value, were conducted with objectionable haste and hurry, as well as violence. He remembered a case where the spleen and liver were ruptured by the over-active treatment employed in resuscitation. The method of direct inflation was unsatisfactory, the air being as often passed into the œsophagus and stomach as into the lungs. He was of opinion that Silvester's method was the best. He pointed out that recovery was possible even if the heart had ceased beating for more than a minute. In such cases the heart was often temporarily arrested; so also in stillbirths.—Dr. ROPER urged that the child frequently commenced to breathe spontaneously, even when artificial methods were being employed; e.g., he had seen a child inspire whilst the movement of expiration was being made by Silvester's method. The cessation of the cardiac beat was difficult to make out in breech cases, and he related three cases in which the child was left for dead. One of these occurred in the practice of the late Mr. Brown, of St. Mary Axe; the child was born still in the absence of the medical man; it was taken to the surgery and thence to the late Mr. Solly, who, next day, in dissecting the body, found that the heart was still beating. A second instance was of a fetus of five months and a half, which was set aside for dead, Dr. Roper attending to the mother, who was suffering from hæmorrhage. He was astonished next day to find that this immature child, which had lain on the floor for eleven hours through a cold night, was breathing, and its heart beating. Again, he once delivered a monster by the forceps; it seemed dead, and was not further attended to, but as he was leaving the room two hours later the child, which had been left aside, began to cry. Such examples showed that the new-born have greater tenacity of life than is supposed.—The PRESIDENT asked whether in the case examined by Mr. Solly the auricles or ventricles were beating.—Dr. ROPER did not know.—The PRESIDENT remarked that in some experiments he had made long ago upon animals he had found the auricles to continue beating long after the ventricular systole had ceased.—Dr. DOUGLAS POWELL asked Mr. Champneys how it happened that in his

manometer experiments the mercury often fell to zero or even below it in expiration, seeing that in new-born children the lungs are absolutely collapsed, and once inspiration has taken place they can never be completely emptied again of air. There was no doubt as to the superiority of Silvester's method on theoretical grounds. That the diaphragm was not moved was not of importance; for the condition of the infant, so far as the diaphragm was concerned and the action of Silvester's method, might be compared to the condition of extreme emphysema with a flattened diaphragm, where inspiration is wholly effected by the raising of the thorax. The diaphragm in the infant could not be much drawn up, being fixed somewhat by the remains of the umbilical cord and its peritoneal reflexions. Schultze's method seemed to consist chiefly in force applied to the axillary regions; and he related a case where Silvester's method was being tried to restore breathing in sudden death from inhalation of methylene, and where additional force employed by Mr. Nunn (whose patient it was) in the axilla aided considerably in the entrance of air, as evidenced by the greater force of the inspiratory whiff. He could not see how any elastic recoil of the ribs can be established in young infants. As soon as the lungs become the least aerated, it is impossible for them again to become completely collapsed. There could hardly be any elastic recoil until the ribs had grown, for there must be very slight resiliency in the young infant.—Dr. SILVESTER was much indebted to the author for this contribution to the literature of resuscitation. He concurred in Dr. Powell's remark as to the amount of air expired being less than that taken in at the first inspiration. He had drawn up his rules for the sake of the public, giving directions which could be applicable in all circumstances, and to meet the needs of all classes of people. Had he not done so the efforts at resuscitation might, in the hands of the rough and unskilled, have led to injury to the chest, axillary vessels, nerves, &c. Hence his directions that the operator should stand behind the subject, and should raise the arms from the elbows. He preferred himself to take hold of the hands and press the arms on the chest. Before introducing his plan he had tried thirty or forty different ways. He did not think the method used above so applicable to the still-born as to adults, as the lungs in them do not follow the raising of the ribs. He preferred in their case to directly inflate the lungs by blowing into the mouth, whilst pressing the larynx backwards against the pharynx, and to combine with this procedure that of drawing up the ribs. The readiness with which the infantile muscles and ribs can be injured must be borne in mind. The heart may continue beating as long as artificial respiration is continued, ceasing when this is stopped, and so on for many times, and yet the child not live. So that in many cases of stillbirth he believed that injury to the brain might be present, thus preventing the continuance of respiration after it had been artificially induced.—Dr. CHAMPNEYS said, of course, these experiments were far from settling the question as to which was the best method. Although quite admitting the possibility of spontaneous recovery after stillbirth, yet such instances as Dr. Roper had named were exceptional, and he did not think those who recovered after artificial respiration were to be classed with them. The reason why it was stated in some of his experiments that the mercury fell below zero in the manometer was that after the first inspiration and expiration he had altered the reading of the manometer and started afresh, so that if some of the residual air was expired subsequently the reading would be necessarily below this second starting-point. Schultze's method caused a marked descent of the diaphragm; but there was no evident rise of it in Silvester's method. The elastic recoil of the ribs is remarkable. In a very few hours after birth a new state of equilibrium is established, and the rib-cartilages have grown to the state of inspiration from that of collapse. He thought it would be of advantage if Dr. Silvester would publish a second set of rules for skilled persons, so that the best system might be carried out by medical men and others. He had made experiments which showed that it was not possible to blow air through the mouth into the trachea without some also passing into the œsophagus; and when the larynx is pressed against the pharynx to prevent the latter occurrence neither trachea nor gullet received air. But the subject of mouth to mouth inflation did not enter into the present paper, which had dealt with only one portion of the subject of artificial respiration.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Hydrocele.—Apoplexy from Embolism.—Acute Hip Disease following Osteitis of Femur.—Accident to a Lithotrite.

AT the meeting on the 22nd inst., Mr. F. J. Gant, President, in the chair—

Mr. FRANCIS MASON exhibited a man, aged forty-nine, now under his care at St. Thomas's Hospital, who had been sent to him by Dr. Price of Margate, with an unusually large hydrocele of the tunica vaginalis. The patient first noticed the swelling fifteen years ago. The hydrocele had been tapped twice—viz., eleven years and again seven years ago. The swelling now measured in the transverse circumference thirty-one inches, and in the antero-posterior direction twenty-six inches.

Dr. DOUGLAS POWELL exhibited the Brain removed from a girl, aged nineteen, who had been under his care at the Brompton Hospital suffering from symptoms of blood contamination from endocarditis, and who died on Sept. 27th, within two hours of an attack of epilepsy. She had suffered from joint pains, but never from an ordinary attack of rheumatic fever; and eighteen months before admission had an attack of inflammation of the right lung. Her health and strength had gradually failed during the past three months, since an attack of severe pain in the left mammary region, which confined her to bed for a few days. On admission on Aug. 2nd she was very anæmic and breathless; there were pain, swelling, and redness of the right ankle; the temperature was 102° 8', and pulse 130. The heart's apex was in the nipple line; action quick, but regular, with increased force. The first sound was prolonged by a high-pitched murmur from the apex round towards the scapula. The disease ran the course of subacute intermitting rheumatism, with a constantly high pulse range (100–120–130), and very trivial joint-trouble. There was no albumen or blood in the urine, but on September 6th the spleen was found to be enlarged, presumably from embolism. The evening temperature was rarely below 100°, at intervals mounting to 101° and 102°, and rarely 103°; the morning temperature being mostly about 99°. For four days previous to the fatal attack on October 27th the temperature had daily ranged between 99° and 103°. She had occasional headache, particularly for a few hours before her apoplectic seizure, but no paralytic symptoms had before this presented themselves. The post-mortem examination revealed vegetation on the mitral valve and recent granulations in the auricle; an appearance as if some vegetation had been detached from the valves, and softening of the chordæ tendineæ. There was embolism of the posterior cerebral artery and red softening of the lobe it supplied, whilst behind the plug the vessel was dilated and ruptured, blood-clot covering the base of the brain and filling the ventricles. The spleen was enlarged, and the seat of two yellowish infarcts; and an old infarct also occurred in the kidney. Dr. Powell remarked that the case illustrated the commonest cause of cerebral hæmorrhage in young people. The possibility of cerebral and other embolism hardly yet entered sufficiently into calculation in estimating the prognosis of valvular heart affections. It was most apt to occur in mitral stenosis. In mitral and aortic regurgitation of rheumatic origin it occurred, he believed, with equal frequency, allowance being made for the relative prevalence of the two diseases. Multiple embolism was, however, a necessary feature of ulcerative endocarditis, of which the present case was an example. Blood contamination shared with the more palpable results of embolism in producing the characteristic febrile symptoms of this disease, and an enlarged spleen was one of the chief confirmatory signs of the affection. He referred to the observations of Mr. Bryant and Dr. Goodhart, in the 28th volume of the Pathological Transactions, as to the effect of embolism in causing aneurismal dilatation of arteries. The difficulty in his case was the rapidity with which the dilatation and softening of vessels must have occurred. The brain symptoms might have been latent, but, on the other hand, it was not known with what rapidity brain matter could soften down.

Mr. BRYANT read a case of Acute Necrosis of the Head, Neck, and upper two-thirds of the Femur, associated with, as a consequence, acute destruction of the hip-joint. It

occurred in a female child aged six, who had been admitted into Guy's Hospital under his care with an acute abscess of the part. The abscess had rapidly formed after a fall upon the limb, three months before admission. The child, when admitted, was in a state of high fever and great emaciation. The thigh was much swollen, and the seat of obscure fluctuation. The case was diagnosed as one of acute periostitis or osteitis. A free incision was at once made in the outer part of the limb to relieve tension, and a quantity of dark-coloured blood mixed with pus evacuated. The bone was then found to be fully exposed, and the joint entirely disorganised. The head of the bone was in the acetabulum. Great relief followed the operation. The temperature at once fell, and the child gradually revived. Some months after the limb was again examined and explored. The shaft of the femur, which was found to be dead, was divided below the minor trochanter, and the necrosed head and neck of the bone removed, together with the necrosed epiphysis, which was lying bare in the acetabulum. The lower part of the dead shaft, which formed a sequestrum two and a half inches long, was likewise drawn out of an ensheathing periosteal formation of new bone. The case has gone on well since the operation.—The PRESIDENT agreed that the case was one of primary acute osteitis. He mentioned a case resembling acute hip disease, in which eventually the epiphysis was shed, and the patient recovered with a movable ankylosis. In one case he had excised four inches and a half of the upper end of the femur, being the largest extent of bone ever removed as a consequence of disease proceeding from above downwards.—Mr. OWEN thought there was no doubt the case was one of acute osteitis, and asked what was the condition of the joint at the first examination. Great benefit often followed incisions down to the bone. As to incision or amputation of the hip, he thought that in sickly children life was not long enough for nature to do the work of repair.—Dr. D. POWELL asked as to the frequency of amyloid disease in these cases, which he supposed would influence the question of amputation as against excision.—Mr. WM. ADAMS thought excision of the joint afforded the only chance in these cases, of which pyæmia was a common termination. In the case related the disease clearly extended from the shaft to the joint.—Mr. ROYES BELL mentioned a case of necrosis of tibia followed by abscess in the knee-joint, and implication of the ankle. The knee-joint was opened, and complete recovery followed on it; but in the ankle the result was not so fortunate. Had Mr. Bryant performed his operation antiseptically? If the antiseptic treatment be employed, recovery might occur without the drain of pus, and consequent amyloid degeneration.—Mr. PEARCE GOULD pointed out that in the hip-joint a considerable quantity of the diaphysis enters into the joint, unlike the knee, which is only formed by the epiphysis; so that if osteitis occur in the upper end of the femur the joint becomes affected. What was the effect on the bone of separation of the periosteum? He cited a case in which a large proportion of the femur was bared and only a small scale of bone came away.—Mr. BRYANT, in reply, said that after free incision he had passed his finger into the joint, which, together with the adjacent soft parts, had become disorganised. It was not known how long suppuration might last without giving rise to amyloid degeneration, which should not be regarded as contra-indicating surgical interference, as it was known that the amyloid change will disappear, when the cause is removed. He used antiseptic precautions, although he did not employ the spray and gauze, and even though these be used yet in some cases suppuration must occur.

Mr. COULSON read notes of a case of Lithotripsy (Bigelow's operation), in which an accident of an unrecorded kind occurred to the lithotrite. The patient was sixty-eight years of age and had suffered from symptoms of calculus for about seven years. The operation was performed on the 11th inst. The meatus urethræ having been previously incised, a large stone about two inches in diameter was caught and crushed with Bigelow's lithotrite. The stone offered much resistance to the instrument, and the fragments separated with a loud crack. Three or four fragments had been successively crushed when it was found that the screw and two pins by which the lithotrite is fastened to the shaft had given way, so that the two portions of the instrument became separated. No means for connecting the handle with the shaft could be extemporised. By percussion, however, upon the handle the blades were freed as much as possible from the debris, and the instrument removed from the bladder, some injury

being inflicted on the neck of the bladder and urethra in its withdrawal. The operation was completed by the fenestrated lithotrite, and fragments weighing 500 grains removed by the tube and aspirator. The operation occupied two hours and ten minutes, a delay of twenty minutes being caused by the accident. No bad symptoms followed, and this was attributed to the complete removal of the fragments having been effected. Mr. Coulson remarked on the enormous power of the blades of the instrument, and the inadequate resistance to the force applied by the screw, due to the imperfect manner in which the handle is connected with the shaft.—Mr. WORDSWORTH asked if it was the custom to crush such large uric acid stones?—Mr. COULSON would employ crushing in preference to lithotomy for any stone that could be grasped by a lithotrite, provided no fragments are left behind.

OBSTETRICAL SOCIETY OF LONDON.

Pyometra.—*Hydrocephalus.*—*Anencephalous Monster.*—*Maternal Impressions.*—*Chorea in Pregnancy.*—*Absence of the Vagina.*—*Congenital Abnormality of the Uterus.*

At the meeting of this Society, on November 3rd, 1880, Dr. W. S. Playfair, President, in the chair—

Dr. GALABIN showed Microscopic Sections from a case of *Pyometra* in a woman, aged seventy, who died after an operation for hernia. The uterus was distended into a cavity three inches in diameter, full of pus, the cervical canal being free. The naked-eye appearance was that of inflammation only, but the microscopic sections revealed the presence of carcinoma. In the specimen of *pyometra* shown last year by Dr. Matthews Duncan, where the case had run an apparently malignant course, and the wall of the uterus had ulcerated through, but in which Dr. Thin had reported only infiltration by pus-cells, he had been permitted to make a microscopic examination. He believed that in that case also there was new growth, and not inflammation only.

Dr. MATTHEWS DUNCAN showed a Child, born *Hydrocephalic*, with only stumps of arms, and with deformity of both lower limbs. The right stump of arm was one inch and three-quarters, the left two inches and three-quarters long. The femora were short, flexed, rotated outwards, and adducted, so that the knees were within half an inch of the anterior superior iliac spines. The mother attributed the condition of the child to a fright in seeing a dog run over, three months before delivery, and to her seeing the dog afterwards frequently in a deformed state. Four months before delivery she had a fall on the back.

Dr. CULVER JAMES showed an *Anencephalous Monster*, in which the upper part, sides, front, and back of the cranium were wanting, as well as the arches of the vertebral column, as low down as the angles of the scapula. The mother was twenty-six years old, and had had four children. There was no history of any fright during pregnancy.

Dr. HEYWOOD SMITH showed, as an instance of *Maternal Impressions*, photographs of a young woman, aged twenty-eight, whose profile showed a remarkable concavity of the face, ending in a prominent under-jaw. The mother had been frightened by a monkey about the fourth month of gestation. He remarked that among animals it was at the moment of conception that the mother was supposed to receive an impression, while in women a maternal impression was often referred to the third or fourth month.—Dr. BRAITHWAITE said that he had seen a puppy having a bifid and flattened forefoot, the owner of which said that during the mother's pregnancy a stone had fallen upon the foot and crushed it similarly to the flattened foot described.

Dr. JOHN WILLIAMS and Dr. GALABIN brought forward their report on Dr. Godson's specimens of Ruptured Tubal Foetation. Chorionic villi were discovered. The clot lay in close contact with the muscular wall of the tube, without any layer of decidua cells. The apparent amnial cavity was only three-eighths of an inch in length, and it was thought that the embryo could not have reached more than about three weeks' development. There was no corpus luteum, but only a cyst three-eighths of an inch long, containing a shrunken clot, in the ovary.

Dr. WADE related a case of *Chorea in Pregnancy*, treated by Dilatation of the Cervix Uteri. An unmarried primipara, aged nineteen, nearly seven months pregnant, suffered from

very severe chorea, which had commenced in a very slight form three weeks before admission. A faint apex systolic bruit, probably due to rheumatic fever two years previously, existed. An attempt was made to dilate the os with the finger, but owing to the incessant and violent movements of the patient the success was very partial, and there was, if anything, an exacerbation of the symptoms. Three days after, under chloroform, the dilatation was completely effected; this was followed during the day by very marked amendment, and a sound night's sleep—the first she had had since admission, and every succeeding night was equally good. On the third day after, the movements became worse than they had been on the two preceding days, dilatation was again effected on the fourth day, under chloroform. From this time steady, rapid, and uninterrupted recovery took place. A very slight occasional twitching of the fingers of the right hand continued until delivery at term of a healthy child, when they entirely ceased.—Dr. ROUTH asked to what extent the os had been forcibly dilated. Was it in any way lacerated?

—Dr. MATTHEWS DUNCAN also complained of the want of exact information as to what was meant by full dilatation. He regarded thorough dilatation, as he understood it, as a very sure cause of miscarriage.—Dr. AVELING had seen reflex vomiting from abrasion of the cervix uteri cured by the application of a solution of nitrate of silver, and thought medication should be first tried before dilatation.—Dr. FRANCIS TAYLER related the case of a boy suffering from severe chorea, who was taken to Guy's, where he remained in the taking-in room for some time. He was not admitted, but on his return home the choreic movements were found to have ceased, and did not recur. So sudden a recovery seemed inconsistent with so coarse a lesion as embolism, and the case also showed the need of caution in drawing conclusions as to therapeutics.

Dr. C. H. CARTER related a case of "Absence of the Vagina; uterus distended by retained menstrual fluid; operation; recovery." The patient, aged sixteen, had never menstruated. Pain had begun two years previously, and recurred almost daily. The urethral orifice was found large, the vagina absent. By rectal examination the finger felt the sound in the bladder with only a thin layer of tissue intervening. About one and a half to two inches up the rectum a rounded elastic mass was felt, reaching up half way to the umbilicus, about the size of the uterus at the third or fourth month of pregnancy. On July 25th the operation was performed for making an artificial vagina. After slight longitudinal and lateral incisions, the passage was chiefly torn by finger and director. Nothing like os or cervix uteri could be detected. The uterus was first punctured with the aspirator, and the opening then enlarged with a bistoury. About ten ounces of treacly matter escaped; several ounces of treacly fluid were afterwards expelled, and the same evening the dressings were soaked with fresh blood. The next day syringing out the uterus with carbolic lotion (1 in 80) was commenced. For about ten days there was some elevation of temperature, and a rapid pulse, 112 to 130, but the disturbance then passed off. When the patient went out on Oct. 11th the new vagina had narrowed a good deal, and only admitted the finger for about three-quarters of an inch. Thick sounds were passed occasionally to keep open the passage into the uterus, and menstruation took place regularly after the operation. In October of the following year an examination was made, and it was found that the ordinary sound could not be passed into the uterus, but a small-pointed sound could be passed into it three inches and a half. The author expressed to the mother his opinion that marriage was inadmissible, since delivery could not take place *per vias naturales*.—Dr. GALABIN's experience was, that the difficulty of keeping an artificial vagina in a condition fit for married life and parturition was considerable. He had had a similar case, in which also no trace of os or cervix could be detected. An artificial vagina was successfully made, and the patient afterwards menstruated naturally; but the attempt to keep the passage of full size was defeated by the fact that the pressure of the dilator repeatedly caused an opening into the bladder, though without producing any continued incontinence of urine.—Dr. ROUTH said that in his own case the patient had not died from the operation, but from the rupture of another cyst. He believed that in most of these cases the vagina had originally existed, but became subsequently adherent. He thought so in his own case, from the ease with which he tore it open. He thought that the passage could be kept dilated by using

sponge-tents, and subsequently Sim's dilators. The dilators should not be too large, and should not be worn more than a few hours at a time; they then would not cause inflammation. He mentioned a case in which Mr. Baker Brown had made a good artificial vagina, and the girl subsequently went upon the town, and consorted with Life Guardsmen.—Dr. BRAITHWAITE said there were two classes of cases of atresia, one being incomplete, a fistulous track existing. From the presence of mucous membrane in this contraction was less likely. When the atresia was complete he thought that mucous membrane might be transplanted from the vulva or from an animal, to prevent the tendency to contraction. In a difficult case, the urethra might be dilated and the finger kept in the bladder, and the thumb in the rectum, during the operation.—Dr. GODSON said that he had that morning seen a young woman for whom he had reluctantly made an artificial vagina two months since. There was no retention of menses, but she had married in ignorance of her deformity. Though a fortnight ago there was a capacious canal, it would now barely admit a penholder. He believed that such failure was inevitable, and would not again operate unless there were retained menstrual discharge.—Dr. AVELING thought that Dr. Carter was quite right in dissuading his patient from marriage. He did not agree with Dr. Routh that the majority of cases of absence of vagina were due to inflammatory adhesion. In the three cases he had seen it was evidently congenital, as the uterus was also absent, though the ovaries were present.—Dr. CARTER, in reply, said that Dr. Emmet stated that the tendency to close depended upon the passage being made by cutting rather than by tearing. He did not think that the tendency to contract depended altogether upon the absence of mucous membrane, but rather upon the contractility of the tissues, since in his case a mucous membrane like that of the labia minora was noted in the new passage. He agreed with Dr. Galabin that it was better to defer washing out the uterine cavity a short time. He did not recommend marriage in his case, because the end of the new vagina was closely attached to the margins of the opening into the uterus. No natural dilatation of this opening could occur in labour, and Cæsarean section would probably be necessary.

Dr. BRAXTON HICKS related a case of Congenital Abnormality of Uterus simulating Retention of Menses. The patient, aged twenty-four, had never menstruated. About twelve weeks ago she had severe pain in the right hypochondrium, lasting about six weeks. About the same time she noticed an increasing swelling in the lower abdomen, and recently tension had become severe. On admission a tumour was felt reaching above the umbilicus, tense and semi-fluctuating, causing distress and oedema of the legs. She had not distinctly suffered from monthly increase of distress. The vagina was nearly of normal length, ending in a kind of transverse depression, beyond which was felt the tumour, exactly resembling the uterus distended with menses. The author had had such a case, apparently exactly similar, the very extremity of the vagina and os uteri being closed. The patient was therefore placed under chloroform and a trocar plunged in, where a depression like a dilated os beyond the closure could be felt. Nothing but a little bloody serum flowed. The sound was then passed up into the centre of what seemed to be the uterus, but still no sign of menstrual fluid. Further interference was then abandoned, the tapping having been done antiseptically. In the night she became feverish, and died about thirty hours after the tapping. Post-mortem examination showed that there were neither uterus nor ovaries, but a large cyst attached to the upper end of the vagina; walls very irregular within, smooth without. It was half filled with a cheesy white matter, and the rest with dark grumous material. The wall above was thinned and perforated in two or three places, where the contents, in a fetid condition, had escaped into the peritoneal cavity. The trocar had passed through two layers of peritoneum. Probably the operation had only hastened the rupture.—A report by Dr. GALABIN on the Microscopic Structure of the Cyst was appended. The outer wall of fibrous tissue was only about one-twelfth of an inch thick. The soft material within was made up of round cells, longer than leucocytes, having a fibrillar reticulum amongst them. It was to be regarded as a soft sarcomatous growth.—Dr. ROUTH said that the practical point which came out was, that in another case the aspirator should be used to see the nature of the fluid, if any, before a trocar was employed.

MEDICAL OFFICERS OF HEALTH SOCIETY.

AT a meeting of this Society, held at 1, Adam-street, Adelphi, on Friday, November 19th (the President, Dr. John Syer Bristowe, in the chair), a paper was read "On the Action of Disinfectants on Sewage and the Living Organisms contained therein," by JOHN TRIPE, M.D. Dr. Tripe began by explaining that in this paper he used the term disinfectant in the popular sense, and that the object of the paper was to enable health officers and others to judge of the relative powers of the popular disinfectants. The first set of experiments were made in the spring of the present year by adding 2 per cent. of the disinfectant employed to 4000 grains of offensive sewage teeming with bacteriod and infusorial life. In the second set, which were not commenced until nearly the latter end of October, the same quantity was employed, but one drachm of fresh beef, finely shred, was put into each 4000 grains of sewage, and taken out at the end of three days. In the third set, which was begun about three weeks since, unmixed sewage only was employed. The disinfectants used were those ordinarily sold, as by that means they could be more fairly compared than if the same weight or volume of the solid or other substances from which they were made had been taken. The second set of experiments were made by the addition at first of 1-400th part of the disinfectant, and when it was found that this amount did not remove the offensive smell or destroy the living organisms, additional quantities were added until the proportion of one of the disinfectants to 100 of sewage was reached, this being the strongest mixture likely to be found in drains or sewers when disinfected. As a result of the effect of heat on sewage, infusoria became more lively as the sewage warmed, but at 90° F. their movements became slower, at 95° several ceased to move, at 110° all had died. The bacteria were not affected until 115° F. was reached, when the bacilli and vibrios became sluggish. At 125° all these had ceased to move; at 130° the smaller bacteria were sluggish, and at 140° had ceased to move. On the fourth day a very few of the smaller bacteria were seen to be active, but none of the bacilli, vibrios, or spirilla. The chemical disinfectants used were carbolic acid (No. 5), Burnett's fluid chlorine water (P.B.), solution of chlorinated lime (P.B.), euclorine, sporokton, hydrochloric acid, chloralum, sanitas, Condy's fluid; sanitas and carbolic acid powder were also experimented on. The first seven were used in the first set of experiments, whilst chloralum, sanitas, and Condy's fluid were selected instead of chlorine and chlorinated lime solutions. The experiments were made at different times, but each set carried out simultaneously, and therefore comparable. Carbolic acid No. 5: When mixed in the proportion of 2 per cent. all smell was removed and all living organisms destroyed. As long as twenty-one days afterwards there was no return of smell or bacterial life. When ten parts of carbolic acid were added to a mixture of sewage and beef, the infusoria but not the bacteria were destroyed and the smell removed. With Burnett's fluid, mixed in the proportion of 2 per cent., the same result followed as in carbolic acid. In the other proportion the effect was less marked. Euclorine, when added to sewage in the proportion of 2 per cent., removed offensive smell and destroyed infusoria. In the second set of experiments with the sewage and beef solution a mixture of 10 parts to 4000 had but little effect. With sporokton, added in the proportion of 2 per cent., no living organism was detected. In the second experiment the smell was but little altered by a strength of 10 parts in 4000 of the sewage and beef mixture; but when the sporokton was increased in strength to one in 300 the infusoria died, but the bacteria were as active as ever. Solution of chlorine (P.B.) and solution of chlorinated lime (P.B.) did not appear to have much action. Chloralum, when added in the proportion of 10 to 4000, did not immediately affect the smell; but on the second day there were fewer living organisms than in any other solution, except in those of carbolic and hydrochloric acid, and Burnett's fluid. Condy's fluid, when added in the proportion of twenty parts in 4000 completely failed to remove smell or destroy infusoria. In the proportion of one in 50 the offensive smell was removed, and the movement of the bacteria termo was stopped. Sanitas: The addition of

ten to 2000 of sewage and beef produced but little alteration in the smell. With one per cent. of sanitas the smell was much abated, but the living organisms were more abundant than even in the Condyl's fluid of the same strength. Sanitas powder was more energetic in its action than sanitas fluid.

In the discussion which followed, Dr. Buchanan Baxter, Dr. Buchanan, Dr. Alfred Carpenter, and Mr. Wynter Blyth took part.

Reviews and Notices of Books.

The Practitioner's Handbook of Treatment. By J. MILNER FOTHERGILL, M.D. Second Edition. London: Macmillan and Co. 1880.

It is not so very long since Dr. Fothergill published the results of many years' thought in a book which he rightly conjectured was much needed at the present day. The attempt to write a treatise upon therapeutics, not in the stereotyped fashion of taking drug by drug and retailing its properties, with an occasional hint at the value of combinations, but in a manner which should deal, firstly, with the conditions to which treatment is to be directed, and which should endeavour to give a rational and scientific explanation of measures often empirical and traditional, was one which deserved success. The speedy appearance of the second edition of this handbook is also to be accounted for by the fact of the clearness of the writer's style, the confidence with which he states his facts, and the general need felt nowadays for some sure basis of therapeutics. It would be impossible, of course, even for the author of this book to attempt to explain the *modus operandi* of all our therapeutic measures. Our knowledge of the physiological action of drugs is yet far from complete; and it is not always possible to predicate their action in diseased conditions from their known properties on the healthy subject. It is satisfactory, however, to be enabled to follow, so far as we can, a line of treatment which is based upon rational grounds; and, in aiding the practitioner to feel this additional satisfaction, Dr. Fothergill is to be commended.

There is no need for us to take our readers through this book. On its first appearance we indicated its scope, and the manner in which the various subjects were treated. The author has submitted it to careful revision, and made some necessary additions, availing himself frequently of the written experience of others on certain special points. The chapter upon "Medical Men at the Bedside," which closes the work, contains the thoughtful remarks of Dr. Austin Flint in his "Clinical Medicine"; upon hygiene in India Sir James Fyfe contributes a few pages, and so on. But the volume contains much that is original and suggestive, and beyond a few eccentricities in styles, is readable and interesting. We could have wished, however, that such eminently rational drugs as salicylic acid and jaborandi had received a little more attention than is devoted to them in the brief note appended to the chapter on "Body-heat and Fever"; and a more detailed account of the cold-bath treatment of pyrexia—scientific hydropathy—might have been given. The author also in more than one place cannot conceal his contempt for modern medical education. In fact, there runs through the book a tendency to disparage the prevalent methods, whereby he thinks that too much attention is given to accuracy in diagnosis, and too little to therapeutics and the ordinary details of medical practice. It is an echo of Trousseau's cry—for less science and more art in medicine. We venture to think, however, that the present writer confutes his own argument, for his whole book is an endeavour to raise therapeutics to the position of a science. There are, it may frankly be conceded, many directions in which the present system of

medical education might be improved; but that the modern methods of teaching have really resulted in an increased confidence in the measures adopted for the treatment of disease there can be no question; and it is a pity that Dr. Fothergill should have lessened the value of his work by a too partial preference for the old-fashioned methods of education in vogue when he was young.

A Practical Treatise on Tumours of the Mammary Gland, embracing their Histology, Pathology, Diagnosis, and Treatment. By SAMUEL W. GROSS, A.M., M.D., Surgeon to the Philadelphia Hospital, &c. London: H. K. Lewis. 1880.

THE naked-eye characters of the common variety of scirrhus are so distinguishing that its separation from other tumours of the mamma was early and easily made, and its clinical history written before its minute anatomy was known. Many of the other mammary tumours, however, are to the naked eye so closely alike that a rough examination affords no clue to their precise variety and structure, and they have been classified by different authors in various ways, and not with that histological accuracy that is now possible. The pernicious effect of an inappropriate nomenclature has been well exemplified in the confusion that the terms "adenoid," "adenoma," "glandular," and so on, have wrought in the study of non-cancerous growths, and the presence of gland elements has been commonly held sufficient to prove the essential nature of the entire neoplasm. A more illogical conclusion can hardly be arrived at, and in other situations the error would not be made. It is certainly strange that the old terms and classification have continued to be used so long, in spite of the great progress of histological knowledge and the improved classification of tumours in general. Dr. Gross has approached the subject from the modern standpoint, investigated it afresh, and classified mammary tumours according to their minute anatomy, and in harmony with the general classification of neoplasms. We cannot here notice *seriatim* the many interesting facts brought out by Dr. Gross, but must content ourselves with indicating some of the main points in which his views differ from those commonly held in this country. He, first of all, divides solid tumours into those derived from the periglandular connective tissue, which may be either mature—fibroma, lipoma, myxoma, chondroma—or immature, embryonic—sarcoma; and those derived from the secreting elements, and composed of epithelium, which may be typical—adenoma; or atypical—carcinoma. Angeliomata and neuromata form another separate class, and primary cysts form another group by themselves. The mere presence of gland structure in a neoplasm is rightly held not to constitute a glandular tumour, as it is obvious that a growth springing from the periglandular tissue must, at any rate at some period of its life-history, surround and include many acini and ducts. But the term adenoma is applied solely to tumours composed of new developments of gland acini, and, more rarely, ducts, having a likeness more or less close to the mamma of a female advanced in gestation. Thus defined these adenomata are found to be very rare. The changes excited in the acini and ducts of the glands by periglandular growths are fully described; they are irritative hyperplasia of the lining epithelium, dilatation by centrifugal growth of the tumour into slits, fissures, or cysts, into which the true tumour tissue fungates. The intra-cystic growths of these formations, then, although found within dilated ducts or acini, are not accurately described as papillary, or other outgrowths from them, but are masses of the periacinous tissue bulging into and dilating the gland spaces. These views, we think, will meet with general adoption, as more in accord with our present knowledge than others for-

merly promulgated. Investigation of cancers has led Dr. Gross to hold that they spring from the pre-existing glandular epithelium, and that their extension is not by any spermatic influence, but by the multiplication of already cancerous cells. We are unable to follow Dr. Gross in one of the distinctions he draws between adenoma and carcinoma; he states that in adenomata the epithelial collections are contained in cavities lined by a membrana propria of endothelium, while the cell masses of a cancer are in connective tissue spaces without any such lining. Even were it certain that there is such an "endothelium" beneath the glandular epithelium, it is undoubted that cancer spreads along lymph channels, and that its masses of cells are thus liable to be surrounded by a true lymphatic endothelium. The part of the work that deals with the clinical features of the different classes of tumours is well done and very valuable, although a little too much importance is given to the percentage frequency of various occurrences. The work opportunely supplies a real want, and is the result of accurate work, and we heartily recommend it to our readers as well worthy of careful study.

NAVAL MEDICAL SERVICE.

NEARLY a year has gone by since higher rates of pay were secured to the Army Medical Service, and more than half a year ago the Admiralty Committee closed its doors, being replete with such evidence as it required; but as yet its labours have yielded no fruit, the utmost secrecy being maintained. It is safe to say that discontent pervades the Service, from the lower stratum, where men of some standing find themselves associated with those whose competitive marks are too low for publication, up to those who have reached inspectorial rank, the general question being, When is an end to be put to this state of uncertainty? Credulity is put to the test on being semi-officially told that it rests solely with the Treasury, which, it is thereby intimated, is unwilling to pay the medical officers of the navy on the same scale as that enjoyed by the army.

Deeming that as experts in professional matters we may strengthen the position of the Admiralty *in re nautica medicæ*, we offer with respect what we assume to be just and due requirements. We know well that our naval brethren regard as their right the shorter periods—in ratio of four to five—for increase of full pay, &c., given to them over the army service, by Order in Council of July 6th, 1866, to compensate their compulsory loss of time on half-pay; and we conceive that to be justly their due until half-pay is abolished. The difference thus established, existing till the issue of the last Army Warrant, was over 7 per cent. of full-pay in favour of the navy, taking the whole career of medical service in executive rank, if unpromoted, to cover thirty years. We claim the renewal of this principle of action in the forthcoming Warrant, and offer for consideration a scheme by which this may be effected.

Adhering to the same amount of increase as in the army, of 2s. 6d. a day, but shifting the period for that increase in accordance with the principle of 4 years in the navy against five in the army service, it necessarily follows that the army maximum of 27s. 6d. will be attained with fewer years of full-pay service in the navy than in the army, necessitating a further advance of pay to 30s. On the other hand, the age of the naval officer will be co-equal, and thus it will always be easier to complete 30 years' service earlier in the army than in the navy. In fact, in the latter few will exceed 25 years in executive ranks, but the inducement of higher rate of pay will stand good. The War Office is actuated by the idea of facilitating early retirement, while the Admiralty is not thus inclined, and its views may find

support in an increase of pay at ten years' service—the earliest retiring point with gratuity for the army. At 20 years there lies the point long sought for voluntary retirement by naval surgeons, whom the Admiralty do not wish to lose, but can only retain by inducements. We

Proposal for full-pay of executive ranks.

Navy, full-pay.						Averages for 10 year term, in round numbers.	
Years of service.	Term.	Per diem.	Per annum.	Totals for term.	Totals for 10 years.	Navy.	Army.
						Proposed.	Actual.
1st term	{ - to 4	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£	£
	{ 4 „ 8	4 0 11 0	200 15 0	803 0 0			
	{ 8 „ 10	4 0 12 6	228 12 6	912 10 0

	{ 20 „ 22	3 1 7 6	501 17 6	1505 12 6			
	{ 22 „ 25	5 1 10 0	547 10 0	2737 10 0			
Total full-pay, 30 years					5155 12 6	515	479
					11341 7 6	378	357

N.B.—Under the Order in Council, July 6th, 1866, the difference of full-pay of the executive ranks stood at 7½ per cent. in favour of the navy. By this proposed scale the same would be below 7 per cent. for the full period of service.

submit as such the fixture of terms for increase of full and retired pay not at, but beyond, that period, after 22 years' service; but the right to retire after 20 years must be assured.

Our advocacy herein is limited to the rank and file of the Service. The question of raising an equivalent to the rank and immunities of brigade surgeons in the army, and the social question of cabin accommodation, are matters which, though important, we do not discuss in this article.

BRITISH MEDICAL ASSOCIATION.—The meeting of the British Medical Association for the year 1881 will be held at Ryde, in the Isle of Wight, to which locality the Association has received a cordial invitation from nearly the whole of the medical profession in the island. Mr. Benjamin Barrow has been appointed president-elect. The council of the town of Ryde have passed a resolution that the whole of the corporation buildings, which are numerous and spacious, shall be placed at the disposal of the reception committee. The address in Medicine will be given by Dr. John Syer Bristowe, London, of St. Thomas's Hospital; the address in Surgery by Mr. William Dalla Husband, of Bournemouth, consulting surgeon to the York County Hospital; and an address in Obstetric Medicine by Dr. John G. Sinclair Coghill, of Ventnor. The following grants in aid of scientific investigation for the year were made, viz., Dr. McKendrick and Committee, Glasgow, for a continued investigation on anaesthetics, £25; Dr. Gerald Yeo, London, on the efficacy of the antiseptic method in injuries of the brain, £50; Dr. Thin, London, for a continued investigation on parasitic skin diseases, £25; Mr. W. North, London, for a continued investigation on the relations which exist between nitrogenous egesta and muscular work, £50; Dr. J. Hamilton, Edinburgh, an investigation on the pathology of the brain, £30; Mr. Watson Cheyne, London, an investigation on the relation of organisms to septic diseases, £25; Dr. Augustus Waller, London, an investigation on the time and relations of muscular contractions in the human body in health and disease, £20; Dr. Alexander Ogston, Aberdeen, a continued investigation on the relation between bacteria and surgical disease, £10; Dr. Newman, Glasgow, a renewed grant in aid of an investigation on the functions of the kidney, £10; Drs. Braidwood and Vacher, Birkenhead, to illustrate the third and final report on the life history of contagium, £20.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 27, 1880.

THE relation between medicine and pharmacy formed the subject of a joint discussion between chemists and doctors in some meetings which have been held in the Philadelphia College of Pharmacy, with the object of improving the relations between the two classes. The discussions, which have been summarised in an article in the *Pharmaceutical Journal*, deal with many points which are of equal interest on this side of the Atlantic. If we are to judge from the tone of the speakers, they have a better chance of settlement in America than in this country, although it is always difficult to know how far statements made on such an occasion are really representative. The subject of patent medicines was first discussed. Dr. SWAYZE deprecated their use, and urged pharmacists to abandon and discourage their sale, and a resolution was passed to ascertain how far the proposal would be agreeable to the dealers in drugs who are directly concerned. We fear, however, that the proposal is impracticable. The public requires educating as much as the chemists; as long as patent medicines are demanded patent medicines will be prepared, and pharmacists will have no choice but either to lose custom or to act as distributors. The *American Journal of Pharmacy*, however, approves the movement, and suggests the desirability of discarding all signs and circulars recommending patent medicines, and in this we thoroughly concur. Druggists, by the way in which they lend themselves to the advertisement of quack medicines, aid considerably in their diffusion. In order to save a few pence in paper, many of them will distribute advertisements of patent medicines by using them as wrappers, a practice which is strongly to be deprecated. The American journal goes farther, and urges medical men to discard the use of "specialities" which are not patent medicines, and the constituents of which are known. Here, however, we are on different ground. There is no doubt that of late years such specialities have been prescribed by physicians much more than formerly. These preparations have come to us largely from the other side of the Atlantic, and it is difficult to class them all together, and, with our contemporary, to draw no distinction between them and patent medicines. It is not surprising that they are looked upon with some disfavour by pharmacists, since the profits derived from their sale must be very much less than those obtained upon medicines dispensed from an ordinary prescription.

An occasional relation between medical men and chemists, which was passed over by the Conference as "an evil difficult to reach," should certainly be condemned in the strongest terms. We refer to the arrangement for "mutual advantage sometimes made between physicians and pharmacists," by which we understand an allusion to the system of a percentage return to the prescriber on the price of medicines dispensed. It is idle to affect to ignore that such an arrangement is occasionally made even in this country,

but to one of the parties to the compact, the physician, it is simply disgraceful. To obtain out of the pockets of his patients an addition to his fees unknown to them is a dishonest procedure. Unfortunately the practice is not confined to chemists. Not long ago we saw a circular sent out to the profession by a manufacturer of apparatus used in sickness, openly offering to return to the recommender a percentage on the price charged for apparatus supplied to his patients. It is rumoured that there are surgeons who are not ashamed to accept a similar percentage from the makers of orthopædic and other instruments. Such procedures are discreditable enough to the tradesmen concerned (if they do not indeed deserve a less honourable name). What is it, then, to those who profess to belong to a "liberal profession"? In the case of dispensing chemists, it is notorious that to facilitate such an arrangement is the real object of the private lists of formulæ, to be prescribed by the numbers they bear, which have been issued by some firms of chemists reputed to be respectable. Against everything which indicates such a system, medical men who value the reputation of their profession for honesty, much less for honour, should resolutely set their faces, by refusing to give any countenance to the tradesmen who are willing to adopt the system, and they should take care that the tradesmen implicated are aware of the fact.

Another topic which was considered at the Conference is a sore subject with our profession in all countries—that of counter-prescribing. The practice has been often condemned in these columns, and we need say little more in deprecation of a custom which, under legal toleration, has flooded the country with practitioners destitute of any medical education, unqualified, and practically irresponsible, who for the sake of a small profit, in every town in England, deprive the medical practitioners of one-half the work which should legitimately come to them, and occasionally furnish the practitioner with some of his most difficult tasks. The discussion was not conducted without bitterness, and ended in the passage of a resolution which was probably intended rather as a salve to the medical men present than as having any practical value:—"That as the diagnosis and treatment of disease belong to the province of a distinct profession, and as a pharmaceutical education does not qualify the pharmacist for these responsible offices, he should, where it is practicable, refer applicants for medical aid to a regular physician." The chemists who took part in the discussion denied that the strictures expressed applied to them, and quibbled over the difficulty of defining exactly what is to be understood by "prescribing over the counter," and of deciding how far the pharmacist is justified in expressing an opinion as to the choice of simple remedies. A definition could readily be obtained from the Council of the Pharmaceutical Society, or if any member of the Conference were to spend half an hour one Saturday evening in almost any chemist's shop, in London or out of it, he would scarcely fail to be able to frame a definition of counter-prescribing at least twenty times over. A trade journal positively has a section—the "Counter Prescriber"—to put the druggists "up to" the drugs to give for such and such symptoms. Counter-prescribing is not only a system which is injurious alike to patients and medical men, but it is one that bears

the impress of ingratitude to the medical profession. The changes in the mode of medical practice, the extensive adoption of the system of prescriptions, instead of supplying physic, have put an enormous amount of business into the hands of Pharmacy. We would suggest that medical men should resolve to discountenance all chemists who are known to cultivate counter-prescribing, and to encourage by their help those (if any such are to be found) who avoid it altogether.

Much discussion was devoted to the subject of the unauthorised repetition of prescriptions. It was maintained that a physician does not sell his prescription, but merely his advice, and that he suffers a pecuniary loss by the unauthorised and unlimited repetition of the medicine. The question is one of great difficulty. It may be held that the prescription is really part of the advice, to which the patient has a permanent claim, and however inconvenient such a claim may sometimes be, its practical disputation is scarcely possible. It has been proposed to mark on all prescriptions that they are not to be repeated without authority, but the public would certainly rebel, and successfully, for they would find not unwilling allies in the dispensers. This and the other subjects have been often before discussed, but not often in verbal conference. We wish that we could see in the attempt which has been made at Philadelphia more promise of ultimate benefit from such joint consideration of questions of mutual importance.

THE attack on the position held by anatomy in the education of the medical student, which was made by Professor MICHAEL FOSTER in his address to the British Medical Association at Cambridge in August last, could scarcely be expected to be passed over by anatomists without protest or reply. The conclusions which the Cambridge Professor put before his audience have called forth a spirited answer from Professor TURNER in the address at the opening of the new Anatomical Buildings of the University of Edinburgh which we have recently published. The attack and the defence are alike worthy of the writers and of the cause at issue, and will be earnestly and carefully studied by those who have the direction of medical education [in this country. The ideas thus brought into contrast will also have great interest for both students and practitioners, for the predominance of the one or the other view will determine the education of the medical man of the near future. Professor FOSTER, in urging that anatomy is mainly of benefit as a discipline, seriously undervalues its practical utility by appealing to the ease with which anatomical minutiae are forgotten as soon as the examination ordeal has been passed. Topographical details undoubtedly quickly fade from the memory, but anatomy is not alone among the sciences in this respect. Details of most sciences do not linger long, and physiology assuredly can claim no superiority here. A minute knowledge of the electrical phenomena of muscle and nerve, or of the statistics of nutrition, will scarcely be remembered any longer than the relations of an artery or the exact attachments of a muscle. From this point of view, therefore, little can be advanced on one side of the question that cannot be similarly urged on the other; for just as the larger and more important physiological conclusions are likely to be prominently retained, so the anatomical facts which have a

direct bearing on medicine and surgery are rarely forgotten, especially if the study of this science is not abandoned in the early years of the curriculum, but is carried on for some time after the student has familiarised himself with cases of disease in the hospital wards. We are disposed to think that the study of anatomy is often given up at too early a period, for it is when the practitioner is brought face to face with disease that he begins to appreciate the real practical utility of a knowledge of topographical anatomy, and it is then that he begins to regret his premature exit from the dissecting-room. The value in surgical operations of careful manipulation and ready discrimination of tissues, and the advantage of a correct knowledge of the topography of the viscera to the physician, are so very obvious, that they might have been mentioned by Professor FOSTER as a set-off when he objected to the amount of time which the student spent on topographical anatomy. Every surgeon who has secured a reputation as an operator in modern times has, as far as we can recall, been a most diligent and painstaking dissector. Moreover, if the mere manual dexterity which every good surgeon must possess be not acquired during his stay in the dissecting-room, it is but rarely obtained in later years. The question at issue, however, is much broader than that of mere practical utility, so very important as this is. Is the disciplinary power of anatomy on the mind so great as to justify the amount of time which the medical student devotes to it? Is physiology the equal of, or even superior to, anatomy in this respect? These are the questions which must be decided, and on their decision the relative place of these sciences in the medical curriculum must be determined. The advantages of the study of anatomy in disciplining the mind, as laid down by Professor TURNER, are, that it is specially adapted for cultivating habits of observation, accuracy, and patience, and for strengthening the memory and reasoning powers; and these are surely sufficient to give it a foremost place in all medical educational schemes. In this estimate of its value Professor FOSTER in the main agrees. "In past years it has served as the chief culture of the medical student—as the chief means by which the rough materials coming up to our great medical schools were trained to habits of accuracy, of exactness, of patient, careful observation, and their memories strengthened by exercise for the subsequent strain which would have to be put upon them by more strictly professional learning." The only point claimed by Professor TURNER which is not admitted by Professor FOSTER is the important one of its effect in developing the reasoning powers. This difference of opinion is dependent on the standpoint from which the science is looked on. Professor FOSTER says that anatomy is a sterile subject, whose separate details hang loosely isolated in space, held together by no theory and no ideas; whilst for Professor TURNER the science embraces not only morphology but something more—viz., ideas of structure and construction, as well as conceptions of form, position, and relations. Thus anatomy, in respect to the reasoning faculty, is mainly regarded by the one in the light which it presents itself to the professional crammer; whilst in the mind of the other it is surrounded by all the traditions engrafted on it by a succession of eminently philosophical teachers. Indeed, to the latter it is the true preliminary, not only to medicine and surgery, but

to physiology and pathology also; and we most cordially agree with this estimate of the position of anatomy, if it be considered in its wider relations, and as every real teacher should encourage his students to study it. Even if physics and chemistry exercise a discipline on the mind similar to anatomy—and this we are not inclined to admit,—it is but rare that a medical student enters on his studies with the advantages of a thorough training in these sciences, and it is only by a *thorough* training that their educational effects are secured. Moreover, such students have obtained a discipline which might relieve them, as far as mental influences are concerned, from a study of a great deal of physiological as well as of anatomical details. The power of continuous application and of the mastery of facts is already theirs. But the untrained student is still the rule, and not the exception, as Professor FOSTER'S experience seems to imply, and that he can be as easily trained to habits of accuracy, precision, and patient observation by the study of physiology as of anatomy, chemistry, or physics, is a proposition which we doubt very much, and is by no means in accord with our experience. When we are told on physiological authority that the average length of life of new physiological facts—a very curious use of the word *fact* to us—may be reckoned at about three years, we can understand its influence in training the mind to reason on data of mixed and uncertain value, and of strengthening the faculty of struggling to a conclusion out of the confusion of conflicting facts and views. In many cases unfortunately the conclusions are afterwards found to be untrue, and the reasoning faulty, owing to defective data rather than to any illogical course of reasoning, so that the student too often halts hesitatingly at a conclusion, or carries an erroneous theory with him throughout his subsequent career, and bases his medical practice thereon. Of course such disastrous results can only happen when the student does not appreciate the true methods and value of physiology and fails to disentangle theories from facts; but how large a proportion of men fail in a just discrimination of these essentials? Physiology at present is far from being an exact science, and in this lies both its strength and its weakness as a discipline for the mind. As it gains in exactitude and precision—in fact, the nearer it approaches the physical sciences—the greater will its influence be in inducing habits of accuracy and observation, but these cannot be gained without the sacrifice of its present efficiency in developing the power of inference from approximate data only. Cultivation of this faculty is of the utmost importance during the period of studentship, and too much stress cannot be laid thereon, for it is ever in demand in the daily life and work of our profession. Whilst we therefore entertain a high regard for the disciplinary power of physiology in this special respect, we cannot agree with Professor FOSTER that the present relations of the two sciences should be reversed, but must firmly urge that physiology can only at present be permitted to supplement anatomy in medical education, whether we regard its practical utility or its value as a mental discipline. Indeed, we are inclined to regret that the time at the disposal of the medical student does not permit him to spend a winter session in gaining an insight into the details of anatomy, before he is brought face to face with the less obvious and more abstruse deductions of the science of

physiology. If this could be done, not only would both sciences, but the arts of medicine and surgery also, be immeasurably improved.

THE vacancy in the Crown appointment for Ireland in the General Medical Council, by the resignation of Dr. ALFRED HUDSON, gives the Government an opportunity of reverting to the original design of these Crown nominations. A study of the nature of the case and of the state of feeling at the time of the passing of the Bill, both among statesmen and members of the profession, goes to show that the Crown nominations were intended as a means of supplying members of Council who should be familiar with general practice and with the defects of medical education and examination, as shown by the experience of general practitioners. The overwhelming representation otherwise secured to universities and corporations makes it quite unnecessary to give them further representation. On the contrary, to make the Council effective and less considerate of the mere pecuniary interest of corporations, it is in the highest degree desirable to select as Crown nominees men who will really take a public and practical view of questions affecting medical education and registration.

The Government will very soon be asked to complete the Medical Acts by amending them. But pending this action on their part, it cannot do a more liberal or a more proper thing than by using its powers as Crown vacancies occur so as to make the Council really representative of the experience and the intelligence of the great body of general practitioners. The great physician whom Dr. HUDSON succeeded—Dr. STOKES—was so unfamiliar with the case of the general practitioner that he confessed, with his unfailing truthfulness, that he had never been in the chamber of a lying-in woman. It is not to be wondered at, with so many practitioners in the Council in the fashionable ranks of practice, that great branches of practical medicine and great lines of practical medical education are overlooked. We commend to the Lord Lieutenant of Ireland, and to Mr. FORSTER, so familiar with both Ireland and the question of medical reform, the views that we have set forth. The courtiers and the corporations will give them other advice, and urge them to pile up representation on the over-represented medical authorities, many of them, like the University of Oxford, having no claim to be so considered. We venture to believe that, as the late Government gave the last Crown appointment to a general practitioner, the present will do likewise.

IN 1877 Dr. TAPPEINER published an important series of observations on the production of tubercular disease in the dog by the inhalation of the sputa of persons suffering from phthisis. He has lately extended his investigation by an attempt to ascertain whether the inhalation of material from scrofulous glands is capable of producing the same effect, and the results have been published in VIRCHOW'S *Archiv*. If scrofulous diseases are indeed identical with tubercular processes, as it is fashionable now to assert, the effect of inhalation of gland-pus ought to be the same as that of phthisical pus. The material for the experiments was pus from a scrofulous boy, five years of age, with suppurating glands. Half a gramme of pus was obtained daily, mixed

with 100 grammes of water, and the dogs were made to inhale the atomised mixture for a quarter of an hour during about ten days. For purposes of comparison, two dogs were similarly treated with phthysical sputa. These two, and one of the dogs treated with the gland-pus, were killed and examined twenty-three days later. The organs of the latter were found to be perfectly normal, although the animal had presented a cough and loss of weight. In the two dogs treated with phthysical sputa, tubercular nodules were found in both lungs and spleen; their nature, from the microscopical characters, was beyond doubt. The two other dogs treated with gland-pus were killed and examined thirty-three days after the commencement of the inhalation, and the organs were also found free from tubercle. The same negative result was obtained in the case of two dogs killed on the twenty-ninth day after the inhalation of gland-pus.

Further investigations were made as to the period of incubation from the commencement of the inhalation of phthysical sputa until the tubercles are distinct in the lungs. One dog was killed on the thirteenth day after the commencement of the inhalation; it had coughed for eight days, and had lost three-quarters of a pound in weight; no tubercle was found in the organs. In another dog, killed on the nineteenth day, also, no tubercle was found. It thus appears that the period of incubation is more than nineteen days. Another dog, treated at the same time and in the same way with phthysical sputa, was killed three months after the commencement of the inhalation, and abundant tubercles were found in the lungs and pleure.

By the suggestion of Professor WALDENBURG, two other dogs were treated with sputa from simple chronic bronchitis, fifteen grammes daily for ten days; and they were killed on the twenty-eighth day after the commencement of the inhalation. The post-mortem examination showed both lungs to be perfectly normal, without a trace of tubercle. The experiments were made at Berlin, and the pathological results ascertained by GRAWITZ, ISRAEL, and FRIEDLANDER, under the supervision of VIRCHOW, so that the facts appear to be beyond question.

The conclusions drawn by TAPPEINER from these experiments are: (1) The inhalation of phthysical sputa by dogs, even in small quantities, produces with certainty tuberculosis of the lungs, with or without general tuberculosis, especially of the spleen. (2) The stage of incubation is, in dogs, longer than nineteen days, but shorter than twenty-three days. (3) The inhalation of scrofulous caseous pus from glands produces no infection—a fact which indicates an essential difference between scrofulosis and tuberculosis. (4) The inhalation of the sputa from chronic bronchitis is equally ineffective.

The facts ascertained in these experiments are certainly of a very important nature. The period of incubation, however, can hardly be fixed from so small a number of experiments, since it may not improbably be subject to considerable variation. But these observations constitute experimental confirmation of the infection of phthisis, to which many clinical facts point, and they indicate the probable mode, by which the infection is produced. The difference in the effect of scrofulous pus and phthysical sputa, if not entirely conclusive as to the difference between tubercular and scrofulous affections, indicates that we must

still pause before we abandon the older view. That view rests, we must remember, on clinical facts, which were so well described long ago by Sir WILLIAM JENNER; and these facts must be explained away if we are to accept, as Dr. HILTON FAGGE would have the members of the Pathological Society accept, the results of inoculation experiments as conclusive evidence of the identity of the two conditions.

WE publish elsewhere a copy of the instructions issued by the Government of India, defining the relative authority of the Surgeon-General with the Government of India and the Surgeon-General, Her MAJESTY'S Forces, over the officers of the Indian Medical Service. These instructions appear to be made in accordance with the General Orders issued in January and March last. They place all medical officers in civil employ and medical store-keepers under the orders of the Surgeon-General with the Government of India, and all those employed on military duty under those of the Surgeon-General of the British Forces. All medical officers are to be available for military service when required, and none are eligible for civil service until they have completed two years' actual military duty. Rules are also laid down for the mode of proceeding in applications for medical officers for civil employment, and with regard to the keeping of records of services, confidential reports, and other documents relating to the officers. These instructions appear to be merely such orders as might naturally be required for the clearing up of difficulties connected with the working of a new system, and do not seem to make any alteration in the principles laid down in the previous General Orders. They evidently are not in any way the result of the inquiry which the Governor-General intimated his intention of making into the principle on which the recent reorganisation was based, and the changes which may be deemed necessary to remove the grievances of which the Indian medical officers now complain. The Marquis of RIPON has not yet had time to make a full investigation of the subject, but it appears to us probable that ere long he will effect considerable modifications in the service, and not improbably recommend a separation of the military from the civil branch, and an amalgamation of the Indian with the British Army Medical Service.

Annotations.

"Ne quid nimis."

THE DEATH OF SIR ALEXANDER COCKBURN.

THE lamented death of Sir Alexander Cockburn has cast a genuine feeling of bereavement over the legal profession, and awakened the regretful sympathy of the community as a whole. He was a man who not only tried to do his duty, but in an exemplary manner succeeded. He served his country well, and few patriotic public servants have done as good work with so little demonstrative claim for acknowledgment or with better tact. The death of this much respected gentleman should be a warning to the "hale and hearty" of advanced age. It is not only expedient but indispensable to husband the residue of vital force when the stock is getting low. Sir Alexander Cockburn was not the man to spare himself, and up to the day of his death he, with very few intervals, worked as hardly and intensely as he had done in the prime of his life and vigour. We do not say that this

was bad policy in itself, but it was not so wisely carried out as it might have been, considering the exceptional sagacity of the man of whom we are speaking. The judges are compelled to take muscular exercise when they can, and if they did not walk more than other men of their class, they would suffer the effects of sitting long hours in densely-crowded and ill-ventilated courts. There cannot, however, be any question that a long walk on an excessively cold day, after a sitting, was not the least exacting form of exercise which a man so advanced in years as the late Lord Chief Justice could have taken. The lesson of the event may be a timely warning to the aged and energetic who "feel well" to avoid throwing too much work on organisms, which must, in the nature of things, be weakly even when they seem strong. It is better to take the "constitutional" before the day's work than after it. The exercise a sedentary man takes immediately before his dinner should be comparatively gentle, and certainly moderate. When the mental and nervous parts of the frame are weary, or even exhausted, is not a time for work. Much harm results from the ill-founded hypothesis that we can rest one part of the body by working another. The organism is more closely knit together, and healthy work is more dependent on harmony of activity, than many seem to suppose. General sleep is made up of many minor forms of sleep, and healthful and safe exercise is scarcely possible when any part of the system is severely fatigued.

EDUCATION IN WALES.

IN an interesting pamphlet entitled "Higher Education in Wales," the Rev. D. J. Davies, Fellow of Emmanuel College, Cambridge, has set forth some remarkable facts concerning the ability of Welsh children. Taking statistics as given in the two last reports of the Committee of Council on Education, he finds that the chief sources of income of Board Schools are the rates and the Government grant which varies with the proficiency of the children. Now the average English child earned, in 1875, 15·4 per cent. of the total maintenance at school, while the average Welsh child earned 22·6 per cent. of the cost of its maintenance. In the following year the percentages were 16·0 for England and 24·4 for Wales; in 1877, 18·3 for England, and 29·0 for Wales; and 1878, 19·6 for England and 31·1 for Wales. Or, as Mr. Davies forcibly puts it, "an English ratepayer who pays £5 towards his school would have to pay only £4 17s. 6d. if all his geese were swans—if all his children were Welsh children." A scheme is now on foot to improve and increase the educational resources in the Principality, and it is to be hoped that the State will be as liberal in this point as it has been to Scotland and Ireland. Two proposals are under consideration—one the foundation and endowment of a Welsh University; the other the establishment of training schools and colleges where lads of promise could receive special training in order to compete for scholarships at the established universities in England. Certainly the latter scheme promises to be more generally useful, though, from sentiment, there are some who favour the former. A Welsh university, however, would soon sink into a mere training college for clergy, since the lads destined for the bar or the medical profession would, if they wished to escape hopeless isolation, continue to seek their education either at London, Manchester, or some other populous centre. Indeed, if a lad had to leave home at all he would probably live as cheaply in England as at Cardiff, Swansea, or Bangor; whilst the railway fare would be only a trifling consideration. So many Welshmen have earned distinction in our profession, and conferred honour on it, that we should regret the success of any scheme that would limit many of them to a sphere of merely local usefulness or celebrity. Although, according to Mr. Davies, the Welsh child beats

us in the blue book statistics, we should be sorry to miss him as a competitor in our mature years. We hope the establishment of training-schools on a liberal scale throughout the Principality will enable an ever-increasing number of Welsh lads to come forward and compete on equal terms with English, Scotch, and Irish students at our already existing universities. In such a race every British-born subject should start on equal terms; and as the Welsh only ask for what has been already conceded to the Irish and Scotch, it is but just that their request should be allowed.

THE EXTINCTION OF THE QUEEN'S UNIVERSITY IN IRELAND.

THE Queen's University has resolved not to die quietly or without a protest against its extinction. For this purpose Convocation have asked the Prime Minister to receive a deputation. The chief force of their case is in two propositions: first, that the late Lord Chancellor grievously misapprehended the nature of the university, describing it simply as an examining board, whereas it is a university of the strictest academical type that has yet been realised in the British Isles, and, by his own misapprehension, misled Parliament; secondly, that the systems of teaching and of examination, adapted to each other in accordance with an experience of thirty years, have worked well, and are increasingly appreciated every year. As regards the Faculty of medicine and the Degrees in medicine, we think there can be no doubt that the Queen's University was doing a very valuable work, the interruption of which will be a misfortune.

COLD FEET.

IT is, as we have often laboured to show, a mistake to suppose there is any warmth in clothes. Animal heat is the direct result of changes going on within the body itself. Nutrition by food, and the discharge of energy by exercise, are the efficient causes of heat. Clothes "seem" to warm because they prevent the cold air and objects with a capacity for heat which surround the body from attracting the heat generated within its organism. The clothing is simply an insulator. It follows that it should be light in weight, and above all things that it should permit the free and full circulation of blood through every part of the system—to the end of every finger and toe—and that the muscular apparatus of the extremities should be in perfect working order. If we will wear foot-coverings, whether boots or stockings, which compress the feet and render the separate action of each toe impossible, it is simply absurd to expect to be warm-footed. Heat is the complement of work and nutrition; and if a part of the organism is so bound that it cannot work and its supply of blood is limited, it must be cold. The resort to stouter and heavier clothing under such circumstances is simply ridiculous. Generally it is the stockings that compress the feet. The garter acts as a ligature, and diminishes the blood-supply, while the stocking itself acts as a bandage, and impedes the circulation through the extremity. Let anyone who doubts this try the effect of wearing what is called a "well-fitting"—that is, a tight kid-glove in cold weather. Hard unyielding foot-cases, such as stout boots with no space for the toes to play and no spring for the natural action of the arch of the foot, increase the evil. The first conditions of warmth are, therefore, free action and a full blood-supply. These remarks apply chiefly to the day. At night the wearer of tight and rigid foot-coverings reaps the recompense of his imprudence by sufferings which are wholly needless. When the body is placed in the recumbent posture the force of the blood-pump—the heart—is economised, and the current grows both weaker and slower. The necessary result of this change is, that there seems to be a tendency to coldness in the state of sleep,

and those who suffer from cold feet seek to remedy this discomfort by heaping clothes on their extremities. They forget that the way to maintain animal heat is to incite the system to work. By judiciously and *rapidly* bathing the feet in cold or cool water before going to bed, and then rubbing them so as to promote the circulation, the blood-supply of the extremities may be augmented; and by the avoidance of heavy and, what is called, warm bedclothes on the feet the force of the circulation in the organs will be maintained far more effectually, and with incomparably greater comfort, than when the coverings are doubled and trebled, and even supplemented by artificial heat because the feet are cold! There are, of course, cases in which a different method of procedure must be adopted; but when the seemingly healthy resort to heavy and hard foot-coverings by day and artificial foot-warmers by night, it should be under express medical advice. The normal ways of procuring warmth are the best—namely, nutrition and work.

NEUROSAL PALPITATION.

At the November meeting of the Medical Society of the College of Physicians in Ireland, Dr. Bernard made a communication on a case of Neurosal Palpitation which he had brought before the members of the Society last session. The patient was exhibited in the early part of the present year, and suffered from protrusion of the eyeballs, extreme palpitation, and some enlargement of the middle lobe of the thyroid body. Indeed, were it not that the latter sign was not well marked, the case might have been regarded as an example of exophthalmic goitre. The patient took a voyage to America, and returned quite free from all his former troubles, and with a pulse of 74 beats per minute. At the same meeting a case of Pericarditis was detailed by Dr. Walter Smith, Vice-President of the College, in which the "paradoxical pulse" had occurred.

STIMULANTS IN WORKHOUSES.

WE have another contribution to the elucidation of the difficult question of the therapeutical use of alcohol in workhouses in a report by Mr. Anderson, to the guardians of West Derby, Liverpool, in reference to the patients in Walton workhouse. At the urgent request of many guardians, supported by statistical representations from other unions, Mr. Anderson resolved in the treatment of hospital cases to give stimulants only in the most urgent and severe cases. During eight weeks ending November sixty-three patients died, with an outlay for stimulants of £31 17s. 7d., whereas in 1879, only twenty-three died with a consumption of alcohol represented by £122 7s. 8½d., and in 1878, twenty-two died with an outlay of £85 19s. 0d. Mr. Anderson thinks these figures show the impolicy of the treatment, and, in particular, expresses his opinion that to withhold stimulants from the sick poor in Liverpool in illness is to prolong their convalescence, owing to the impoverished state in which the majority come into the workhouse. Undoubtedly they must require sustaining and feeding treatment. And Mr. Anderson's figures may have some interest. But we cannot attach much importance to them, in the absence of many more details than are covered by a mere statement of the number of deaths and the bill for alcohol. This is obviously so bare a statement as to be without scientific value. What were the cases? and how far do the cases of one year bear comparison with those of another? what was the state of the weather? what of the employment of the people? what was the prevalent character of disease in Liverpool generally at each period? what food was given in the place of stimulants? &c. &c. These questions and others must be answered before any comparison can be trusted. Mr. Anderson's own figures show that he is hanging too much on this

one peg of stimulants. For example, between the years 1878-79 there was a difference of only one death, but there was a difference of £37 in the bill for alcohol. There was one death less in the year 1878, with an expenditure of £85 19s., than in the year 1879, with an expenditure of £122! Clearly we have something more to learn about the mortality in the Walton workhouse than is told us by the bill for stimulants.

A SPINAL ROOT OF THE OPTIC NERVE.

STILLING of Strasburg showed preparations to the International Ophthalmological Congress at Mailand, in September last, which he believes demonstrate the existence of a spinal root of the optic nerve, which brings the retina into direct connexion with the medulla. This root passes from the external corpus geniculatum, in a winding course, deep between the bundles of the crus cerebri, and can be traced into the pons; and it appears to course down in the direction of the medulla, although its further progress cannot be demonstrated. The existence of this branch is interesting on account of the light it throws on certain physiological relations between the medulla and the retina, and may constitute the hitherto undiscovered link between certain diseases of the spinal cord and of the optic nerve.

DEATHS IN POLICE STATIONS.—HOSPITAL-CELLS.

THE subject of deaths in police stations needs to be discussed in a new fashion from a fresh standpoint. While these occurrences are all made the ground of graceless imputations on the humanity of the Force, they cannot be expected to command the attention the subject demands. Everybody knows that, with rare exceptions, the officers of justice in this country are full of feeling, and the authorities under whom they serve would incomparably rather do right than wrong, and save life than squander it, if only the system extant rendered the best modes of procedure possible. As it is, the cells at the most favourably constructed stations are placed in communication with the inspector's office, so that any prisoner can call for the assistance he or she feels to be necessary, and each cell is visited every hour; moreover, there is no reluctance to summon the surgeon in cases of doubt. What more can be desired? It might, indeed, be possible to build station-cells like the oakum-cages in prisons, open to view on one side, and to keep a patrol walking up and down, but he would probably have so much to do under circumstances which formed a standing invitation to malingers that the system does not look promising. Might it not be worth while to consider the suggestion we have repeatedly made in these columns, hitherto without, so far as we are aware, attracting the slightest attention? It is this: Set apart a strong room at each of the stations for use as an infirmary. Fit and furnish this apartment judiciously and place it in charge of proper attendants. Let every case of real or supposed drunkenness, insensibility, or any sort of illness be placed therein. Let a medical man be called in at once to each of such cases, and whatever may be necessary done for the safety of the prisoner. Then let the charges for medicine, advice, and attendance be added to the amount of "costs" in every conviction or committal, or recovered, by a summary proceeding before the magistrate, from the prisoner or his friends. If the case proved to be one of simple drunkenness the expense incurred would be justly added to the fine. If it turned out to be one of illness the sufferer or his friends would willingly defray the cost of prompt assistance. The hospital-ward of a police-station might thus be a place where prisoners were under perpetual observation and where they received proper treatment, and the department might be easily made, in part if not wholly, self-supporting. Taking one police-station with another throughout the metropolis, or any large and popular district

where some provision of the kind is most urgently needed, we believe the arrangement would be found to work without burden to the ratepayers, and prove entirely satisfactory. It would be something to know that the scheme, which we have often urged on the consideration of the authorities, had at last been seriously entertained.

ARMY MEDICAL DEPARTMENT.

THE Secretary of State for War has decided to abolish the appointment of Head of the Statistical Branch, Whitehall-yard, vacant by the death of Deputy Surgeon-General B. Tydd. For the future the Sanitary and Statistical Branches of the War Office will be amalgamated and presided over by Deputy Surgeon-General J. Irvine, the present Head of the Sanitary Department. This arrangement is certainly an economical one for the State, but a loss to medical officers of the army of a Deputy Surgeon-General's appointment. It will remain to be seen whether the statistics and sanitary work in connexion with the army suffer in consequence of the reduced staff at head-quarters.

ANOTHER PAY HOSPITAL.

OUR advertising columns give particulars of a praiseworthy experiment to provide a hospital where middle-class people and well-to-do artisans may be supplied with the advantages of hospital treatment, with the comfort and privacy of home on comparatively independent terms. The institution, Bolingbroke House Pay Hospital, is situated in Wandsworth Common, has a committee of management, and a medical staff of six gentlemen, from which patients may select their own adviser. Such experiments deserve to succeed. It is considered that such hospitals can only be made to pay by an average payment per week per patient of two guineas.

CHIANTURPENTINE IN CANCER.

At the meeting of the Medical Committee of the Middlesex Hospital on Nov. 20th, 1880, it was resolved that no more Chianturpentine should be ordered for the treatment of cancer, as, after a prolonged and careful trial, it had been found that its results were perfectly negative.

By the coolness and courage of his coachman, Dr. Rawdon Macnamara, of Dublin, was last week saved from an accident which might have been attended with very serious consequences. It appears that on the 20th instant Dr. Macnamara was returning home after paying his professional visits, and his horses, eager to reach their comfortable stable, got into a pace which required checking with a vigorous hand. The reins at length parted under the strain, and the animals, thus freed from control, dashed along Stephen's-green at a furious rate, to the imminent danger of the occupants of the carriage. In this emergency the coachman bravely and adroitly balanced himself upon the pole of the vehicle and managed to seize the broken ends of the reins, and thus prevent an otherwise inevitable catastrophe.

A SERIES of lectures is to be delivered at the National Hospital for the Paralyzed and Epileptic, Queen-square, during the present winter by the members of the medical staff. The names of the lecturers will be announced in the usual way. The first three lectures of the series will be given on Thursdays, Dec. 2nd, 9th, and 16th, at 5 P.M.

THE Lord Mayor, at the request of a deputation from the committee of the St. John Ambulance Association which waited upon him on Monday last, has consented to convene a meeting at the Mansion House after Christmas, with the view of promoting the objects of the Association.

IN reference to the spread of farcy and glanders among horses in London, Dr. Brewer, chairman of the Special Purposes and Sanitary Committee of the Metropolitan Board of Works, has called attention to faults in the construction of the drinking troughs erected about the streets of the metropolis. Not only are horses and cattle allowed to drink indiscriminately at these troughs, but children have been seen to quench their thirst at them. Hence an obvious source of danger, which it would be well to have removed by a flushing system or some other practicable measure.

THE formation of a Provident Dispensary in connexion with the Halifax Infirmary has been decided upon, and a committee has been nominated to carry out the proposition. We understand that the medical staff of the infirmary are not favourable to the project.

AT a meeting convened at Colchester to support the repeal of the Contagious Diseases Acts, a counter-proposition approving of the measures was carried almost unanimously. The meeting, however, appears to have broken up in disorder.

THE successor to Professor Wilms in the post of chief surgeon at Bethany Hospital in Berlin is stated to be Professor Rose of Zurich, who for some years acted as assistant to the deceased surgeon.

SURGEON-GENERAL FREDERICK FREEMAN ALLEN, M.D., C.B., has been appointed Honorary Physician to Her Majesty, rendered vacant by the death of Deputy Inspector-General Goodeve.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Pontardawe (Rural Sanitary District).—The Pontardawe rural sanitary district is situated at the upper part of the Swansea valley, and is drained by the river Tawe and its tributaries. Early in the present year the Local Government Board held it desirable to direct an inquiry to be made into the prevalence of enteric fever in and general sanitary condition of the district, and Dr. Parsons was instructed to undertake the duty. His account of the district shows that although in the inhabited localities the slovenly and unwholesome characteristics of the older Welsh mining districts still preponderate, a gradual amendment of the sanitary condition of the villages has been taking place in recent years, and may be anticipated to continue under existing arrangements for their sanitary administration.

As to the prevalence of enteric fever in the district, Dr. Parsons shows that two sets of conditions combine to bring about this prevalence. First, there are the local and still unamended conditions causing fouling of air, soil, and water with excremental matters, and which are known to favour the existence of enteric fever; and, second, there is the liability of the district to infection with the disease from the neighbouring town of Swansea. Of the operation of both these sets of conditions Dr. Parsons furnishes most interesting illustrations, and particularly he gives an instructive account, illustrated by maps, of an outbreak of enteric fever at Ystalyfera in 1879, which had been carefully worked out by the medical officer of health, Dr. Thomas, and which, originating from an imported case from Swansea, was determined by the pollution of a source of water-supply to which the excremental discharges of this patient had accidentally got access.

Stourbridge (Registration District).—This report, also from the pen of Dr. Parsons, is one of a class which there seems an increasing tendency on the part of the Medical Department to favour. It refers to the sanitary condition of a whole

registration district, which contains, in addition to three urban sanitary districts, a large rural sanitary district. The entire district has an area of 16,116 acres, a population (1871) of 73,386, and houses to the number (1871) of 15,460. The attention of the Local Government Board has been directed to it (not for the first time) by the recent great prevalence of scarlet fever in the district, its undue general mortality, and the excessive mortality of certain infectious diseases, particularly small-pox and scarlet fever, within it. The following passage from the report shows the apparent relation between the fatality of scarlet fever and the general death-rate of the Stourbridge registration district:—"There appears to be some relation between the degree of fatality of scarlet fever and those sanitary and social conditions upon which the amount of the general death-rate depends. With the exception of the Quarry Bank district, the death-rate from scarlet fever follows pretty closely that from all causes; the Worcestershire division of the rural district, the sanitary condition of the principal places in which will be described in this report, figuring high both in regard of total death-rate and of death-rate from scarlet fever. It can hardly be doubted that the pollution with filth of the water which people drink, and of the air which they breathe, must tend to increase the virulence of an outbreak of scarlet fever, both by affording opportunities for the conveyance of the infective matter from person to person, and by placing those who are attacked under circumstances less favourable to recovery. One condition especially would seem eminently favourable to the conveyance of the infection from case to case—viz., that in most parts of the Registration District the liquid refuse of houses, so far as it is conveyed away at all, runs down open channels, often of very rough construction, very frequently for a considerable distance, passing in its way other houses, and trickling down the gutters, or stagnating upon the surface, of the public streets. It is known that the poison of scarlet fever is given off copiously from the patient's body in the scales thrown off from the skin and in the liquid excretions; it would therefore necessarily be largely present in the washing water and other foul liquids which find their way down these channels, giving off emanations which the passers-by cannot avoid inhaling."

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham.—The report of the medical officer of health (Dr. Alfred Hill), for the summer quarter ending October 2nd, shows that the birth-rate of the town during the quarter was 36·2 per 1000 population, as compared with 40·2 and 38·3 in the third quarters of 1878 and 1879; and the death-rate 21·65, as compared with 22·25, 25·90, and 16·35 in the third quarters of 1877, 1878, and 1879 respectively. The increase on the summer quarter of 1879 is entirely accounted for by the much greater fatality of diarrhoea during the quarter of the present year, and on this Dr. Hill observes: "There can be no doubt that the higher temperature was the grand predisposing cause of the increase of infantile diarrhoea, while there can be scarcely less doubt that improper food and feeding constituted the principal exciting cause."

Bristol.—Mr. Davies in his report for the third quarter of the year states that the rate of mortality in the city was 17·9 per 1000 population, as compared with 16·5 during the corresponding period of 1879. The birth-rate was 33·4 per 1000 population, as compared with 35·4 in the third quarter of 1879—a falling off which he attributes to the long-continued commercial depression, and possibly an increasing emigration of the working classes to more promising fields of employment. 2·4 per cent. of the deaths which occurred during the quarter were registered without a medical certificate or a legal inquiry regarding the cause of death. "Such a fact," he observes, "is a disgrace to a civilised community, as it leaves an open door for crimes at which humanity shudders."

THE NOTIFICATION OF INFECTIOUS DISEASES.

The chance-medley sort of private legislation which is going on in the matter of notification of infectious diseases is aptly illustrated by the provisions in this respect which received the assent of Parliament last session, in the Huddersfield Improvement Act, 1880. In an Act of 1876, Huddersfield obtained powers to require the notification of certain infectious diseases from medical men residing in the borough; but the provisions of the Act had been so imperfectly considered, that from the first they proved unworkable. If we mistake not, a fee of 2s. 6d. was to be given to

the medical man for each notification, and the duty was imposed upon the medical man to report each case. The Corporation had not counted the cost, and were aghast at what they had brought upon themselves, and so they proceeded forthwith to explain away the literal meaning of the Act by stating that they meant (the phraseology of the Act notwithstanding) only the *first* case of infectious disease occurring in a house to be notified, not subsequent cases, should a series of cases follow. Hence arose difficulties with the medical practitioners which ought to have been foreseen and provided against. But the Corporation in its new Act appears to have gone out of its way to make the provisions for the notification of disease as insulting to the medical profession as they could well be, and the insult is not the less from the slovenliness and want of foresight with which the provisions have been drafted. The medical practitioner called in to a case of infectious disease *must*, it is provided, *forthwith* notify this to the Corporation either at their Sanitary Office, or if the same be closed, at their police station; for doing this he is to receive a fee of *one shilling* (!), and such fee is to apply only to *one* certificate by the same practitioner in regard to the same disease, from the same building, for a period of thirty days; ("but only one such certificate need be given, and only one such fee is payable within an interval of thirty days, to the same medical practitioner, in respect of the same disease occurring in the same building.") Nor is this all: the Corporation, which has provided for such magnificent remuneration (*under a penalty of £10 for neglect*), in a circular issued to medical men, express a hope that they will loyally assist the Corporation in carrying out the new provisions, and state that it will be esteemed a favour if, "in addition to the particulars required by the section, the medical practitioner would also give such information as he is able to give upon other points on which queries are appended in the printed forms." The queries referred to are six in number, and the object of the form as it stands appears to be to induce medical men to relieve the medical officer of health as much as possible of his duties, and enable the Corporation to obtain the services of that officer at a cheaper rate! It might be thought that the Corporation of an important town could not well descend to greater depths of meanness and narrow-mindedness in the performance of their public duties than is here shown. But there is a greater depth still. *The medical man is expected to pay the cost of sending, whether by the post or otherwise, the notification to the Corporation offices!* Add that while the provisions contemplate that notifications of infectious disease will be sent at all hours day and night, it does not contemplate that the sanitary officers, for whose immediate information they are sent, shall be available to make use of them for more than a few hours during the day, and it proposes to devolve part of its duties of sanitary administration upon the police. In other words, the provisions betray as little knowledge of what is required to give due practical effect to notifications of disease as they do of the courtesy which is due to a learned profession.

Surely it is time that this chance-medley private legislation in regard to the notification of diseases should cease, and that a general measure should be promoted on the subject by the Government.

THE METROPOLITAN WATER-SUPPLY.

The delegates of the Vestries and District Boards of Works of the Metropolis, at a recent meeting, agreed to a memorial to the Home Secretary, of which the following are the principal points:—"The memorialists are anxious that the recommendations by the Committee of the House of Commons, Session 2, 1880, should be carried out with the least possible delay, and agree that it is expedient that the supply of water to the metropolis should be placed under the control of some public body which shall represent the interests and command the confidence of the water consumers. That, in the absence of any single municipal body to which these functions could be committed, and until the same is created, they concur in the desire that a water authority of a representative character should be constituted on a basis no less representative than that of the London School Board, and that a Bill having that object should be introduced at the earliest possible moment. They do not concur that such body should be filtrated from the Metropolitan Board and the City Corporation, but should be absolutely representative of the ratepayers direct, including representatives of the districts supplied by the water com-

panies. They desire to represent that such body or trust should be authorised to acquire the undertakings of the existing companies, if the same or any of them can be acquired upon fair and reasonable terms; but, failing such arrangement, their powers should extend to the introduction of an independent water-supply, with the requisite authority to raise capital, to impose rates, and to control, in the interest of the ratepayers, this essential necessary of life." At the meeting of the Metropolitan Board of Works on the 12th inst. it was stated that at the first conference of delegates from Vestries and District Boards of Works in the Metropolitan (over thirty in number) on the metropolitan water-supply, not more than ten or eleven of those bodies were represented.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES IN DUBLIN.

At a meeting of the Corporation of Dublin held last Monday, the Lord Mayor referred to the deputation of medical gentlemen who had waited on him the previous week for the purpose of showing the necessity of introducing an Act of Parliament making it compulsory to notify to the sanitary authority in Dublin the presence of any infectious disease in any house. The principal difficulty, he thought, would be met with amongst the poorer classes; but it was also most necessary that such notification should be made when infectious disease existed in any house of the wealthier classes. He considered it would be advisable to introduce a Permissive Act, applicable to the whole of Ireland, giving the Local Government Board power to direct the clauses to be carried out in those districts when it appeared desirable. As regarded the details there was some difference of opinion. Some considered that the notification should be made by the medical attendant, while others were of opinion that the duty should be thrown on the householder; but a middle course was suggested—namely, that the medical practitioner should hand a printed form to the inmates of the house, informing them of the infectious disease and of the requirements of the law; but throwing the responsibility of making the notification on the householder. His lordship suggested that a deputation of the Council should wait on the Chief Secretary for Ireland, and ask him to introduce a Permissive Bill applicable to all Ireland, or whether the Government would support a Bill introduced by a private member. A resolution to this effect was adopted, and it was determined that various suggestions should be prepared to lay before the Chief Secretary, as to the mode of carrying out the proposal; with power to consult with the medical deputation which waited on the Lord Mayor, with a view to joint action, and if considered desirable a joint deputation.

SCARLET FEVER IN DUNDEE.

We are favoured with the following particulars respecting the recent outbreak of scarlet fever in Dundee. Between the 5th October and the 9th November 72 cases were reported to, or ascertained to exist in the town by, the Sanitary Authority. About the 22nd October a number of cases occurred simultaneously in a limited area at the south end of the town, and it was discovered that the families in which these cases occurred obtained their milk from the same dairy. Inquiry at this dairy elicited the following facts. About the 10th October a maid employed in the dairy visited her father's home, where scarlet fever had recently been, and removed therefrom some articles of clothing for her own use. A week after she again visited the same house, and on the 22nd October the dairyman's daughter was seized with an attack of scarlet fever. By the 31st October a number of the dairyman's customers were ill of scarlet fever, 15 cases having occurred in eight different homes. The Sanitary Authority at once adopted proper measures, and now the dairy in question is entirely free from infection.

The more attention is given to the limitation of infectious diseases the more difficulties seem to multiply. At a recent meeting of the London School Board attention was directed to the fact that a care-taker of a school in Lambeth, having a family of seven children, and occupying a house containing two rooms (!) only, communicating with the school, had scarlet fever among the family. Two courses to be followed here suggest themselves (neither satisfactory)—namely, to appoint care-takers without families of young children, or to detach the care-taker's house from the school.

Great Baddow, in Essex, has been suffering from both scarlet fever and diphtheria. The scarlet fever cases have not been numerous, nor has the disease been fatal. The diphtheria cases have been more numerous, and there have been several deaths among them. In one instance, we understand that a man who lost two children (by a former wife) from diphtheria in 1859, lost in this later outbreak of the disease three children—affording an interesting illustration of family predisposition to fatality from this disease. We trust that the Sanitary Authority will soon give to the public the report of their medical officer of health (Dr. Arthur Downes) on this concurrence of two infective diseases. Both diseases, according to our latest information, have now ceased in the village.

The Axbridge Urban Sanitary Authority having been recently asked by the Board of Guardians if they would receive patients sent by the Guardians into their statutory hospital, replied that they would be prepared to do so if the Guardians made arrangements for and provided all necessary medicine, medical attendance, beer, wine, spirits, and other requisites, and the cost of internment of any patient sent by the Guardians who might die in the hospital. We infer from this that the hospital in question is merely a building in which patients can be placed, and having none of the appliances proper for a hospital. The Guardians naturally decline to accede to terms so preposterous.

Dr. Hughes, the medical officer of health for Cardigan, has presented a special report to the Urban Sanitary Authority on a recent outbreak of scarlet fever in his district. It refers to 199 patients, of whom 101 were under five years of age. He found it impracticable to induce the parents of young children to isolate their children in hospital, and his efforts were checkmated by the popular belief that everyone must have the fever at one time or other, and the earlier the disease was "had over" the better.

The rains must, indeed, have been heavy of late, since a dealer in milk, summoned before the magistrates for diluting the commodity he sold with 20 per cent. of water, explained that rain must have found its way into the fluid during delivery, and so prejudiced his character. Sad to say, the magistrates refused to accept this explanation of the matter, and inflicted a fine of 40s. and costs.

Typhoid fever has broken out at Beer (Somerset), and it has been found necessary to take immediate steps to improve the sanitary condition of the village—in other words, to lock the stable door after the horse has been stolen.

Dr. Partridge, the medical officer of health for Stroud, was recently a petitioner to the Sanitary Authority of which he is the medical officer against a nuisance from smoke caused by a factory.

No. 7 of the Charity Reform Papers deals with the "Dwellings of the Poor and Present Legislation respecting them." It is a most useful and instructive paper.

Mr. Ashenden, the medical officer of health for Hastings, reports a death-rate of 14·37 per thousand in that town during the third quarter of the year.

The Limehouse Vestry is seriously considering the question of erecting a mortuary.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality, which had [been unusually stationary during the four preceding weeks, showed a decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4828 births and 3044 deaths were registered last week. The births were 357, and the deaths 231 below the average weekly numbers during 1879. The deaths showed a decline of 235 from the number returned in the previous week; and the annual death-rate per 1000, which had only varied from 22·6 to 22·8 in the four preceding weeks, declined last week to 21·2, a lower rate than has prevailed in any week since the middle of July. The lowest death-rates in the twenty towns last week were 16·1 in Birmingham, 16·4 in Hull, 18·8 in Sheffield, and 19·0 in Leeds. The rates in the other towns ranged upwards to 23·9 in Bristol, 24·0 in Oldham, 24·3 in Norwich, and 25·0 in Liver-

pool. During the first seven weeks of the current quarter the death-rate in these twenty towns averaged 22.1 per 1000, against 21.8 in the corresponding periods of the four years 1876-9.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 428 and 474 in the two preceding weeks, declined to 367 last week, a lower number than has been returned in any previous week of this year; they included 138 from scarlet fever, 58 from measles, and 55 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2.6 per 1000 in the twenty towns, and ranged from 0.7 and 1.0 in Plymouth and Hull, to 4.3 and 6.3 in Norwich and Sunderland. The fatal cases of scarlet fever, which had been 150 and 163 in the two previous weeks, declined to 138 last week, and showed the largest proportional fatality in Sunderland, Oldham, Norwich, and Salford. Whooping-cough was most fatal in Sunderland. The highest death-rates from enteric fever occurred in Portsmouth, Norwich, and Newcastle-upon-Tyne. The 19 deaths from diphtheria in the twenty towns included 12 in London, and 2 both in Liverpool and Portsmouth. Small-pox caused 10 more deaths in London, against 7 and 17 in the two previous weeks; but no death from this disease was recorded in any of the nineteen provincial towns.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 421 in the ten preceding weeks, fell to 332 last week, and were no less than 112 below the corrected average number in the corresponding week of the last ten years; 195 resulted from bronchitis, and 97 from pneumonia. The annual death-rate from lung diseases was equal to 4.7 per 1000 in London, 7.5 in Liverpool, and 7.3 in Salford.

In the twenty towns last week 82 deaths were registered without the production of the certificate of a registered medical practitioner or the holding of an inquest; these were equal to 2.7 per cent. of the total deaths. The proportion of uncertified causes of death did not exceed 1.3 per cent. in London, whereas it averaged 4.1 per cent. in the nineteen provincial towns. No uncertified deaths were registered in Leeds, Portsmouth, Brighton, or Plymouth, while the largest proportions occurred in Norwich, Oldham, Hull, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week was equal to 20.9 per 1000, against 24.2 and 23.8 in the two preceding weeks, and was 0.3 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 13.6 and 19.4 in Perth and Glasgow, to 23.4 and 29.5 in Paisley and Greenock. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 115 and 125 in the two previous weeks, declined to 93 last week; they included 45 from scarlet fever, 13 from whooping-cough, 12 from fever, 10 from diarrhoea, 7 from diphtheria, 6 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 3.7 per 1000 in the eight towns, and exceeded by 1.1 the average rate from the same diseases in the twenty English towns. In the eight Scotch towns the zymotic death-rate ranged from 0.5 and 1.7 in Aberdeen and Dundee, to 5.7 and 5.8 in Edinburgh and Perth. The high zymotic death-rate in Edinburgh was again due to the epidemic prevalence of scarlet fever. The fatal cases of this disease, which had been 47 and 53 in the two preceding weeks, declined last week to 45, of which 21 occurred in Edinburgh, 16 in Glasgow, and 6 in Leith. The deaths from whooping-cough, fever, diarrhoea, and measles also showed a decline from recent weekly numbers. Of the 12 deaths referred to fever (mainly enteric), 7 were recorded in Glasgow, 2 in Paisley, and one each in Edinburgh, Dundee, and Greenock. The 7 from diphtheria included 4 in Glasgow, 2 in Greenock, and one in Edinburgh. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had steadily increased from 120 to 154 in the four preceding weeks, declined to 137 last week. The annual death-rate from these lung diseases last week was equal to 5.5 per 1000 in the eight Scotch towns, against 4.8 in London; the highest death-rates last week from these diseases in the Scotch towns occurred in Greenock and Dundee.

HEALTH OF DUBLIN.

The death-rate in Dublin showed a slight decline from the high rates that have recently prevailed. The annual rate of mortality from all causes in the city, which had been equal to 34.4 and 39.6 in the two preceding weeks, declined to 33.3 last week. During the past seven weeks of the current quarter, however, the death-rate in the city has averaged 34.4 per 1000, against 21.3 in London, and 22.4 in Edinburgh. The 201 deaths in Dublin last week were 38 less than the exceptionally high number in the previous week, and included 25, or 12 per cent., which were referred to the seven principal zymotic diseases, showing a further decline from recent weekly numbers; 10 resulted from fever (including typhus, enteric, and simple), 5 from scarlet fever, 4 from whooping-cough, 3 from diarrhoea, and one each from small-pox, measles, and diphtheria. The annual death-rate from these zymotic diseases was equal to 4.1 per 1000 in Dublin last week, against 2.6 in London, and 5.7 in Edinburgh. The deaths referred to fever, which had been 9 and 7 in the two previous weeks, rose to 10 last week; whereas the fatal cases of scarlet fever declined to 5 from numbers which decreased from 16 to 6 in the four preceding weeks. The deaths from whooping-cough and diarrhoea also showed a decline from recent weekly numbers. The excessive death-rate from fever (mainly enteric) is the most unsatisfactory feature in last week's zymotic fatality. The deaths of infants in the city last week were fewer than in any week since the beginning of August, but still showed an excessive rate. The deaths of elderly persons were but 7 less than those returned in the previous week.

VACCINATION AND SMALL-POX IN PARIS, DUBLIN, AND LONDON.

Small-pox was fatally epidemic in Paris and in Dublin during the first nine months of this year; and London during this period was never quite free from the fatal prevalence of this disease. The annual death-rate from small-pox during the nine months ending September last was equal to 1.35 per 1000 persons living in Paris and to 1.07 in Dublin, while the rate in London did not exceed 0.12 per 1000. Unfortunately the mortality statistics for these three cities are not uniform, but the published facts in the several official returns afford a means for estimating the amount and quality of infant vaccination. One of the most indubitable effects of vaccination upon small-pox mortality is the marked decline in the proportion of fatal cases occurring among children under five years of age. In the year 1847 no less than 73.7 per cent. of the total deaths from small-pox in England and Wales were of children under five years of age; whereas, since that date, under the influence of compulsory vaccination, the proportion of fatal cases occurring among children of these ages has steadily declined, and in 1878 it did not exceed 25.5 per cent. During these thirty-two years the proportion of fatal cases occurring under one year of age has declined from 25.4 to 12.0 per cent.; between one and two years of age, from 19.1 to 3.4 per cent.; and between two and five years, from 29.2 to 10.1 per cent. It is impossible to attribute this change in the proportional age distribution of fatal cases of small-pox to any other cause than the effect of more general vaccination. We may therefore approximately estimate the proportional extent and efficiency of vaccination in Paris, Dublin, and London, by comparing the relative amounts of infant mortality from small-pox in these three cities. In Paris during the first nine months of this year 26.4 per cent. of the total deaths from small-pox were of children under five years of age; in Dublin the proportion was no less than 34.5 per cent., and in London to 29.2 per cent. Judged by these figures, the amount and quality of infant vaccination differs little in London and Paris, whereas considerably greater neglect of vaccination appears to prevail in Dublin.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

FATALITY OF SMALL-POX IN LONDON.

The prevalence and fatality of small-pox in London have shown a marked increase during the past few weeks, threatening a revival of the epidemic which commenced in 1876, and has never since died out. The deaths from this disease within registration London, which were but 56 and

75 in 1874 and 1875, rose to 735 and 2544 in 1876 and 1877, and declined again to 1416 and 458 in 1878 and 1879. In the first three-quarters of this year the fatal cases were respectively 122, 144, and 49; while 54 were recorded during the first seven weeks of the current quarter. They averaged 4 per week in September, 5 in October, and were 7, 17, and 10 respectively in the first three weeks of November. Since the end of September there has been a distinct and severe outbreak of small-pox in East London, notably in Bethnal-green; indeed, of the 54 fatal cases recorded during the past seven weeks no less than 31 were of residents of East London. The immunity from fatal small-pox which the nineteen large provincial towns have enjoyed since the beginning of 1878 forms a striking contrast to the continued prevalence of the disease in London; the recorded deaths from small-pox in the nineteen provincial towns, which have an aggregate population rather larger than that of London, have been but 28 since 1st January, 1878, while in London they have numbered no less than 2243.

The returns furnished by the Metropolitan Asylums Board Hospitals afford evidence strongly corroborative of the recent serious outbreak in East London. The number of small-pox patients in these hospitals, which had almost steadily declined from 237 in the middle June to 77 on Oct. 23rd, rose successively to 105, 114, and 118 at the end of the three succeeding weeks. During the week ending last Saturday they further rose to 182, a higher number than have been under treatment at one time since the middle of July. The number of new cases of small-pox admitted to these hospitals, which had been 38, 24, and 31 in the last three preceding weeks, jumped up to 99 last week. So large a number of admissions has not occurred in any week since February, 1879. Of 135 new cases admitted to these hospitals during the ten days ending 21st, 27 came from Bethnal-green, 20 from St. George's-in-the-East, 20 from Hackney, 13 from Stepney, 10 from Mile-end Old-town, 8 from St. Saviour's, Southwark, 5 from Shoreditch, and 4 from Whitechapel. The outbreak, therefore, is distinctly one in East London, and it is evident that it has already assumed large proportions; its control must now mainly depend upon the successful efforts of the local sanitary authorities to utilise the hospitals of the Metropolitan Asylums Board for isolation purposes, as they have provided no hospitals of their own. It would be interesting to know what steps are being taken to secure the vaccination of the considerable proportion of unvaccinated, or imperfectly vaccinated, children in these Eastern metropolitan districts.

INFANT MORTALITY IN AUSTRALIA.

The Registrar-General of New South Wales has recently issued the twenty-fourth annual report on the Vital Statistics of the Colony, which bears evidence of the continued growth of its population, estimated at the end of 1879 at 734,282 persons. The increase of population during the year was rather more than 40,000, and nearly equal to 6 percent. upon the population of the preceding year. The report before us does credit to the printer as well as the compiler, and is full of interest as a record of the rapid progress of the colony. Viewed, however, as a contribution to vital statistics, it is in some respects open to criticism, and contains some faulty conclusions which have to be guarded against. Infant mortality in the Australian colonies is an interesting subject, and we were disappointed to find it treated in an unscientific manner. The report commits the fault of attempting to measure infant mortality by the proportion of deaths under five years of age to total deaths, with the inevitable result of leading to fallacious conclusions. We are told: "It will be seen that the rate of infant mortality is lower in Sydney than in the suburbs or country districts." Such a fact would be without a parallel in vital statistics, and should have suggested some source of error. The proportion of deaths of children to total deaths in populations differently constituted as to age distribution can never be usefully compared as evidence of infant mortality; and this source of error is most marked in new colonies, where populations are abnormally constituted as to age distribution. The true state of the matter as to infant mortality in New South Wales is exactly the reverse of what the Registrar-General has stated it to be. We have been at the pains to calculate the rate of infant mortality in the different subdivisions of the colony, measured by the proportion of deaths under one year of age to births registered. These facts are to be found in the report, but no use has

been made of them for calculating a true rate of infant mortality. The proportion of deaths under one year to births averaged 107 per 1000 in the entire colony, while it was equal to 165 in Sydney, and 143 in its suburbs; it did not, however, exceed 88 in the country districts. Infant mortality in Sydney in 1879, therefore, instead of being lower was nearly twice as high as that which prevailed in the country districts. We venture to hope that in future reports this subject will be handled in a more scientific manner. True infant mortality is most satisfactorily measured by the proportion of deaths under one year to births, and the death-rate of children under five years by the proportion of deaths to children living at these ages. It is worthy of comment that the rates of marriages and of births in the colony have pretty steadily declined during recent years. This ought not to be the case in a population which is increasing rapidly by the immigration of young adults, and suggests defective registration; but it seems improbable that registration can be more defective than it was ten years ago.

SANITARY INSPECTION OF SCHOOLS: RUSSIA.

At a meeting of the Society of Medicine, St. Petersburg, on the 12th instant, Professor Andrievsky maintained the necessity for a sanitary inspection of primary schools. He supported his position by the practice followed in Germany and Austria, but especially in Austria. There a medical council is attached to the Ministry of Interior, having the special duty of advising upon the sanitary requirements of schools and school-life, while provincial councils had special inspecting medical officers appointed, for the same purposes, in every city in the empire. The hygienic requirements of the school are prescribed by the Minister—its locality, the disposition of the classes, its lighting, arrangement of the benches, &c. Moreover, the school regulations include a series of provisions for the physical development of the children. At the conclusion of Professor Andrievsky's communication the Society of Medicine resolved to approve the examination of the health of children at their entry into the primary schools and during the course of instruction there, and the advisability of medical opinion being consulted in the formation of educational programmes and the plans of schools.

HEALTH OF CALCUTTA.

Surgeon-Major D. K. McLeod's report on the health of Calcutta for the third quarter of 1880 shows that the temperature of the quarter had been moderate, the rainfall somewhat above the average, the humidity high, and the atmospheric pressure normal. In short, the quarter had been, on the whole, "agreeable and healthy," with "none of those rainless and 'steamy' intervals so unpleasant to sensation, and trying to health." The mortality of the town was below the decennial average, sickness was moderate, and no epidemic of any kind prevailed in the quarter. The deaths from cholera were less than in any of the corresponding quarters during the decade; the deaths from fever were almost unprecedentedly low, and the mortality from bowel-complaints was also at a very low level. Small-pox continued to exhibit few deaths, the deaths from "other causes" alone showing an increase above the decennial mean. Dr. McLeod remarks that arrangements are in good progress for carrying into effect the Vaccination Act of 1880.

DIPHTHERIA IN RUSSIA.

The Red Cross Society of Russia undertook to contribute within a period of six months, in aid of the measures being put in force for the arrest of diphtheria in the province of Poltava, 1,100,000 roubles in money; also to furnish several sanitary detachments. When the six months were expired any further expenditure needed, the epidemic still continuing, was to be borne by the government of the province. The period fixed by the Red Cross Society ended on July 12th, but the epidemic continues, and they have not withdrawn either their representative in the province nor the sanitary detachments they have organised there. Presumably the expense of the further work will fall upon the government of the province.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—

At a meeting of the Council held on the 18th inst., Mr. G. F. Blake was appointed Assistant Librarian in the vacancy caused by the resignation of Mr. J. Alex. Spencer, F.R.C.S.

THE SERVICES.

THE CANDAHAR DESPATCHES.

THE despatches recently published in the *Gazette of India* from Lieutenant-General Sir F. Roberts, V.C., K.C.B., Major-General Primrose, C.S.I., and the late Brigadier-General Brooke, C.B., from Candahar, bring prominently to notice the valuable aid rendered by medical officers on the field. General Roberts reports "Deputy Surgeon-General J. Hanbury, M.B., proved himself to be an efficient administrative officer, and carried on the duties of his responsible office to my entire satisfaction"; and he also brings forward among the names of the officers serving on his personal staff "who have at all times been unremitting in the performance of their duties" that of Surgeon J. F. Williamson, M.B. "General Ross speaks in high terms of officiating Deputy Surgeon-General J. Ekin, M.B." "Brigadier-General Macpherson records that the devotion of the medical officers of the brigade in attending to the wounded under fire was most admirable. He mentions Surgeon-Major S. B. Roe, 92nd Highlanders, Surgeon-Major W. Finden, 2nd Goorkhas, Surgeon E. H. Fenn, R.A., Surgeon H. J. Linton, 24th Punjab Native Infantry, and Surgeon H. Hamilton, M.D., 23rd Pioneers." "Brigadier-General T. D. Baker would wish to mention specially the names of the following officers:—Surgeon-Major G. W. Macnalty, M.D., and Surgeon-Major C. A. Atkins, for the manner in which they attended the wants of the wounded in the fighting line." "Brigadier-General Macgregor brings forward Surgeon-Major G. C. Chesnaye, 4th Goorkhas, and Surgeon-Major E. C. Markey." "Brigadier-General Hugh Gough thanks specially Surgeon-Major R. Lewer." Major-General Primrose mentions "Deputy Surgeon-General J. O'Nial, whose arrangements for the wounded were all that could be desired, and Surgeon-Major B. T. Giraud, A.M.D., whose great attention to the wounded on the field has frequently elicited my admiration; also Surgeon-Major J. Arnott and Surgeon E. W. Kelsall." Brigadier-General Brook, reporting the occurrences of the 20th July, "asks for special consideration of the services of Surgeon J. Macnamara, the medical officer in charge of the column, who was most useful to me."

Surgeon-Majors J. M. Kirkwood, P. J. MacQuaid, and J. M. Beamish are on passage home from India in H.M. troopship *Euphrates*.

The appointment of medical officer to the Royal Military Academy at Woolwich will be vacant in December, Surgeon-Major E. H. Roberts having completed his five years' tour and being under orders to embark for Bengal by one of the next troopships.

ADMIRALTY.—Surgeon Henry B. Guppy to the *Ganges*, for temporary service. Fleet-surgeon Thomas Seccombe, placed upon the retired list.

THE MEDICAL DEPARTMENT.

THE following resolution has been passed by the Government of India. We reprint it from the *Times of India*, received by the last mail:—

It being desirable that the relative authority of the Surgeon-General with the Government of India and the Surgeon-General, Her Majesty's Forces, over the officers of the Indian medical service shall be defined, the Government of India direct—

1. That surgeons of the Indian medical service appointed to Bengal, on arrival at Bombay, shall in accordance with the "instructions" (copy of which will then be furnished to them) send their letters of appointment to the office of the Surgeon-General with the Government of India, by whom they will be at once forwarded to the Military Department. Thereon the officers will be gazetted as having come on a given date on Bengal establishment, and will be formally placed at the disposal of the Commander-in-Chief in India for military duty. Meanwhile, and in anticipation of this formal notification, the officers, in the absence of any order to the contrary, will proceed at once to Allahabad, and on arrival there, will report themselves to the Deputy Surgeon-General of that circle for military duty.

Thenceforward, and until the officer may be withdrawn for other employment, he will be under the authority of the Surgeon-General, Her Majesty's Forces, from whom he will receive all orders of His Excellency the Commander-in-Chief in India for his employment, postings, transfers, &c.

The withdrawal of an officer for civil employment will not be permitted until he has completed two years' actual military duty, and then only provided his services can be spared. Should the interests of the public service, however, very urgently demand his withdrawal before the completion of his two years' course of military duty, an exception may, under the orders of the Governor-General in Council be made, as a very rare and special case, in the above general rule.

2. All officers of the Indian medical service are, subject to the above restriction, eligible for civil duties; yet, however employed, they remain liable at any time to be recalled for military duty. Such recall can only be made by the Government of India in the Military Department. During the whole period of an officer's employment on any other than military duty under the Commander-in-Chief, and until he is formally replaced at His Excellency's disposal, he will be under the authority of the Surgeon-General with the Government of India or of the Local Government under which he may be serving.

3. A minimum establishment for the requirements of the army and for all other sanctioned appointments will always be maintained. This will include the prescribed margin for absentees on furlough or sick leave. Lists of the appointments controlled by the two Surgeon-Generals are annexed; but it will be understood that the army has the first claim on the medical service, and that any officer whose services are required with the army may be placed at the disposal of the Commander-in-Chief.

4. All applications for medical officers required for civil employment should be addressed by local Governments to the Government of India in the Home Department.

5. As the Surgeon-General with the Government of India is the actual administrative head of the Indian medical service, and should, therefore, have the means of keeping an accurate record of the services of all officers belonging to it, such returns and reports, including confidential reports, furlough statements, &c., as are considered necessary for this purpose by the Military Department will, as regards officers under the orders of the Commander-in-Chief, be furnished to the head of the department by the Surgeon-General, Her Majesty's Forces.

Application for furlough of officers under the Commander-in-Chief will be forwarded by the Surgeon-General, Her Majesty's Forces, through the Surgeon-General with the Government of India, so that all such applications may be dealt with for the service as a whole; and all such officers while on furlough or leave will remain on the list of the Surgeon-General, Her Majesty's Forces.

APPENDIX.—Lists of appointments referred to in paragraph 3.—Under Surgeon-General with the Government of India: All medical officers in civil employ; surgeon to His Excellency the Viceroy; principal medical storekeeper; medical storekeepers; medical officer, Lawrence Military Asylum, Sanawur. Under Surgeon-General, Her Majesty's Forces: Deputy Surgeons-General in military employ, 5; secretary to Surgeon-General, 1; surgeon to His Excellency the Commander-in-Chief, 1; garrison surgeons, 3; Sappers and Miners, 1; 19 Bengal Cavalry Regiments, 19; 45 Native Infantry Regiments, 45; 4 Goorkha Regiments, 4; Punjab Frontier Force, 17 (viz., 5 Cavalry—Guides 1, Sikh 4; 6 Infantry—Punjab Infantry 5, Goorkhas 1); Doaba outposts, 1; Central India Horse,¹ 2; Malwa Bheel Corps,¹ 1; Bhopal Battalion,¹ 1; Deolee Irregular Force,² 1; Erinpoora Irregular Force,² 1; Meywar Bheel Corps,² 1; Mhairwarra Battalion,²³ 1.

¹ Civil corps—Administered by Deputy Surgeon-General, Kamptee Circle of Madras Presidency.

² Civil corps—Will be administered by the Superintendent-General of Dispensaries, Rajputana.

³ Under medical charge of the Civil Surgeon, Ajmere.

THE members of the medical profession of Portsmouth have presented a testimonial to Mr. G. Turner, late medical officer of health for the borough, on his leaving to fulfil a like position at Bishop Stortford, Herts. The subscription was limited to one guinea, and there were thirty-seven subscribers.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF GENU VALGUM.

To the Editor of THE LANCET.

SIR,—Mr. Parker objects to your report of his observations at the Royal Medical and Chirurgical Society on November 9th, and having made his corrections he discusses over again my communication to the Society. I must therefore ask you kindly to allow me space for a rejoinder.

Mr. Parker has somewhat misunderstood my paper. I will not, however, discuss it now; but will touch on three points of Mr. Parker's letter. First, as to the length of time required to carry out the treatment. Three casts were shown at the meeting. No. 1 was taken from a girl, sixteen years of age, in whom the inner malleolus was eleven inches away from the median line. In this case the tendon, the fascia, and the ligament were divided exactly seven weeks ago on Friday last; and she left London to return home last week with a straight and useful limb; such as she had never known before. I doubt if Mr. Parker has ever seen a worse case of genu valgum.

No. 3 was taken from a child, five years of age, in whom the inner malleolus was five inches removed from the middle line. This child was not operated on, but a splint was applied. This splint has been worn about a fortnight; and when I saw the child four days since the limb was straight, and it remained nearly straight when taken out of the splint. No force has been used, nor has there been pain. In which of these cases would Mr. Parker consider the treatment "inapplicable?" The former was sent up for osteotomy; and in the second it was suggested. Would either of these cases have been better for osteotomy? I regret that Mr. Parker cannot now see the first mentioned case. I shall be glad to show him the second if he wishes.

No. 2 was taken from a girl, nine years of age, on whom osteotomy had been performed some few months previously. The malleoli are nine inches apart.

Secondly, Mr. Parker seems to think that genu valgum depends on the length of the inner condyle, and that flat-foot follows knock-knee. On neither of these questions can I agree with him. Certainly genu valgum does not depend on the length of the inner condyle, and flat-foot does not, as a rule, follow knock-knee. The inner condyle may be four-tenths of an inch longer than the outer without occasioning knock-knee; and in the young child it is a matter of every-day experience that being flat-footed it gradually becomes knock-kneed.

Thirdly, I was unaware "that the greatest incentive to osteotomy has been the utter insufficiency of the older method." I confess myself unable to believe it, but, if it is true, doubtless more knowledge on the subject of treatment is needed.

It was said at the meeting on Tuesday by one whose surgical knowledge is beyond question, that the frequent application of osteotomy to genu valgum, as is now the fashion, is shameful. My own impression also is that osteotomy, as applied to the treatment of genu valgum, has been shamefully abused, and that it has become somewhat of a disgrace to British surgery.

I am, Sir, your obedient servant,

Grosvenor-street W., Nov. 22nd, 1880.

B. E. BRODHURST.

To the Editor of THE LANCET.

SIR,—In a recent paper on the Treatment of Genu Valgum, read at the Royal Medical and Chirurgical Society, Mr. Brodhurst laid great stress upon the dangers of osteotomy as one of the reasons for discountenancing its employment for the relief of this deformity. Almost in the same lines he stated that the operation was becoming too common; that numbers of surgeons were performing it wholesale, and with some fatal cases; and that he understood that one gentleman had even done it over three hundred times. In the subsequent debate I ventured to express the hope that, in

the interests of scientific accuracy, Mr. Brodhurst would tell us something more as to the experience of the gentleman he referred to; whether out of his 300 cases any bad or fatal results had followed. This request of mine appears to have escaped the memory of Mr. Brodhurst during his reply; and as I am not sanguine as to his answering it in any way hereafter, I will ask you to allow me to answer it myself, circumstances now enabling me to do so.

This morning I received through Dr. Macewen's kindness a presentation of a copy of his book on Osteotomy, just published. Turning to the question of the "mortality" of the operation, I find that he himself has performed it on 330 patients, or 557 limbs, to the extent of 835 osteotomies. Of these 330 patients one died of pneumonia (contracted before operation), one of tubercular meningitis, and one of diphtheria; in one (owing to an accident independent of the operation) amputation had to be performed. In other words, not a single case died of the operation! What other surgical procedure can show such results?—even those we are accustomed to call the "minor operations." For my own part, though no advocate of indiscriminate osteotomy, I will in the face of such facts, and of others collected during an extensive reading of the subject, refuse to regard osteotomy as a dangerous undertaking, even when assured that it is by so distinguished a surgeon as Mr. Brodhurst. If anyone is to be listened to on a question of the kind, surely it should be the surgeon who, having performed hundreds of such operations, lays the results of 835 of them candidly, honestly, and fearlessly before the profession. "These are hard facts, and worth more than all the vague expressions of distrust that have been uttered in any quarter up to the present."

Dr. Macewen's work also answers Mr. Savory's remarks in the same debate, that it was a "shame" and a "disgrace" that no osteotomist had up to the present published his results as to the ultimate benefit to the patient of the operation for genu valgum, as regards progression, &c. There were those present who ventured to think these remarks somewhat premature, and that probably it would be better to wait for observations on this point for some years after operation, than to draw deductions from a patient's powers only a few months after. However, Dr. Macewen answers these remarks, as also, strangely enough, those of his reviewer in your impression received to-night (*vide THE LANCET*, Nov. 20th, p. 817), who says that "the only results given in the book" are "from the point of view of recovery from the operation." His answer is, that afterwards "nine of them had walked from thirteen to sixteen miles at a stretch, six from seven to twelve, and three from three to six miles," &c.; and that "besides their personal appearance having been greatly enhanced, they had been enabled in many instances since their operation to engage in occupations from which their deformity previously excluded them." But this whole chapter is most interesting; what tenotomist could say more?

When we add to these osteotomies on 367 limbs, another 100 practised with "uniformly good result as far as ascertained" by other Scotch surgeons, of which Dr. Macewen speaks, and the other hundreds performed in England and abroad; and when we remember that, though attention has been called to the subject over and over again, those who have given time to the matter have only been able to tabulate some four or five recorded deaths (though I know of two unrecorded) as due to the operation, surely no one need ask us to believe that osteotomy is an essentially dangerous procedure. Apologising for my long letter,

I am, Sir, yours, &c.,

Harley-street, W., Nov. 19th, 1880.

ARTHUR E. BARKER.

THE INFECTION OF PHTHISIS AND ITS BEARINGS UPON TREATMENT.

To the Editor of THE LANCET.

SIR,—In commenting on the important article on Infection in Phthisis, by Dr. Reginald E. Thompson, Dr. Robert Lee remarks on the indications which the germ theory affords for the treatment of tubercular disease, and concludes by stating that "the question of atmospheric conditions takes precedence of others, when considering the subject of the treatment of phthisis pulmonalis." I agree with him in this expression of opinion, and, having for some time been engaged

in the study of the subject, venture to lay before your readers some observations thereon.

That a resemblance exists between the tubercular process and septic poisoning seems to be beyond doubt. This is seen in the clinical study of the thermometry of the two classes of disease. Various authors have recently directed attention to this fact, notably Professor Charcot of Paris and Dr. Waters of Liverpool. In his most recent contribution to the literature of the subject, the former remarks, "the thermic curves are not those of inflammatory action, but of putrid infection," and he goes on to show that "in the pyrexial form of phthisis, the evening exacerbation (of temperature) is due not to a pneumonic process, but to resorption of the softened material." Common phthisis is regarded by Dr. Clifford Allbutt as "cases of pure ulcer, these ulcers constantly being the seats of foul secretions of some kind or other, and producing chronic pyæmia." He also remarks on the peculiar susceptibility in some persons to septic influences in the lung.

Recent research seems to show that this septic poison is eminently contagious. As the result of experimental inquiries, Klebs believes that tuberculosis is an infectious disease of parasitic origin, induced by certain micro-organisms which invade the body and multiply in it, and that the expectation might be entertained of curing it by the employment of means which are calculated to annihilate these organisms. Schüller of Griefswald has proved that animals in which artificial tuberculosis has been induced by injection die, without exception, with the usual phthisical symptoms—viz., emaciation, loss of heat, and afterwards general miliary tuberculosis. Amongst others who have given the weight of their authority to the belief that tuberculosis is contagious are Mr. Simon and Dr. Greenfield; such contagion being frequently spread by the milk of high-class cows, which are very subject to the disease.

The interesting paper by Dr. Thompson, previously referred to, seems to show beyond doubt that pulmonary consumption may be propagated by direct infection from man to man. Dr. Murrell had previously directed attention to this fact, and in THE LANCET of May 22nd of the current year he records a clear case where a wife was infected by her husband. It is important to note that whilst the lower animals may communicate the contagion to man, man may in return infect the lower animals. In proof of this is the case recorded by Dr. Cullimore (*British Medical Journal*, May 22nd, 1880), where a strong, healthy dog, lapped up the sputum of a tuberculous man, and died in a short time of pulmonary phthisis.

With these considerations in view, the practical part of the question—namely, treatment—may be approached. Now the point arises whether all phthisical patients should be treated on the same broad basis, or whether there are varieties of the disease sufficiently distinct to render a method of treatment which might suit one form unavailing or prejudicial in another. The unity of the virus in the different pathological conditions grouped under the name of phthisis appears to have been fairly ascertained by the recent experimental researches of Cohnheim, who claims to have established that the poison of true tuberculosis is identical, not only with that met with in the other forms of phthisis, but also with that present in scrofulous glands. This, however, is scarcely borne out by the state of affairs at Quito, where, according to Domee, phthisis is rare, and yet various forms of scrofulous disease are so common as to impress a peculiar character on our surgery. But be this as it may, it seems to be generally accepted, both as a result of clinical observation and experimental pathology, that in phthisis pulmonalis we have to deal with a disease of a septic parasitic origin, presenting a variety of pathological features, and under certain conditions readily infectious. We have here a clear indication for the employment of antiseptics.

The beneficial results following the use of antiseptics in phthisis have been long noted. At the Social Science Congress held lately in this city, a discussion occurred on the cause of the increasing prevalence of consumption amongst the native Highlanders. The president of the section (Dr. Beddoe) was inclined to attribute it to the changes which had of late years taken place in the domestic arrangements of their homes, and notably to the substitution of modern fireplaces and fuel for the old peat fire in the centre of the apartment. Twenty years ago attention was

directed to this same subject by Dr. Morgan (now physician to the Manchester Royal Infirmary), and in a very interesting communication to the *British and Foreign Medico-Chirurgical Review* he shows that the smoke of peat, by virtue of the antiseptic substances it contained, had a marked beneficial action on the lungs of those breathing it. These and other facts enable us to answer the question, Should the employment of the antiseptic be local or constitutional? My therapeutical experience leads me to believe that, as shown by Matthews Duncan to be the case in some examples of puerperal fever, it is more frequently a condition of sapræmia than pyæmia which obtains in phthisis—that the toxæmia is rather attributable to the chemical factors which putrefaction engenders than to the presence of micrococci in the tissues and blood. I therefore think that it is only by the local application of the antiseptic that good results can be obtained.

In applying this principle to practice, I have for the last year and a half been in the habit of using what might be called a naso-oral antiseptic respirator—i.e., a respirator which covers both the mouth and nose, and contains a volatile antiseptic, which is drawn into the lungs with each inspiration. This respirator is provided with inspiratory and expiratory valves, is not liable to get out of order, and is easily worn. I have treated several cases of phthisis with it with considerable success, and now subjoin brief notes of two cases. I select these as having been seen by other medical men than myself, and the first also as showing that a child may respire an atmosphere of pure creasote not only with impunity but with positive benefit.

CASE 1.—A. G.—, female, aged seven, consulted me on Oct. 20th, 1879. She complained of cough, sputum occasionally tinged with blood, emaciation, and nocturnal sweats. Had been getting worse for months. On physical examination there was rough, jerky respiration, with prolonged expiration at the left apex anteriorly; pulse small and soft, 106 (a few days subsequently it was 140) per minute. As she seemed to become worse under the ordinary treatment, on Dec. 4th she commenced to wear an antiseptic respirator charged with pure creasote. On Dec. 15th the results noted are—(1) increased appetite, (2) quieter nights, (3) less cough and vomiting, (4) slight fall in the pulse-rate, (5) still hot and feverish in the evenings. On Jan. 5th (still continuing to wear the respirator) she had apparently quite recovered. On Jan. 12th she was shown at the clinique of Professor Grainger Stewart in the Royal Infirmary; she then seemed all right. On Jan. 17th she ceased to wear the respirator, and returned to school. On Oct. 4th I met the mother of the patient in the street, when she informed me that her daughter had continued well ever since.

CASE 2.—This case occurred in the practice of the late Dr. Forbes, of West Newington-terrace, in this city, and but for his untimely death would have been recorded by himself. From Dr. Forbes's letter, now before me, regarding the case, I find that the patient, a male, aged twenty-five, sent for him in January last, complaining of general debility, shortness of breath, and loss of weight. On physical examination the right pulmonary apex was found to be affected (consolidated). The ordinary routine treatment was tried for some time, but without the slightest benefit. In February, on the recommendation of Professor Grainger Stewart, who saw the case in consultation, the use of the naso-oral respirator was commenced, charged with equal quantities of pure creasote and carbolic acid. Rapid improvement soon ensued, and, instead of being confined to bed, the patient was shortly able to leave for the Channel Islands. On July 6th, through the courtesy of Dr. Forbes, I was allowed to interview this patient. He was a very intelligent young man, and stated that, before commencing the use of the respirator, he was so ill that at the consultation the doctors told him "there was not much hope." He still (November) continues well.

I have experienced equally good results in similar cases in my own practice; these I purpose submitting to the profession on a future occasion. I have already considerably exceeded my original limits, and shall conclude by expressing my opinion that in the correct application of antiseptics to the treatment of phthisis we are on the proper track towards the solution of a problem which has for long been an *opprobrium medicinarum*.

I may mention that the respirators, as used by me, are made by Mr. Gardner, South Bridge, Edinburgh.

I am, Sir, yours obediently,

G. HUNTER MACKENZIE, M.D.

Edinburgh.

THE CRISIS AT GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—A good deal of surprise has been expressed in many quarters at the fact of the staff of this hospital, notwithstanding the extraordinary treatment which they have received at the hands of the treasurer and the governors, still continue their connexion with the charity, and it is asked why the example set by Dr. Habershon and Mr. Cooper Forster has not been followed by all their late colleagues. Their hesitation to take this step we consider to be due chiefly to two motives, both of them extremely honourable to the members of the medical staff; but we fear there is danger of both of them being carried to excess, and so defeating the very ends they have in view. These motives are: First, a genuine regard for the welfare of the patients under their care; and, second, a fear of injuring the Medical School by hasty action.

There can, of course, be no doubt that if the physicians and surgeons were suddenly to resign in a body the result to the patients in the hospital would be disastrous in the extreme; for, even supposing that the treasurer was able to find qualified medical practitioners willing to take the vacant posts (which we think very improbable), they would certainly not be men of the eminence requisite for such an institution as Guy's Hospital, and it would be quite impossible to obtain substitutes of any kind at a day's notice. Moreover, the interests of the Medical School would suffer most severely from such a course of action, deprived as it would be of its lectures and of its practice in the wards; and much time must necessarily elapse before arrangements could be made for our attendance at other hospitals. We are, then, compelled to admit that anything like a sudden and universal resignation of the staff is out of the question; but it is, at the same time, equally clear that the present state of affairs cannot, in the interests of both patients and students, be allowed to continue. What, then, must be done? How are the difficulties embodied in the above objections to be surmounted? We, with great diffidence, would suggest a procedure somewhat as follows.

Although the medical staff would be wrong if they were suddenly to resign in a body, yet it seems to us that they would be perfectly justified in so doing, provided that they gave the governors due notice of their intention, say, a fortnight or three weeks. This interval would give the treasurer an opportunity for considering his position, and the governors of deliberating as to the course they should pursue. If they persisted in their present attitude, they would have time to make arrangements for the welfare of the patients, and to attempt the organisation of a fresh staff, though we hope the *esprit de corps* of the profession would prevent anyone from coming forward to take the vacated posts. If this were the case, the governors must either yield or close the hospital. If, on the contrary, it should be found possible to collect a new staff, we have already expressed our opinion that they would certainly not be men of the necessary ability and experience. We see then, that the governors would be reduced to three alternatives: either the existing obnoxious regulations must be repealed, or the hospital must be closed, or it must be worked by an inferior class of men. In either of the two latter cases—the appointment of incompetent men, or the cessation of a great medical charity such as Guy's—public opinion, already aroused, would demand a full inquiry into and a thorough sifting of the state of affairs which is at present a scandal to the whole medical profession, and this would undoubtedly result in the vindication of the authority of the medical over the nursing staff. Whether then the governors agree or refuse to yield, the final upshot must be the reinstatement of the original staff and the former *régime*. But the settlement of this point would necessarily occupy some time, during which the interests of the students might be detrimentally affected, and the interval we have mentioned should be employed by the Medical School in taking measures for securing its own safety in case the battle should be prolonged. Again and again we have been told that we have the wishes of all the London hospitals with us; now is the time to put this to the test, and we ask for their co-operation. We would suggest that a meeting should be convened of the authorities of all the London schools, and that they should discuss the possibility of making

some arrangement for the temporary distribution of the Guy's students among the other hospitals, should the necessity for such action arise. Before the three weeks' notice had expired everything should be ready for emigration; and not only must everything be ready, but the emigration must, if matters are allowed to go far enough, really take place in solemn earnest. Surely some agreement could be come to by which we poor persecuted medicals should find a temporary home in the other hospitals of London. The need for it could only be temporary, for however long the strife might be protracted, it cannot be doubted that when the final struggle did take place we should be victorious. Would it not then be wise to precipitate the crisis instead of allowing the reputation of both hospital and school to be ruined by needless delay? We cannot see that anyone would be seriously injured if such a course were adopted; certainly, if any harm came to the patients, the treasurer alone will be responsible for it; the staff would have done all, and more than all, their duty in giving the notice we advocate. The school could not be permanently injured; individuals, no doubt, would suffer some slight inconvenience through giving up appointments for a time, but we apprehend they would be content to do so *pro bono publico*. The very fact that the hospital cannot be satisfactorily worked without the assistance of the school would necessitate its speedy reinstallation.

The plan we have proposed may not be either new or original, and it may not be the best that can be imagined, but we think it to be at any rate worth consideration, and we therefore respectfully ask for a small space in your valuable paper. If it evokes criticism it will have served its purpose.

We are, Sir, your obedient servants,

Guy's Hospital, Nov. 23rd, 1880.

TWO STUDENTS.

RECORD OF A NIGHT WITH THE CHARGE OF A DELIRIUM TREMENS PATIENT.

To the Editor of THE LANCET.

SIR,—Perhaps you may deem the following particulars worthy a place in your columns.

A publican's widow, aged forty-five, had a first attack of delirium tremens in Nov. 1879 (three months after her husband, who had lived for years in the tropics, had died of the same disease). Her second attack happened in August, 1880, on the 24th of which month she had premonitory symptoms and was prescribed essence of beef and milk freely; also one drachm of tincture of opium, in divided doses, with a little quinine and sulphuric ether. Bowels freely open. On the night of the 26th she had two drachms of tincture of opium, in divided doses; and on the 27th, ten minims of solution of opium, every three hours, with quinine and tincture of bark. By this evening she had been sleepless for three days and two nights. The usual delirium was now as high as possible, and she was engaged incessantly gathering up the bedclothes. At 10.15 P.M. she unwillingly took half a drachm of chloral, in seven or eight minutes after which she vomited some curdled milk and watery fluid. A mustard cloth was then put over the region of the stomach, and ten minutes afterwards another half drachm of chloral was given in an ounce of sugar water, with ten drops of ginger-brandy, her favourite cordial, to flavour the dose. At 11 o'clock fifteen grains more in a similar manner. At 11.30 P.M. another fifteen grains, making one drachm or more retained altogether. After this the patient was more quiet, but still excited. The excitement increasing, I injected into the arm nearly one-third of a grain of morphia. Ten minutes after this she stretched out her arms saying, she "felt stiff in the head and sinking;" face drawn, rigid, and having an intensely anxious look (the heart had been intermitting after every second beat; pulse very weak at wrist; heart's beat easily becoming very rapid with the movements of the patient). I then had her head drawn over the bedside, with a foot-bath on the floor beneath, and poured about half a ewerful of water over the forehead. While doing this she once or twice said, "That will do." Presently she uttered a sharp sudden cry, and gave two or three spasmodic movements of the body; the head rotated to the right, and at the same moment I thought she dropped with lightning speed into a catastrophe of sleep, which after a moment seemed to end in the flaccidity of death, one or two gasps preceding this apparent end. Three

women in the room, the sister, a servant, and a nurse, gave a cry and rushed to the door, uttering words relating to the dead or death. The sister came back, and, with clenched hands and body bent over the foot of the bed, besought my opinion. The men came upstairs. For a few seconds I halted between the words "sleep" and "death." I felt no movement of the heart, no pulse at the wrist. The body was motionless, the head resting on my arm. After a few moments of breathless suspense, listening over the præcordia, I heard the flickering heart. Then the wrist-pulse came. I then restored the patient to her old position in bed, and in a few seconds the excited movements recommenced. But in a few more moments she fell suddenly into a quiet, deep slumber, and the wrist pulse became regular, fairly full, and about 70. After watching two or three minutes I left her, and went downstairs to take some bread-and-butter and cocoa. After she had slept for about fifteen minutes I was fetched to her. She had awoke, and was vomiting. Her restlessness and excitement became as bad as before. I had a mustard plaster put over the epigastrium, and in about a quarter of an hour administered fifteen grains of chloral, as before, and in about half an hour after another fifteen grains. Feeling the extreme importance of securing sleep of some duration promptly, I resorted to the water once more, and poured the contents of the full water-ewer three or four times over the forehead, allowing it to flow down her streaming hair into the bath. This time the treatment was most acceptable to the patient, and in the midst of her mutterings about water-pumps, rain, and water-rates, said, "Hold the jug higher, doctor." She was moved into her old position, and I left her quieter, but muttering and talking while she gathered up the bedclothes. I went myself to bed in a room over hers, and lay listening to the humdrum of her talk as it came through the floor. At 5.15 A.M. I went down, and finding she had not slept, gave her thirty grains more chloral, as before, and another jug or two of water fifteen minutes afterwards; after a further fifteen minutes, thirty grains more of chloral. Feeling I should wait awhile before doing more, I went upstairs again to bed, directing that I was to be called if anything happened to give additional uneasiness. She was much quieter, for I could hear now no sounds of her voice. At 6.45 there was a tap at the door to tell me she looked very strange, turning her eyes up; and in another minute, as I was preparing to go down, a message came that she had fallen asleep. I was content, and tried to sleep myself. At 9.30 I looked into the room. She was still asleep. I advanced quietly to the bedside, and moved my hand over the eyes to disturb three or four flies walking over the eyelids, when she at once opened her eyes, and, in answer to my question, told me she was awake by my walking across the room. I directed her to have a cup of tea and a piece of bread-and-butter, which she drank and ate. She slept, on and off, through the day, and was well again.

The catastrophe in the night reminded me of a startling event late one Saturday evening last winter. I was driving home along a country road and had to turn a sharp corner when I came upon a public house which was closing. I suddenly saw in the middle of the road a man and a woman talking. I halloed and drew in my horse, but with the result of just tapping the woman with the end of the shaft a spent blow, the result being that she fell flat on the road like a skittle. I sprang out of the trap and, on bending over her, received a volley of abuse from the tipsy man, and at the same time heard the woman *snoring asleep*—sleep, the work of a moment, and following instantly the shock of her fall produced by only a touch.

I am, Sir, yours truly,

Kenley, Caterham Valley.

E. DIVER, M.D.

PARIS.

(From our own Correspondent.)

A FACT of great importance, and which had been discovered accidentally, was related by Dr. Brown-Séquard at a recent meeting of the Société de Biologie. Intending to kill a guinea-pig, the subject of previous experiment, the animal was placed under a glass globe with a certain quantity of ether. Anæsthesia progressing but slowly, some

chloroform was poured on a sponge, which was inserted in the summit of the globe in such a position that some drops fell between the guinea-pig's neck and shoulder—that is to say, upon the epileptogenic region, when an attack of epilepsy immediately took place. The experiment which had thus been accidentally suggested was repeated a large number of times, and it was found that no longer epilepsy, but a deep anæsthesia, followed the application of chloroform. The same thing was afterwards observed in cats, dogs, and rabbits. As the anæsthesia passes off, the animal gives evidence of returning nervous and muscular sensibility; there are tremors in the four limbs. Then it tries to get up, but presents either hemiplegic or paraplegic symptoms, such as were noticed before anæsthesia took place; occasionally there is delirium, and when consciousness has returned there is a considerable degree of hyperæsthesia, and may be inflammation of the skin if the dose of chloroform has been strong. When the experiment ends fatally, death may occur either suddenly or less quickly.

In this case a series of symptoms—such as convulsions, epileptiform attacks, diminution of reflex action on the side of the application, in the cat myosis, and mydriasis in the dog—precede the slowing of the respiration, which sometimes appears to be superior thoracic, the diaphragm being paralysed, or contracting only on one side. Finally, the temperature falls, and the animal dies suddenly, and without convulsions, from syncope. Electric exploration shows that nervous excitability is strangely modified. A weak galvanic current calls forth a response, and this excitability often lasts four times longer than after other modes of death. In two dogs, and in several guinea-pigs, the phrenic nerve on one side was found to have entirely lost its excitability, and the corresponding half of the diaphragm was less irritable than the other—this on the opposite side to the application of chloroform. Dr. Brown-Séquard explains these phenomena by the theory of inhibition, arrest of function by distant nerve action, and particularly by that inhibition which he has described as the *arrêt des échanges*. The experiments carried on at the Collège de France will give an additional interest to the lectures which commence, as usual, about this time.

INDIA.

(From an occasional Correspondent.)

SOME months since, in a previous letter, I noticed a letter in the *Pioneer*, by "Scrutator," tracing the frequent epidemics of cholera among the Assam coolies to the faulty bathing arrangements and water-supply on board the steamers. Fortunately, the letter attracted the attention of the Lieutenant-Governor, who ordered certain suggested improvements to be adopted. "Scrutator," in a second letter, June 3rd, 1880, now writes: "The water-supply on board the steamers is now nearly perfect. Water is pumped up fresh out of the river into a long closed receptacle, from which the coolies draw it in any quantity they like through strong substantial taps . . . The water-supply of the Calcutta depôts is so radically bad that it will be impossible to make it altogether satisfactory until the principal water-pipes are extended to Sealdah, where the depôts are situated. Still great improvements have been made; the tanks have been fenced off so as to be quite inaccessible to the coolies." A sufficient time has now elapsed to admit of a tolerably correct opinion being formed of the effect of these improvements, which, however, it must still be remembered, are incomplete. Since May 1st, 1879, when the new arrangements on board the steamers got into fair working order, 5124 coolies were carried from Goalundo with 39 deaths, and 4534 from Dhubri, with 17 deaths from all causes. These figures give a percentage mortality for the Goalundo coolies of 0.76, and for the Dhubri coolies of 0.37. The corresponding percentages in 1878 and 1879 for the two classes respectively were 2.70 and 3.78 for Goalundo, and 1.72 and 2.43 for Dhubri coolies. The mean of the previous five years for Goalundo was 2.5, and that of the four years of the existence of the Dhubri depôts 1.56 per cent. It must here be noted that the remarkable reduction shown by these figures was effected in a year of ex-

traordinary cholera mortality in the district bordering on the Brahmaputra. But now the question arises, "What caused the reduction?" I would say that as the conditions of last year were identical in all respects with those of previous years, except in the matter of water-supply, the changes in the water-supply caused the decrease in the mortality from cholera. The testimony of two medical officers who have had many years' experience of coolie emigration is very decidedly to the same effect. Dr. E. G. Russell, the Civil Surgeon, Gauhati, writes: "Since these minute and detailed arrangements for ensuring an untainted supply of water have been introduced, and *de facto* carried out in their entirety, bowel disorders have almost disappeared as a cause of mortality among imported coolies. When it is remembered that previous to the introduction of these water arrangements the short trip of a few days (from twelve to eighteen, according to the port of disembarkation) was, in many instances, attended with decimation or, in certain instances, worse, the remarkable recent diminution, or one may almost say suppression, of the mortality is a very startling fact." Dr. Slane, the Civil Surgeon of Dhubri, writes: "I do not think there can be any doubt to what the freedom from cholera on the steamers is attributable. The only thing in which a radical change has been effected is the water-supply, and by a similar gradation the disease has abated and almost disappeared. In presence of the facts furnished by the great experiment which has been going on for nearly twenty years on the Brahmaputra steamers, I think there can no longer be a doubt that water is the main channel by which cholera is spread. Having studied the water-supply arrangements in many stations and in various parts of the country, my deliberate opinion is, that ninety-nine out of every hundred cases of cholera are due to bad water, and about the same proportion of the deaths caused by the allied disease (typhoid fever) are due to the same cause. There is a great variety in the defects of the water-supply of different stations; but there are very few stations indeed in which the supply is not extremely bad. The *bhisti*,¹ the *guala*,² and the *dhohi*³ are the main channels by which Europeans in India become infected with cholera and typhoid fever."

Obituary.

MR. HENRY BATEMAN, F.R.C.S. ENG.

ON Sunday last Mr. Bateman, of Islington, one of the best-known and most marked practitioners in London, died at the goodly age of seventy-four years. Mr. Bateman's history, as that of one of the most prominent of the older class of practitioners, is of interest. He was born on September 30th, 1806, at Burton-upon-Trent, and educated at the Burton Grammar School. At the age of fourteen years he was apprenticed to Mr. Septimus Allen of Burton for five years. In October, 1825, he came to London, and began the study of medicine at St. Bartholomew's Hospital, an institution for which he always retained a great respect. Amongst his fellow students was Professor Owen, with whom he shared his first dissections. He attended the lectures of Mr. Abernethy. The office of Librarian, an appointment then given to deserving students, was given to Mr. Bateman. From September, 1826, to September, 1828, he acted as assistant to Mr. Jones of Henley-in-Arden. In October of the year 1828 he became a Licentiate of the Society of Apothecaries, and in January, 1829, a member of the Royal College of Surgeons, of which, in 1855, he was made a Fellow. Through 1829 he continued his hospital studies, and specially attended the Eye Infirmary, Moorfields, for three months. In this year he also entered the *Ecole de Médecine*, Paris, and attended at the *Hôtel Dieu* the lectures of the celebrated Dupuytren. In January, 1830, he was made surgeon to the Islington Dispensary, and commenced practice on his own account in the same year. He was fond of reverting to the humble beginnings of his large practice, and the modest but ever-increasing annual receipts. In 1832, during the epidemic of Asiatic cholera, he was appointed surgeon to the Cholera Hospital, River-lane, Islington, and, after wisely making

his will, made post-mortem examinations of every case that died under his care. He remained surgeon to the Islington Dispensary more than three years, and became senior surgeon to the same at twenty-four years of age. He resigned the appointment when he married, and was made consulting surgeon. He then began his well-known practice of seeing patients gratuitously. For eight years he saw them so daily, and subsequently, down to a few years ago, three times weekly, beginning at the early hour of six, and in summer mornings before this, and closing the door of the room for this purpose at the foot of his garden with severe punctuality at nine. It was common for him to see on those mornings from 50 to 100 people, who preserved his prescriptions with a reverence that testified to their utility.

The above mere history implies a good deal of character, thoroughness of study, love of work, and early rising. Before most men had got their breakfast Mr. Bateman had cleared off his gratuitous patients, and was hard at work in his private consulting room, which was seldom empty, till he went on his round of daily medical duties, from which nothing could divert him, unless something he could do for his beloved church. He was a most devoted believer in the doctrines of Swedenborg, and one of the mainstays of the New Church in the metropolis. Until a comparatively recent period he used to preach once every Sunday in the New Church, Devonshire-street, Islington, and as he had to get up at five o'clock on other mornings to see his gratuitous patients, he had often to get up little later, on Sunday mornings to write his sermon. He was a hard-working man, not because he was constitutionally stronger than others, but from a strong love of work and sense of duty, stimulated, perhaps, by a large family, who have deeply to feel his loss. Not the least lesson in Mr. Bateman's history is the fact that he was not constitutionally strong, and temperate almost to teetotalism. In his early practice, in three Augusts running, he had an attack of hæmoptysis, compelling him to the habit of a fortnightly summer holiday, which he took as religiously as Sir Henry Holland took his two months. In middle life his heart became weak, but by slight rest and a daily dose of tincture of acetate of iron at dinner, it regained power enough to enable him to complete fifty years of practice. Few men in general practice in London have been more called into consultation than Mr. Bateman was, no case coming amiss to him, whether surgical, medical, or obstetric. Such readiness to help brought practitioners and patients to him in all emergencies, from parts far remote from the immediate sphere of his own practice. Notwithstanding the strong love of work and sense of duty which dominated Mr. Bateman, he could not have done what he did but for two habits—one, early rising, to which we have already referred; the other the steady refusal to accept social engagements. He declined dining out, even with his own family, and the only exception which he admitted was to dine at the College dinner every second year.

Such briefly, but very imperfectly, is the history of Mr. Bateman's character and work. After fifty years of such work a man may be held to have served his generation well and to have set a splendid example to younger men. But when he disappears he does so conspicuously, and Islington practitioners will long continue to miss his characteristic figure, his bright face, his animated and intellectual conversation, and his hopeful and sanguine views of disease. In his last illness he was attended by his son, Mr. Alfred G. Bateman, and his friend, Dr. Glover, with the kind occasional advice and service of Mr. Gowland, Sir James Paget, and Mr. Christopher Heath. His illness was long and very trying, but his faith was equal to it, and he suffered, as he had laboured, "in cheerful godliness."

DR. ALFRED HUDSON.

It is with great regret that we have to announce the death of Dr. Alfred Hudson, Senior Physician in Ireland to the Queen. Dr. Hudson was born in 1808 at West Bromwich; he was the son of the Rev. John Hudson, a respected minister of the Congregational Church there for forty years. After studying in London for some time, he went to Trinity College in 1828, and became a most ardent pupil of the great Irish School of Physicians. Like his eminent Irish teachers, he studied fevers and wrote on them. He was also the author of an article on Typhoid Pneumonia. Like Graves, Stokes, and Corrigan in Ireland, and like Alison and

¹ Water-carrier. ² Milkman. ³ Washerman.

Christison in Scotland, he distinguished himself by the consideration of the great human and social bearings of the national epidemics of fever—a consideration which has its fruits now in the greatly diminished prevalence of typhus in both these divisions of the kingdom. Dr. Hudson was a good instance of a man attaining character and experience as a country practitioner, and then being called, as it were by general judgment, to a higher and metropolitan position, which he fully sustained by the courtesy of his manners and the accomplishment of his professional mind. When Dr. Stokes died, Dr. Hudson was appointed both to the Physicianship to the Queen and to the Crown appointment for Ireland in the General Medical Council. Here he took no active part. We do not remember his making one speech in the Council from the time of his appointment in 1877. His resignation took place a few days ago.

GUY'S HOSPITAL.

At a well-attended meeting of the Governors of Guy's Hospital, held on Thursday afternoon, the resignations of Dr. Habershon and Mr. Cooper Forster were accepted, and Dr. Hilton Fagge and Mr. Davies-Colley were elected respectively to the posts of physician and surgeon. The junior vacancies were not filled up.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 18th inst.:—

Appleford, Stephen Herbert, Champion-grove.
Baird, Andrew, Plymouth.
Campbell, Henry William, Claverton-street, S.W.
Chisholm, William, Goulburn, New South Wales.
Cockell, Edward Seaton, Hackney.
Cooper, Richard Gilpin, Southport.
Day, Thomas Montagu, Harlow, Essex.
Fielding, Edward, Rochdale.
Gabriel, Joshua Samuel, Ceylon.
Galpin, George Luck, Graham's Town, Cape of Good Hope.
Griffiths, Ernest Edward, Barnstable.
Lawrence, Joseph Henry, Frome.
McColloch, James, Swansea.
Otway, Alfred Carrol, Kennington-park-road.
Pasteur, William, Stratton-street, Piccadilly.
Pickthorn, Thomas Russel, L.S.A., South Kensington.
Pound, Francis Joseph, L.S.A., Odiham, Hants.
Renner, William, Quittah, Africa.
Stead, Geoffrey, Shrewsbury.
Thistle, Francis Thomas, Ashburton, Devon.
Watkins, Christopher James, Mornington-road.

Of the 82 candidates examined during last week, 52 passed to the satisfaction of the Court, and obtained their diplomas; 6 passed in Surgery, and when qualified in Medicine will be admitted Members; the remaining 24 failed to reach the required standard, and were referred for six months' further professional study. Four candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical degree or licence recognised by the College, were also admitted Members.

The following gentlemen passed the Primary Examination in Anatomy and Physiology for the Fellowship of the College at meetings of the Board of Examiners on Tuesday and Wednesday last:—

Messrs. Edward S. Bishop, Owens College, Manchester; John F. Bullar, Cambridge and St. Bartholomew's Hospital; Percy Warner, Guy's Hospital; Arthur R. Edwards, King's College; Ernest G. Colville, St. Bartholomew's Hospital; Charles Plant, Owens College, Manchester; Francis H. Weekes, St. Thomas's Hospital; James E. Square, St. Bartholomew's Hospital; J. Hutchinson Russell, London Hospital; and William E. Hoyle, Oxford and St. Bartholomew's Hospital.

Of the 22 candidates examined on the above-mentioned days, 12 failed to satisfy the Board, and were referred for six months' further anatomical and physiological study.

COLLEGE OF PHYSICIANS IN IRELAND.—During the November examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Frederick Wm. Exham, James Barry Gibbons, Clement Hadley, Joseph Patrick Kealy, Wm. Henry Christopher Macartney, William Watson Pike, John Ryan, Herbert Skipworth, Frederick Charles Stevenson, Samuel Malenoir Thompson, Richard Benson Warren.

MIDWIFERY.—James Barry Gibbons, Clement Hadley, Wm. Henry Macartney, William Watson Pike, Herbert Skipworth, Frederick Charles Stevenson, Richard Benson Warren.

The undermentioned Licentiates have been admitted Members:—

John David Hillis, Charles Benjamin Mosse, Arthur Herbert Orpen, Thomas Henry Pickering, Thomas Purcell.

DR. WILLIAM JONES has been re-elected Mayor of Ruthin for the ensuing year.

MR. ROBERT S. HAYES of Oberstown Hill, Naas, has been appointed to the Commission of the Peace for the County Kildare.

THE committee of the Chelmsford Dispensary and Infirmary contemplate the erection of new buildings for the charity. Towards the expenses of the enterprise £1375 has been raised.

At a late meeting of the Stepney Board of Guardians it was resolved that instead of paying their vaccination officer £65 per annum as heretofore, a payment of 1s. for each certificate of successful vaccination should be made.

DR. BURGESS, of Frampton, has been presented by the inhabitants of the town with a purse of fifty guineas, and an address expressive of their regret that the ill-health of the doctor renders necessary his departure from the neighbourhood.

A TESTIMONIAL, consisting of a handsome tea and coffee service and a purse of 105 guineas, has been presented to J. E. M. Williams, M.R.C.S. Eng., of Whitstable. The subscribers, numbering 500, desired in this way to express their appreciation of the worth of the recipient and the esteem in which he and his professional services are held by his fellow citizens.

ON Tuesday evening, Nov. 16th, the members of the Provident Dispensary attached to the works of Messrs. Tangye Brothers, Cornwall Works, Soho, Birmingham, presented their late medical officer, Cordley Bradford, L.R.C.P. Lond., with a beautifully illuminated address and a gold watch of the value of £25, as a token of the respect and esteem in which he is held by them.

THE guardians of the North Dublin Union have recently adopted a resolution to the effect that a dispensary should be erected on the workhouse grounds at a cost of £1200, and that a sum of £2000 be offered to the trustees of the Carmichael School of Medicine for their premises on the north side of the city as being admirably suited for the purposes of an additional dispensary.

THE CASE OF DISTIN.—On the 21st the Mayor of Bristol received a letter from the Home Secretary stating that he had caused a medical inquiry to be made into the former history and present condition of William Joseph Distin. He could find in the report which was made no grounds on which he could advise the Crown to interfere with the execution of the sentence of the law, which has accordingly been carried out.

THE BROWN INSTITUTION.—The annual course of five lectures in connexion with the Brown Institution will be delivered by Dr. W. S. Greenfield, Professor-Superintendent, in the theatre of the University of London, on Dec. 13th, 15th, 17th, 20th, and 22nd, at 5.30 P.M. Subject: "Further Investigations on Anthrax and Allied Diseases in Man and Animals." Microscopic specimens will be exhibited on Dec. 22nd from 4.30 P.M.

BIOLOGICAL ASSOCIATION, TRINITY COLL., DUBLIN. The following officers have been elected for the ensuing session:—President: Thomas E. Little. Vice-Presidents: Samuel Haughton, E. Percival Wright, Edw. H. Bennett, Edw. B. Sinclair, Knt., Henry Macintosh, John M. Purser, B. W. Richardson, James Little, Walter G. Smith, G. Pim, Alexander Macalister, John Barton, Charles B. Ball, G. P. Nugent, W. M'D. Wright.

THE Clerk of the Peace for Lancashire has received from the Privy Council the report of the Special Commissioner sent down to inquire into the cattle plague. It states that many outbreaks are owing to want of early information of the existence of the disease, and of early isolation in cases of suspected and infected animals. Periodical examination of cattle on infected premises, and the isolation of suspected animals, are recommended.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—At the annual meeting of the Aberdeen Medico-Chirurgical Society held on the 18th inst., the following office-bearers were elected for the year:—President, Dr. James Marshall; secretary and treasurer, Dr. James Rodger; librarian, William Fraser, Esq., surgeon; Council: Drs. Beveridge, R. Jamieson, H. Jackson, Charles Crombie, and William Fraser; representatives to the North of Scotland Medical Association, the president and secretary (*ex-officio*), Dr. R. J. Garden, and Dr. J. C. O. Will (elected).

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. James Seaton, of Manchester, bequeathed £1000 to Owens College. Mr. William Meyerstein, late of Love-lane, Aldermanbury, bequeathed £100 to the German Hospital, Dalston. Mr. John Gould, late of Didsbury, bequeathed to the Manchester Royal Infirmary, Barnes' Convalescent Hospital, and St. Mary's Lying-in Institution, £500 each; to the Salford and Pendleton Royal Hospital and Dispensary, and the Manchester Royal Eye Hospital, £200 each; to the Manchester Institution for Diseases of the Ear and the Stockport Infirmary, £100 each. Mrs. Bushell has left £50 to the Society for Providing Nurses for the Sick Poor, Belfast. Lord Ashtown has bequeathed £100 to the Hospital for Incurables, Dublin.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for the successful vaccination in their respective districts:—Dr. C. E. Ellis, Attleborough, £12 7s. (fourth time). Mr. T. H. B. Rodwell, No. 2 district, Loddon and Clavering Union, £7 4s. (third time). Dr. Hurley, Louth Union, £7 2s. (second time). Mr. Burroughs, Frome Union, £4 15s. 6d. Mr. J. A. Bright, Glastonbury (fourth time). Mr. A. J. Mackintosh, Downham Union, Norfolk, £12 3s. (seventh time). Mr. G. Pound, Odiham district of the Hartley Wintney Union (sixth time). Mr. G. K. Sproul, Rook-lane House, Frome (third time). Dr. J. S. Walker, Bucknall district of Stoke-upon-Trent, has also received a grant for the efficiency of the vaccination in his district.

SEAMEN'S HOSPITAL, GREENWICH.—The following shipowners have substantially testified their determination to encourage the Seamen's Provident Fund of the Dreadnought Hospital, at Greenwich, by giving donations of £100 each, in addition to their usual annual subscriptions:—Messrs. Donald Currie and Co., Carlyle Brothers and Co. (Ducal Line), Henderson Brothers (Anchor Line), Alfred Holt (Ocean Steamship Company), George Smith and Sons (City Line), and Thomas Wilson and Sons. The Committee of the Seamen's Hospital are in need of additional funds to enable them to meet the expenditure of the current year.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BARNEY, R. W., L.K.Q.C.P.I., L.M., L.R.C.S.Ed., has been appointed House-Surgeon and Dispenser to the Tiverton Infirmary, Devon.

BENNETT, STORER, L.R.C.P.L., M.R.C.S.E., L.D.S.E., has been appointed Assistant Dental Surgeon to the Dental Hospital of London.

BRAY, F. T., L.K.Q.C.P.I., has been appointed Medical Officer and Medical Officer of Health to the Rathangan Dispensary District, vice Watson, resigned.

BRIGHT, J. A., M.R.C.S.E., L.S.A.L., has been appointed Examiner of Army and Militia Recruits for Glastonbury and its neighbourhood.

COLLINS, Mr. J. H., has been appointed Public Analyst for Falmouth. Remuneration by fees.

COTTER, J., M.D., has been appointed House-Surgeon and Apothecary to the Cork North Infirmary, vice Corby, resigned.

DENHAM, J. S., M.D., L.F.P.S.G., M.R.C.S.E., has been appointed Medical Officer to the Westco District of the South Shields Union.

DUKE, A., M.K.Q.C.P.I., L.R.C.S.I., has been appointed Gynaecologist to Stevens' Hospital, Dublin.

EDMUNDS, W., M.D., F.R.C.S.E., has been appointed Resident Medical Officer to the Paying Patients' Department of St. Thomas's Hospital. £400 per annum, with residence.

FOX, T. C., M.B., M.R.C.S.E., has been appointed a Physician to the Victoria Hospital for Sick Children, vice Irvine, deceased.

FRAZER, D. M., M.B., has been appointed Assistant Medical Officer to the Metropolitan Fever Hospital.

GULLIVER, G., M.D., has been appointed Resident Medical Officer to St. Thomas's Hospital, vice Sharkey, resigned.

HAMMOND, G., L.D.S.R.C.S., has been appointed Dental Surgeon to the Western General Dispensary, Birmingham.

McDERMOTT, P., L.R.C.S.I., has been appointed House-Surgeon to St. Michael's Hospital, Kingstown.

MACGREGOR, D., M.D., has been appointed Medical Officer to the Denby District of the Penistone Union.

MARTIN, J. M. H., M.D., M.R.C.S.E., has been appointed Medical Officer to the Third District of the Fulham Union.

O'MEARA, J. B. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer of Health to the Sutton Bridge Urban Sanitary Authority. 10s. 6d. per case.

POPPLEWELL, T. W., M.R.C.S.E., has been appointed Medical Officer to the Wadhurst District of the Ticehurst Union, vice Harland.

REDWOOD, T., Ph.D., has been reappointed Public Analyst for one year for that part of Middlesex beyond the limits of the Metropolis.

SMYTH, A. C. B., L.R.C.P.Ed., has been appointed House-Surgeon to the Brighton and Hove Lying-in Institution, vice Blaker, resigned.

SPENCE, J. B., M.D., Assistant Medical Officer, Earlswood Asylum, has been appointed Medical Superintendent of the Staffordshire Asylum at Burntwood, near Lichfield, vice R. A. Davis, M.D., resigned.

STRICKLAND, A. W., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Kids Grove District of the Wolstanton and Burslem Union.

WATT, G., M.D., C.M., has been appointed Medical Officer to the Aberdeen Dispensary, vice Garden, resigned.

WATTS, T. F., M.B., C.M., has been appointed Assistant-Surgeon to Her Majesty's Convict Prison at Dartmoor.

WHITTERTON, J., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer of Health to the North Bierley Urban Sanitary Authority. £70 per annum.

YOUNG, T. M., jun., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the South Shields District of the South Shields Union.

Births, Marriages, and Deaths.

BIRTHS.

BARROW.—On the 19th inst., at Herbert-terrace, Herbert-road, Shooter's-hill, the wife of H. J. Waller Barrow, Surgeon, Army Medical Department, of a daughter.

HOOD.—On the 21st inst., at Green-street, Park-lane, the wife of D. W. Charles Hood, M.D., of a daughter.

LAWTON.—On the 22nd inst., at Poole, the wife of Herbert A. Lawton, L.R.C.P.L., of a son.

O'BRIEN.—On the 19th inst., at Cotehele-terrace, Stoke, Devonport, the wife of Henry J. O'Brien, Surgeon-Major, Army Medical Department, of a son.

WARD.—On the 22nd inst., the wife of J. Bywater Ward, M.D., Warneford Asylum, Oxford, of a son.

MARRIAGES.

CLARK—HALLAM.—On the 16th inst., at St. George's Church, Newcastle-under-Lyme, by the Rev. Richard Ward, B.A., Vicar, John George Clark, M.R.C.S.E., of 18, Colville-road, Notting-hill, W., to Fanny, second surviving daughter of the late John Hallam, J.P., of Newcastle-under-Lyme.

FINEGAN—KELLY.—On the 16th inst., at Curraha Roman Catholic Church, by the Rev. Joseph Wheeler, John S. F. Finegan, L.K.Q.C.P.I., L.R.C.S.I., of Addison Lodge, Glasnevin, to Ellen, daughter of James Kelly, Esq., of Creakenstown, co. Meath.

DEATHS.

BATEMAN.—On the 21st inst., at The Chestnuts, Canonbury-lane, London, after a long and painful illness, Henry Bateman, F.R.C.S.E., aged 74.

BRYDEN.—On the 18th inst., at Upper Norwood, James Lumsdaine Bryden, M.D., Surgeon-Major, H.I.M.S., aged 47.

HUDSON.—On the 19th inst., at his residence, Lowville, Merriem, County Dublin, Alfred Hudson, M.D., aged 72.

MURTAGH.—On the 17th inst., at Kingstown, Ireland, John Murtagh, Esq., M.D. (half-pay), 6th Foot, aged 82.

PHILPS.—On the 1st inst., at Piquetberg, Cape Colony, Vincent Philps, J.P. for Piquetberg, M.R.C.S.E., only son of Mrs. Emma Philps, of Sparrows Herne, Bushey, late of Berkhamsted, aged 28.

QUIN.—On the 24th inst., at his residence, Queen Anne's Mansion, Westminster, S.W., Frederick Hervey Foster Quin, M.D., in his 79th year.

SIMPSON.—On the 18th inst., at Thanet House, Basset, Southampton, Thomas Simpson, M.R.C.S.E., aged 75.

WILSON.—On the 19th inst., suddenly, at Middle-street, Brighton, from heart disease, William John Wilson, L.R.C.P., of Clay Cross, aged 46.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE BRADLEY MEMORIAL FUND.

At a meeting held on the 23rd instant, in the Old Town Hall, King-street, Manchester, Mr. EDWARD LUND, F.R.C.S., in the chair, it was resolved—"That this meeting of the friends who had reason to admire the character and public life of the late Mr. SAMUEL MESSENGER BRADLEY, F.R.C.S., desires in some suitable manner to perpetuate his memory; and, in order to secure this object, has decided to establish a Scholarship in Clinical Surgery in connexion with the Manchester Royal Infirmary."

The following gentlemen were appointed an Executive Committee to carry the above resolution into effect:—

CHARLES J. CULLINGWORTH, M.R.C.P.

FRANK GLOVER, Esq.

JOHN M. HETHERINGTON, Esq.

CAMPBELL HULTON, Esq.

DANIEL J. LEECH, M.D.

EDWARD LUND, F.R.C.S.

GEORGE H. MIDWOOD, Esq.

Hon. Secretary: WALTER WHITEHEAD, F.R.C.S.E.,

Notes, Short Comments, and Answers to Correspondents.

PROLONGED ENFORCED FASTING.

In the *Canada Lancet* for November, Mr. H. K. Kerr, of the Trinity Medical School, Toronto, narrates a case of esophageal stricture, which seems to afford a striking example of the length of time life may be prolonged without food. The stricture was induced by the patient swallowing, by mistake, a mouthful of weak lye. In the course of a fortnight symptoms of dysphagia began to appear, and, in spite of treatment, deglutition became more and more difficult until milk was the only nourishment that could reach the stomach. The patient became greatly emaciated, presenting the usual symptoms of starvation. In ten months his weight decreased from 120 lb. to 60 lb. During the remaining seven months previous to death he frequently attempted to partake of food, both solid and liquid, but could swallow no appreciable quantity of either, the only nourishment supplied to the system during this time being by means of enemata of milk-and-egg administered twice daily. The intellectual faculties and special senses seemed unimpaired. The power of locomotion was retained up to three days previous to his death, at which time his weight was not above 40 lb. Prostration set in, followed by dyspnoea, syncope, and death.

Dr. George Budd.—The paper will be inserted in an early number.

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—Kindly permit me to convey my thanks to Dr. Granville for his courteous reply to my query, which, however, he has left unanswered.

At different times I have made experiments with birds and animals with the view of determining this very question, and the result has been adverse to the opinion expressed by the Doctor, which was also at one time my own. I have been, on the contrary, compelled to admit that if there be a governing principle in the matter, it yet remains to be discovered.

With regard to a unity of placenta in the case of twins of different sex, I have met with four cases in my practice where such a phenomenon existed. On this latter point I would refer Dr. Granville to a discussion at a meeting of the Obstetrical Society, recorded in vol. xix. of their Transactions, p. 276.

I am, Sir, yours truly,

A. G. P.

M.D., M.R.C.P.E.—We recommend our correspondent to call on Mayer and Meltzer, Great Portland-street, who would demonstrate the use of the instrument to him in five minutes. He may also look into Cyon's little work, entitled "Electro-therapie," and Niaudet's "Traité Élémentaire de la Pile Electrique," 1878.

Mr. P. K. Cree, (Tahiti.) Thanks. The matter is scarcely worth notice.

PROPER COVERING FOR THE FEET.

At the Aberdeen Philosophical Society a few days ago Professor Struthers introduced a subject upon which, it would seem, the public, and especially the female part of it, require more than ever to be informed. The title of the paper read by the professor was "The Proper Form of Shoe considered in relation to the Anatomy of the Foot." After a short notice of the bones of the human foot and the characteristics adapting it to the erect position, and of the muscles by which the various movements of the toes are produced, Dr. Struthers said it was evident that the toes were meant to have freedom for individual action. The whole of the muscles of the great toe are separate from those of the other toes, except the slip from its long flexor muscle, which goes to the next two toes, and moves them at the same time, and the slip it receives from the short extensor of the toes; but the great toe has powerful separate muscles for moving up and down and sideways. The foot is capable of being trained to perform many actions usually performed by the hand. But irrespective of this capability, the toes are evidently naturally adapted for a freedom of motion which is denied them by the form of shoe usually worn. The distortion produced by the fashionable pointed shoes is the dislocation of the great toe, by which it is slanted towards the middle toe, the whole of the toes being pressed together to a point. This is apt to produce bunion over the inner prominence of the toe, and ingrowing toe nail, both very troublesome conditions. The inner edge of the shoe ought to be straight along nearly the front half of the foot. This implies what seems a very curved-in shoe, but it is the only form in which the great toe can be naturally lodged.

Dr. Cummings Air.—The paper is marked for insertion.

FISH-EATING AND LEPROSY.

To the Editor of THE LANCET.

SIR,—Mr. Hutchinson, in his letter on the above subject in your issue of the 6th instant, remarks "that he has not seen a single instance of leprosy in which the fish hypothesis was impossible; nor does he know of a single district where the facts, when sifted, are strongly opposed to it." The hypothesis will, I take it, be possible until it can be shown either that a leper has never eaten fish once in his lifetime, nor that any of his ancestors have done so, or that some other cause of leprosy has been definitely established as the true one. Neither of these conditions has as yet been fulfilled, and I, for one, cannot consider the fish theory impossible.

My object in addressing you is, however, to cite an instance (and I presume it would not be difficult to refer to others) of a district in which the facts are strongly opposed to the fish theory.

My friend, Dr. Arthur Reid, who is at present in this country, has brought with him copious notes of cases of leprosy observed at a native hospital at Hankow, China, over a period of fifteen years, special attention having been directed by him in his inquiries to the collection of evidence bearing on the etiology of the disease. Dr. Reid informs me "that the leper cases came from country districts within a radius of 100 miles from Hankow, being generally residents in hamlets composed of from five to twenty families. The leper applicant was often the solitary example of the disease in his family and township. The diet of these poor country people consisted of rice, millet, bean-curd, and a little oil, with pork two or three times a month, and fish at longer intervals. Many of the lepers stated that, owing to the extreme poverty of their families, they had only been able to procure pork once in two or three months, and fish only at the new year. In the large centres of Hankow and Wuchang, where river and lake fish can be purchased throughout the year, leprosy combined with a town ancestry of two generations is rare. I never met with a town case where either the patient or one of his parents had not migrated from a country leper district. Fish-eating is essentially in Central China the privilege of the well-to-do, while leprosy is usually found among the poor vegetable-feeders."

The observations of Hansen (Virchow's Archiv, vol. lxxix., 1880) on the *Bacillus lepræ* cannot fail to direct inquirers into a new field of study in reference to this disease. Through the kindness of Mr. Watson Cheyne I have had an opportunity of examining sections through lepra-nodules sent him by Dr. Koch. The presence in large numbers of the minute organisms described by Hansen, distinct when observed under favourable circumstances, but not so easy of observation as many of the forms of bacteria, whatever their precise relation to the primary cause of the disease may be, can hardly fail to have an important influence on its development.

I am, Sir, yours &c.,

Queen Anne-street, W., Nov. 8th, 1880.

G. THIN, M.D.

To the Editor of THE LANCET.

SIR.—As one who has studied attentively the etiology of leprosy, I beg to be allowed to give Mr. Hutchinson some references such as he asks for. The main argument, in short, for the causation of leprosy by a fish diet lies in the marked concurrence of the disease with the distribution of water on the earth's surface, and the use of putrid fish as an article of diet in islands, on sea-boards, and to a less extent inland. Virchow, indeed, looking to the illustration afforded by Norway, the shores of the Mediterranean, and many islands, thought leprosy "was limited to the borders of seas and large rivers." Hansen (as quoted by Carter), from a

more extended survey, which has not led him to adopt the fish theory, has expressed himself thus: "So far as I know, the sole condition which can with any tolerable certainty be regarded as universally prevalent in all these several localities (both at home and abroad)—i.e., where leprosy is known to prevail—is the vicinity of water, either salt or fresh." In the light of still more recent observations, which are well summarised by Dr. Munro (Leprosy, 1879), we must considerably modify even this statement; for leprosy is found in many inland and elevated districts and mountainous regions and far from rivers.

The College of Physicians' Report, p. 189, after stating that no castes are exempt, adds that the Brahmins and some of the higher castes of Hindoos in Mysore eat no kind of flesh, and though the lower castes do when they can get it, fish, fresh or salt, is very rare in Mysore (see also p. 185, Nagpore). At page 181 it states that "the majority of the people being Hindoos, they are strict vegetarians"; and again it repeats that leprosy is largely present amongst the vegetable-eating Hindoos, and (p. 134) it records that the inhabitants of the notorious leprosy district of Beerbhoom are exclusively vegetable-eaters (see also Macnamara on Leprosy, 1866, and Espinet's Reports from Trinidad, 1873-4). Vandeyke Carter, in his Reports of Leprosy, 1876, speaking of Western India, says that "many lepers have never tasted animal food," and, as regards the Crujerathi population, "by a majority of the people it may be said that animal food is scrupulously avoided." Again, in his Modern Indian Leprosy, 1876, Carter says of the diet in the Bhamagar district of Katiawar "animal food is very rarely used, only Mussulmans, a few Rajputs, and Kolis of lower grade will touch either flesh or fish." The same great authority on leprosy writes (Report on the Prevalence and Characters of Leprosy in the Bombay Presidency, 1872), at p. 14, that "there is no clear evidence that any special article of diet either excites or predisposes to leprosy," and "a very large proportion of the population of Western India are either solely vegetarians or partake only occasionally of animal food"; and again, at p. 37, "true leprosy has absolutely no apparent connexion with such diet"—i.e., fish; "and in Western India all castes, except most Brahmins, the Tains, and Lingaets, may partake of fish" (see also the interesting information collected in the list of castes). Turning to China, I would refer Mr. Hutchinson to the several articles in the Chinese *Customs Gazette* by Drs. Reid and Wong in support of the latter's statement that "it does not appear that fish-eating plays any part in the causation of the disease."

I am, Sir, yours faithfully,

Harley-street, Nov. 15th, 1880.

T. COLCOTT FOX.

"DENTAL-SURGEONS," "SURGEON-DENTISTS."

To the Editor of THE LANCET.

SIR,—Mr. Carpenter, in to-day's LANCET, calls upon me to give the details of the case alluded to in my last letter. It is the well-known case of Ladd v. Gould, with the particulars of which Mr. Carpenter is well acquainted. My statement of the issue raised in this case, and of its treatment by the Judge, is, I believe, substantially accurate.

Mr. Carpenter says: "The assertion that unqualified persons should have a 'right,' for the purpose of gain, to commit a fraud upon the public, by representing themselves to be qualified persons, is revolting nonsense to the common sense of the profession." With this I cordially agree; but I have never made such an assertion, and I deny that Mr. Carpenter's remarks fairly apply to the circumstances under discussion. Prior to the institution of a Dental diploma in 1858, there were a considerable number of well-instructed and accomplished dentists who possessed no diploma. They had received their professional education by pupillage with dentists, and had not obtained a surgical qualification such as at that time was held by some very few dentists. Most of these practitioners took the diploma in Dental Surgery shortly after it was instituted; but not being under compulsion, and not having the inclination, some did not present themselves for examination. There are still some totally "unqualified" dentists of this class, who are known both to the profession and the public as highly educated and skilful practitioners. At the time when these gentlemen received their professional education, and for generations before, it had been usual for such practitioners to style themselves surgeon-dentists, and they had established their right to do so by custom. Had the Legislature in framing the law, or the Judges in administering it, deprived all unqualified dentists whatever of the right to style themselves surgeon-dentist, an injury would have been inflicted upon a number of innocent individuals. No doubt somewhat on this account the penal clauses of the Medical Act of 1858 were interpreted as not interfering with unqualified practitioners acting *bona fide* as surgeon-dentists, and not fraudulently acting as medical practitioners, and hence the judgment in the case of Ladd v. Gould. A like judgment in a somewhat parallel, well-known case of an unqualified "surgeon"-chiroprapist may be cited as illustrating further the spirit influencing the Courts. It is somewhat astonishing to learn from Mr. Carpenter that "the Statute of Fraud" has any bearing upon these cases.

Your obedient servant,

Wimpole-street, Nov. 20th, 1880.

HENRY SEWILL.

Sanitarian.—"Portuguese" is a word suggested by Dr. Gibbs, Medical Inspector of the United States Navy, to express the infection-bearing quality of the "germs" of certain diseases.

Argus.—We do not gather from our correspondent's note that any steps have been taken to abate the nuisance from the works under section 114 of the Public Health Act, 1875.

Mr. T. H. A. Roskrugers.—We are glad to know the profession share our view of the Guy's Crisis.

NURSES FOR THE SICK POOR.

THE Northern Home, in Holloway-road, is an institution founded for the purpose of providing trained nurses for the sick poor. We have reason to know that much good work has been done by this institution, and that our brethren in the north of London have often realised the advantages of the home in affording a ready means of supply of attendants on the sick at once careful and skilled. A meeting was held this week to avert a threatened curtailment of the usefulness of the institution owing to the falling off in subscriptions. It would be matter of regret if a movement inaugurated to meet a recognised and urgent want should be allowed to collapse for lack of funds.

W. T. R.—Under the circumstances we cannot think there is any claim. The terms of the call seem to have been conditional.

Enquires.—The case is evidently one of severe gastralgia, and we should recommend the use of sedatives.

"INFECTED MILK: DIPHTHERIA."

To the Editor of THE LANCET.

SIR,—I hope you will excuse my offering a few remarks on your article—"Infected Milk: Diphtheria"—which appeared in THE LANCET of the 20th inst., page 827.

Every precaution was taken to isolate the patient, and prevent contamination of the milk. Not only was I not informed of the regulations made for the government of the dairies, but one of the largest dairymen in this district was also ignorant of them until this case was brought forward. Surely all medical men and dairymen should be officially informed of any rules that may be instituted with which they are bound to comply!

Holding a public office should be no excuse for a medical man intruding upon the patients of another. Such visits can seldom do otherwise than alarm, and may be very injurious. The dairyman's niece was in her fourteenth year, a delicate and very nervous, sensitive girl; and I was astonished to learn in court that the two doctors had "found her dying from malignant diphtheria." I have no hesitation in contradicting this; but the mother informed me that her daughter was greatly alarmed at the unexpected visit of the doctors and at their remarks, and no doubt she consequently presented a scared appearance. I had ordered her to be kept very quiet, which order was completely upset by this proceeding. The morning after the doctors' visit the diphtheritic membrane had completely cleared away, and it was not till the day subsequent that the girl died from suppression of urine.

I should be glad to know whether sanitary officers are justified in intruding upon the private patients of other practitioners and catechising them, as has been the practice at Surbiton, much to the annoyance of ladies and gentlemen. Also whether, in reporting to the sanitary authorities, with a view of publicity in the local papers, particulars of cases in which other medical men are concerned, they should not first satisfy themselves as to the correctness of such particulars from the medical men in attendance, and also from the other parties affected by their reports?

I am, Sir, your obedient servant,

Surbiton, S.W., Nov. 23rd, 1880.

R. COLLUM, M.D.

To the Editor of THE LANCET.

SIR,—I am the inspector and prosecutor in this case, and am solely responsible for the summary inspection as well as the cross-examination which you consider require explanation, Dr. Coleman being a witness only to testify that he had not received notice of the illness. Had the proceedings been more fully reported the explanation which I am now happy to give would not have been necessary.

On Monday, Nov. 1st, I received information from three sources of several cases of diphtheria arising presumably from one dairy, and I at once made an inspection in accordance with Section 50 of the Act.

On inquiry I was informed by the dairyman that a few weeks ago there had been illness in his house, and that there was a child ill at the time of my visit; that the former case was alleged by the medical attendant to have been croup, while the latter was stated to be an obstruction of the bowels. But having reasons for believing that there was infectious disease in the house, and seeing that the afternoon milk was about to be sent out, I considered that I could not delay my inspection without neglecting my duty and endangering the public safety.

Accordingly I requested Dr. Coleman to accompany me into the sick chamber. We found the child pulseless at the wrist, the lymphatic glands of the neck enormously enlarged, and the palate and fauces diphtheritic. Apart, however, from the urgency of the circumstances, I declined to meet the medical attendant.

I am, Sir, yours obediently,

Surbiton, Nov. 22nd, 1880.

WM. PRICE JONES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 20th, in your notice of a case that was heard at the Kingston County Board of Magistrates, under the Dairies and Cowshed Order, I am held up as having largely offended against the unwritten law of professional etiquette in my conduct in the above case as medical officer of health for the district. My only object in writing is to deny these charges brought against me, and to say that I regret they should have been made, for I am certain, Sir, that were you in full possession of the true facts of this, in many ways, painful case, you would not have allowed these statements to have appeared to the prejudice of Dr. Jones and myself.

I saw the child without previously communicating with Dr. Collum

because I noticed preparations for sending out that afternoon's supply of milk, which it was my duty to stop if the case were one of diphtheria, as I had every reason to suspect, and as it proved to be. As health officer, I had a duty to perform, and urgency was my reason for acting as I did; but I afterwards went direct to Dr. Collum's house to give an explanation, but finding him not at home, left my card, and wrote that same evening to him what I had done. I had nothing to do with "rigorously cross-examining" Dr. Collum, but, with the full permission of the Bench, asked him a couple of questions relative to a personal matter, which I need not here enter into.

I am, Sir, yours faithfully,

OWEN COLEMAN, M.D.,

Medical Officer of Health.

Surbiton, Nov. 23rd, 1880.]

Mr. H. Nuttall.—We do not see that there would be any great harm in a number of medical men agreeing to have their dispensing done at one place by a registered chemist; but we think differently of the proposal for them to form a Joint Stock Company for the sale of drugs and compounding the prescriptions of other medical men. This is to erect another, if a small, Apothecaries' Company, and to bring medical men into trade relations with drugs, which is exceedingly undesirable.

Mr. George Holt.—The subject is a large one. Our correspondent should study "Morbid Craving for Morphia," by Edward Levinstein, M.D., published by Smith, Elder, and Co.

"THE CHLOROFORM DEATH-BILL FOR TWELVE MONTHS."

To the Editor of THE LANCET.

SIR,—In my paper on this subject in your issue of Nov. 6th I distinctly guarded myself against making any charge on users of chloroform. No blame has ever been attached to a medical man by a coroner for using this substance, and there is no danger and need be no hesitation in publishing the case. But the difference between the accounts of the past ten years and those of a previous decade, shows how many cases may escape notice. My object in writing was to urge that there now exists an opportunity of forming a better opinion on the comparative merits of the two anaesthetics than ever was the case before, either having been in extensive use for the past five years. It is quite possible that all the deaths from ether have not been published. A few days ago a friend told me he believed he had lost a case from bronchitis after its use. With his permission I hope to publish the case in a forthcoming list of deaths from anaesthetics, but I have yet to learn that the "ether frenzy" has been followed by a "chloroform reaction." Ether remains the favourite anaesthetic at most of our large English surgical centres, both in London and in the provinces, its use is extending in private practice, is the most generally used agent with our professional anaesthetists, and the rising generation of medical men are being trained to give ether rather than chloroform. I repeat that the argument "I never saw a death from chloroform" is only worth anything if the experience has been exceptionally large, say of 5000 or 6000 cases. At the most, chloroform is fatal only once in 3000 cases. Still even this mortality is serious if by any means it can be reduced.

I am glad to hear ether is used in the Edinburgh Infirmary; but with regard to a mixture with chloroform, I may remind your readers that if the death which occurred in the ophthalmic practice at the Edinburgh Infirmary at the close of last year is to be ascribed to this, it makes the fourth death in the past four years from the mixed anaesthetics.

Lastly, may I say a word against the practice of giving ether from a sponge or towel. I cannot but think that, from the patient's point of view, this must be most unpleasant. Dr. Saundby recommends that the inhaler should be held down tight in case of struggling. With Clover's inhaler struggling hardly ever occurs.

I remain, Sir, yours &c.,

Leeds, Nov. 1880.

ERNEST H. JACOB, M.D.

Indicus.—Hart's Army List is in no respect an official publication, and may be fairly conducted in the way that seems best to the editor; but we feel sure that if our correspondent called the editor's attention to the omission, the information would immediately be supplied.

Dr. A. M. Anderson, (Dundee).—Thanks.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION AT BRISTOL.

To the Editor of THE LANCET.

SIR,—In reply to the letter of Dr. Ridge contained in your impression of Nov. 13th, I will, with your permission, say that I cannot see any connexion between drunken soldiers in the Madras army in 1847, and the sons of temperance in England in the present day. At the same time I must admit that my "imperfect knowledge" will not allow me to take in the statement that a total abstainer or any other man can live for a hundred and sixty years, more or less, without at least a lengthened explanation of the circumstances; and, in conclusion, I would assure Dr. Ridge that my sympathy goes with him heartily in the cause he has taken up, if he will only leave off statistics, and confine himself to the advocacy of temperance purely on scientific and moral grounds.

I am, Sir, yours &c.,

Bristol, Nov. 13th, 1880.

TEMPERANCE.

* * * This discussion must now close.—ED. L.

HYPODERMIC INJECTION OF MORPHIA IN CHOLERA.

Mr. Chas. MacDowall wishes to correct an error in his letter published in our columns on the 16th ult. The word "cases" should, he says, have been put in the singular number.

Mr. D. A. Gresswell.—Our correspondent, by referring to THE LANCET of Nov. 13th, page 795, will find that his request has been already complied with.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Bristowe, London; Mr. Brodhurst, London; Dr. Godson, London; Dr. Coleman, London; Dr. Barton, Fulbeck; Dr. Burton, Liverpool; Mr. E. SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....	£1 12 6	Six Months.....	£0 16 3
TO CHINA AND INDIA.....	One Year,	1 16 10	
TO THE COLONIES AND UNITED STATES..	Ditto,	1 14 8	

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings. Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be addressed at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom. The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers. Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Clinical Lecture

ON THE

INTERDIAGNOSIS OF INSENSIBILITY
FROM VARIOUS CAUSES.By REGINALD SOUTHEY, M.D. OXON., F.R.C.P.,
PHYSICIAN AND LECTURER AT ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—Questions somewhat of the following kind are likely to be put to you one day, and are full alike of clinical interest and medico-legal importance:—What is the matter with an individual who has been picked up on the road insensible, irrational, or inarticulate, and about whom no antecedents whatever are known? Is he ill, drunk, drugged, suffering from brain concussion, or from coma after an apoplectic or epileptic fit?

Syncope, trance, catalepsy, and coma are names severally used by medical writers to designate states of insensibility which the lay public group vaguely under fits.

Syncope is fainting; it may be otherwise described as a condition of body in which there is a death-like pallor, with loss of muscular power and of consciousness. Trance is a state of death-like faintness in which, however, some consciousness is retained, although the person is unable to move or speak. A faint is ordinarily (when an individual has not lost a very large amount of blood) an exceedingly transitory affair. A person collapses rather than falls to the ground in a faint; his knees bend under him, he subsides into the sitting posture, his head drops forward, and by the time the head has thus sunk to the level of the heart, or below it, the circulation through the brain becomes sufficiently restored for consciousness to return. In a faint a person seldom bruises his face. Upon waking up he may feel sick or giddy, or alarmed, but his brain resumes its thinking function usually at once and entirely.

In states of trance—of which I possess no personal experience, but may refer you to accounts to be read in Smith's "Forensic Medicine," pp. 540-542, and Forsyth's "Medical Jurisprudence," pp. 125-130, 155, and pp. 165-188—it appears that the body is to all appearance inanimate, and there is no power to move a muscle, the limbs meanwhile remaining perfectly flexible. The peculiarity attached to this condition is that the individual may hear, see, and remember all that goes on about him. There is no perceptible pulse or respiration, and hence trance has been mistaken for death, but we possess no recent or philosophical observations upon this form of faint. The recorded cases do not tell us of the temperature, or whether or not the muscles react to galvanic stimulus. Burial alive in this condition, except at sea, is highly improbable, but in no case would you be justified in making a post-mortem or consigning a body to burial unless you were satisfied from the presence of rigor mortis or appearances of putrefaction that death was actual. Catalepsy, again, is a rare inanimate condition; still I once had a case under my care which accorded well with the descriptions that have been given of it.

A young man of nineteen was picked up in Fleet-street insensible, not fallen, but standing stiffly, unable to move or to articulate. Here are the features that distinguish this state, all which he presented in other similar seizures which he had for several days afterwards while in the hospital. Thus while carrying something about, or sitting up in bed, or attempting to poke the fire, his eyes would suddenly acquire a fixed gaze, and he would remain arrested as it were in his act. We could set his limbs in any posture we pleased, and there he remained like a mesmerised cock, to the amusement of the nurses and other patients. I watched him on several occasions. There was not the slightest twitching or spasm of any of his muscles. His pulse was slow, and so were his respirations, his extremities cold and flabby, the axillary temperature remained natural. He would bear pinching or pricking without flinching, and took no account of our bawling his name close by his ear. There was no reason to think that he was feigning, and it

No. 2988.

would be difficult, I fancy, to feign and act a disease so well as he did. To quote from Dr. Copland's Dictionary, vol. i., p. 292: "The statue-like appearance and muteness of the cataleptic alone suffice to distinguish this disease. There is neither the lividity of asphyxia, the pallor and general flexibility of syncope, the stertor of coma, the paralysis of apoplexy, nor the movement and dreamy mental automatism of somnambulism."

Coma, however, because arising from very various causes, is the single one of the several states mentioned by them as likely to offer much difficulty in diagnosis. Coma may be due—1st. To pressure exercised on the brain, arising (a) from within the ventricles, effusion therein; (b) from depressed fracture; (c) from effusions outside the brain between hair and membranes. 2nd. To alteration in molecular state of brain from some concussion, contusion, bruising, œdema, apoplectic extravasation. 3rd. To brain poisoning by insufficiently oxidised blood, uræmic blood, narcotics, anæsthetics, inebriants.

I cannot give you certain symptoms for diagnosing each of these causes of coma, but I may aid you in excluding some of them, and thus help you to arrive at a correct diagnosis in particular instances. The profound coma produced by serous effusion into the ventricles of the brain, to judge from what I have seen in dropsy, renal or cardiac, and by what happens in tubercular meningitis, is gradually reached through a stage of sopor. The individual at first is sleepy, then dreamy and slow of apprehension, difficult to awake, and finally incapable of being roused at all. Reflex movements may be excited for a while, later the face is pale, the temperature falls. The breath is either Cheyne-Stokes or principally diaphragmatic and stertorous. At first there is power to swallow, afterwards acts of deglutition fail to be coördinated. The pupils are non-characteristic, but more often dilated than contracted. (a) The coma due to depressed fractures, or to effusion of blood or pus or fluid between the brain and the membranes, is as sudden in its advent as its cause may have been. Usually the breath is stertorous, the pupils are contracted, and the temperature is normal or above normal, the skin perspires profusely. No or only slight reflex response is made to galvanic or cutaneous stimulation.

You will be guided to the diagnosis of fractured skull by bleeding or oozing of bloody serum from the ear or nose, or by ecchymosis of the eye, and towards large apoplectic effusion of blood upon the surface of the brain by the stertor of the breathing and complete absence of reflex irritability. (b) When the coma is due to alteration in the molecular state of the brain, local contusion, or apoplectic extravasations, the face is usually pale, the temperature fallen below normal; the reflex irritability, although variable, is apt to be greater on one side of the body than on the other; the pupils may be unequal, and evidence of some hemiplegia is generally discoverable in muscles of the face or eye.

It seems like hair-splitting in diagnosis to dwell upon what may aid you to distinguish between coma due to general compression of the brain substance and coma due to more localised brain injury, with general circulatory and nutritional disturbance, but I give you the best clues I can, such as have served me sometimes well; the evidence of any hemiplegia in a case of profound coma is always in favour of localised injury of brain rather than of general pressure.

The coma may, however, be due to some brain-poisoning, the sources of which I have grouped under heading 3. Now, deficiency of oxygen and excess of carbonic acid in blood produces coma, as, for example, in the inhalation of laughing-gas or nitrous oxide, when the face is black, the veins turgid, the skin hot, the muscles irritable, and reflex spinal irritability is heightened.

Again, the blood-poisoning may be due to the action of some gas inhaled which interferes with or arrests the oxygen-carrying properties of the blood-cells. Sulphuretted hydrogen and carbonic oxide both appear to act in this way. The circumstances of the accident, the conditions under which the person was found, as well as some significant clinical appearances, already discussed by me, should facilitate the recognition of this source of coma. This blood change, if profound, is not recovered from.

Brain-poisoning and coma by anæsthetics and inebriants are usually detectable by the odour of the breath of the comatose person.

You may occasionally feel a little uncertain as between

apoplexy and dead drunkenness. We had an illustrative case the other day in our wards. A man who had been intoxicated by rum was admitted, and very profoundly comatose he was. No reflex movements were excitable; his face was cyanotic; there were gurgling râles in his throat, and I believe he might have died suffocated if I had left him in the position in which the nurse had placed him in bed, for he had a large tongue and uvula, with somewhat swollen and oedematous fauces; and as he lay on a flat bolster, with his head back, his tongue slipped back in his mouth, and nearly closed the opening of the glottis. Propping him up with a bed rest, and pulling his tongue forwards, his breathing quickly improved, and his face assumed a less blue colour. Still for some ten minutes I was unable to get any movement of either leg by tickling the soles of the feet, and the pupils were unequal, one rather smaller than the other, and both quite irresponsive to the stimulus of light. It was true he smelt of liquor, but he was quite properly admitted by the house-physician, since treatment and lapse of time alone could decide whether his coma was due to alcohol alone, or to disease *plus* alcohol. You may remember what I ordered in that case, as a piece of practice which is prompt, rational, and attended by no possible risks—the throwing up the rectum of a pint and a half of cold water, with a tablespoonful of common salt dissolved in it. It brought him out of his profound coma at once, for he asked for a night-stool almost directly afterwards. The stomach-pumping and belabouring with a galvanic battery of a comatose person, who may be the subject of gravescent apoplexy, belong to the surgery of the past, when active practice corresponded too closely with lynch-law-like punishment.

In every case of coma count the respiration, observe the quality of the breathing, and its ordinary effect upon the blood by the colour of the lips. Examine the pulse carefully for quality, frequency, regularity. Touch the eyeballs, examine the pupils for reaction to light, their condition—dilated, contracted, unequal, irregular; tickle the soles of the feet, to test what amount of reflex muscular action can be coördinated. The breathing in most states of coma is heavy and slow; notice if it be stertorous, Cheyne-Stokes-like, wholly diaphragmatic, or if the intercostals act. Next take temperature in the axilla or rectum. A remarkably low temperature, four degrees or more below normal, betokens usually uræmic coma, acetonæmia, or grave concussion of the brain. After epilepsy, apoplexy, intoxication, the temperature is more often normal, or even slightly above normal.

Uræmic coma will again be separately distinguished most often by some slight oedema of eyelids or extremities, wax-like pallor, bronchitic sounds, very foul breath, smelling of beef-tea; a brown furred tongue, pearly conjunctivæ, and dilated pupils bespeak urea poisoning. Diabetic coma is indicated by oppressed noisy breathing, effected by abundant muscular effort, but attended by some lividity in evidence of impaired oxidising changes at the pulmonary capillaries, of which we do not at present understand the exact cause.

In the coma that has succeeded an epileptic fit you may expect to find bruises, torn or dirtied clothes, indications of the tongue having been bitten.

Finally, the mode of recovering consciousness after intoxication differs much from what is observed in persons recovering from the coma that succeeds an epileptic fit. After intoxication I have noticed that while the sense of hearing is recovered soon, the lower attributes of mind, the sensorial instincts, reappear early, the individual who was comatously drunk hears correctly before he sees correctly, and sometimes before he can stand. It is curious to notice the manner in which he repeats a word of your question over and over again, like a parrot, and perceive how some grotesque idea grows out of the jingle or jangle of a phrase mumbled over more or less thickly.

How differently do the mental faculties recover after brain concussion and commotion as after epilepsy. How the intellectually reduced “*égomet*” is in a dreamy state and staggers in his gait, hears questions put to him correctly, answers them articulately, apparently rationally, but having done so straightway forgets what he has said, cannot tell where he is or what he is or was doing. He is conscious of some confusion in his own memory, and shows often some high measure of judgment in his distrust of himself, and says: “I cannot recollect where I was going.”

Intellectual wholeness or sanity lies outside to-day’s

lecture, and I mention this merely as a clue to past coma, whether from drink or cerebral commotion.

It remains for me to point out the distinctive features of opium coma. There is profound stupor, with closed eyelids, contracted pupils, upturned eyeballs; the face is pale, the skin cool, clammy; the forehead beaded with heavy perspiration; the limbs are lax, but, for a while, reflex motions are readily excited. The respiration now slackens, falls in frequency, perhaps, as I have seen it do, to as low an ebb as 6 per minute, the pulse remaining fair at 80. The coma now is very profound; you may prick, stimulate by galvanism, call, flick, stimulate by what means you please, little or no further purposive response is returned by coördinated muscular movements. The body will not walk; it is only dragged about, if the advice given has been to walk the man about. Next the lips get livid; the surface of the body colder; the breath is sobbing, and at long irregular intervals; the pulse hardly to be felt at the wrist, and death is imminent by asthenia or sudden failure of the heart’s action. Now for what may you mistake this coma, and what may be most easily confounded with it? Apoplexy into the pons Varolii, since, as was pointed out long since by Dr. Wilks, who illustrated the fact by several examples of cases that had fallen under his observation, apoplexy into the pons is attended by great contraction of the pupils.

If, then, in any case of profound coma, with extremely contracted pupils, you suspect opium to be its cause, but have no corroborative fact, no laudanum bottle, no opium-smelling substance, or mark of subcutaneous morphia syringing upon the body, or soot of opium-smoking inside the nostril to aid you, remember that the case may still be apoplexy into the pons, a source of coma not likely to be benefited either by bastinado, beating with towels, walking about, or all the extracts of coffee which can be pumped into the body at either extremity.

Clinical Lecture

ON A

CASE OF STRANGULATED HERNIA.

Delivered at Westminster Hospital

By GEORGE COWELL, F.R.C.S.,

SENIOR SURGEON TO THE WESTMINSTER HOSPITAL, AND LECTURER ON SURGERY.

GENTLEMEN,—The patient, Richard M—, whose case I bring before you to-day, was admitted into Northumberland ward on Wednesday, May 5th, with urgent symptoms of a strangulated left oblique inguinal hernia. He is a spare, thin, nervous-looking man, forty-two years of age, and by occupation a groom. The history that he gave was this. The hernia first appeared in the left groin about twenty years ago, coming down suddenly whilst he was jumping a fence. The size of the rupture was described as that of a pigeon’s egg, and the patient succeeded in reducing it himself about four hours after it had appeared. He was very properly advised to get a truss, and he seems to have worn it for about six months, when he left it off, supposing that his rupture was cured. The fact that the hernia did not return for nine years shows the immense importance and advantage in such cases of the immediate application of a properly-fitting truss. On its recurrence after this interval the patient states that he again succeeded in returning it, and that he resumed his truss. About two years ago the breaking of his truss led to his discarding it, and shortly afterwards the hernia came down whilst the patient was riding, and this time he failed to reduce it. He was admitted into the Great Northern Hospital, where he remained for three days. All attempts to reduce the hernia failed, and symptoms of pain and vomiting rapidly ensued. However, on the third day, when in a warm bath, the patient succeeded in reducing the hernia himself, and the symptoms ceased. His truss was repaired and resumed.

About the same time a small, easily-reducible hernia, appeared in the right groin.

On the morning of the 5th of May the left hernia came down, the patient says, without any straining or exertion, and a few hours before midnight he presented himself at the Westminster Hospital with a large inguinal hernia of the left side, with some symptoms of strangulation, considerable abdominal pain, and vomiting. The house-physician, who was acting for the house-surgeon, placed the patient in a warm bath, and reported that whilst applying the taxis he felt something go up, but found it impossible to reduce the bulk of the rupture. The patient was put to bed, an ice-bag was applied to the tumour, and two grains of opium administered. The pain, however, continued during the night, there were great restlessness and continual retching and vomiting, and at 7 o'clock the next morning (June 6th) I was called to the case.

The face of the patient then presented an expression of extreme anxiety; the pain appeared to be intense in the neighbourhood of the inguinal canal and about the umbilicus. The rupture itself was soft and doughy, and evidently the greater part of its contents was composed of omentum. This fact was made out more fully when the patient had been placed under the influence of ether, and as it was found impossible to reduce the size of the tumour by the taxis the operation was proceeded with. The incision was made over the neck of the sac; the coverings of the hernia, which were very thin, were opened in the usual way, and the seat of stricture was divided. Still no return of any of the contents of the hernia could be effected, and it was found necessary to open the sac. There was no fluid in the sac, and no intestine to be seen. At the neck of the sac, however, was a very small portion of intestine, which at once slipped through the constriction on the pressure of the finger introduced into the sac. All the rest of the contents was omentum, a small portion of which was adherent to the interior of the sac. It was found impossible to return more than a very small part of this omentum, and it was removed, with the exception of a small portion that was adherent. This was left in the hope that it might form a plug for the sac. The plan adopted for the removal was the application of a number of catgut ligatures (six) to the various portions of the omentum; the mass was then cut off, and the stump of the omentum gently passed in detail within the abdominal cavity. The wound was closed with three sutures, and dressed with lint dipped in carbolic oil, and the usual pad and bandage were applied. The patient was then placed in bed, and was ordered to take fifteen minims of tincture of opium every four hours. He had ice to suck, and later, beef-tea was administered, a teaspoonful at a time. Throughout the day he was free from his previous symptoms.

May 7th.—The patient had passed a somewhat restless night, and this morning there had been some return of the retching. There is slight tympanites. The temperature is normal. Effervescing mixture with dilute hydrocyanic acid was given in addition to the opium.

The retching, with occasional vomiting, continued for several days. On the 10th a small hernia was discovered at the umbilicus, the patient having called attention to pain which had come on during the night whilst vomiting. He stated that he had previously had a similar hernia at the same spot. It was not strangulated, as it could be emptied, but it could not be reduced until two days later. Meanwhile the restlessness and vomiting increased, delirium came on, and it was with great difficulty that the patient could be kept in bed. There was no increase of the tympanites. Hypodermic injections of morphia were substituted for the opium, and on the 11th a turpentine enema was administered. This was followed by a moderate evacuation from the bowels, the first since the operation. The symptoms did not cease until about six hours after the reduction of the umbilical hernia on the 12th. From the cessation of the vomiting the patient made an uninterrupted recovery. He was not allowed to take solid food until the 21st, the fifteenth day after the operation, by which time the wound was almost healed. He has now been furnished with a well-fitting double truss, and leaves the hospital to-day (June 10th).

There are several points about this case which are both interesting and instructive. The rapidity with which the symptoms of strangulation showed themselves on more than one occasion, and the extreme severity which these symptoms assumed within less than twenty hours of the reputed descent of the bulk of the hernia, are fortunately not very

frequent, and would seem to depend upon the existence of a temperament of extreme nervous irritability; but when severe symptoms do rapidly occur, they must be met with a similar promptness on the part of the surgeon. Many more lives are lost by postponing the operation too long than by an undue haste to perform it. When once the surgeon is convinced that a hernia is strangulated, and that he cannot reduce it by ordinary means, every hour that the operation is postponed increases the risk of the patient. There is one class of cases, however, where great care is required lest an operation be too readily and needlessly undertaken; I mean in cases of inflamed herniæ. It must not be forgotten that all or most of the symptoms of strangulation may be produced by the presence of inflammation in a hernia, and even by enteritis. In the former case the hernia would be tense, painful to the touch, and irreducible; and the latter condition might coexist with an irreducible hernia. The symptoms in both cases might, without care, be taken for symptoms of strangulation, and operative interference would almost certainly be attended by a fatal result. In the present case inflammation was certainly not the cause of the symptoms; the hernia had been down too short a time, and showed neither tension nor tenderness.

Although the bulk of the hernia was omentum, still the severity of the symptoms rendered it probable that some portion of intestine was strangulated. I remember a case that was under my care in Queen Anne ward ten years ago, and which is reported by Mr. Hothouse in his book on "Hernial and other Tumours," where the patient, aged seventy, had an old irreducible femoral hernia, composed chiefly of omentum, but who died (she refused to be operated upon) with a strangulation of an exceedingly small knuckle of intestine which had found its way into the neck of the sac. This proved to be the case in the present instance, and it is probable that the shape of the omental mass rendered all attempts to reduce the strangulated intestine nugatory until the sac was opened and the finger could be passed within it to its neck.

The manner of dealing with the omentum was perhaps novel. The usual plan is to apply a ligature round the mass, and by means of it retaining the stump in the neighbourhood of the inguinal canal when it has been reduced, in order that the discharge from it may escape by the wound, and that it may form a permanent plug. Instead of this, I tied the omentum piece by piece with several ligatures of carbolic catgut, cut them off short, and trusted to the portion which was adherent to the sac, and which I did not interfere with, to retain the stump of omentum, or at all events one end of it, in the neighbourhood of the inguinal canal. This plan appeared to be more suitable in the present case, and certainly the omental vessels were more effectually secured separately. It is too soon to say if the result will be the obliteration of the sac by inflammatory adhesion, but at present there seems to be a firm cord occupying the position of the sac.

The remaining point of interest to which I will allude was the presence of three herniæ in this patient, and the complication which the occurrence and difficulty of the umbilical hernia produced during the progress of the case. It is difficult to say in what proportions the inflammation of the portion of intestine which had been strangulated, the subacute peritonitis, and the umbilical hernia severally contributed to maintain the retching and vomiting that recurred twenty-three hours after the operation, and persisted for so many days. The first two conditions probably were the primary cause of that recurrence, but there is no doubt that the delay in reducing the small umbilical hernia was a very material element in the persistence of those disagreeable and dangerous symptoms.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Miss Jessie Landseer, late of Kensington Park Gardens, bequeathed £100 each to St. Mary's Hospital, the Brompton Consumption Hospital, the Middlesex Hospital, the Metropolitan Free Hospital, the Hospital for Sick Children, Great Ormond-street, the West London Hospital, the Westminster Hospital, the London Fever Hospital, the National Hospital for the Paralysed and Epileptic, the British Home for Incurables, and the Royal Hospital for Incurables. The Goldsmiths' Company have given £50 in aid of the funds of the Royal Hospital for Children and Women, Waterloo-road. The Mater Misericordiæ Hospital, Dublin, becomes entitled to a sum of £375, and £175 yearly, by the will of the late Very Rev. Anthony Magee, of the Priory, Clifden, Co. Galway.

ON "TENDON-REFLEX" AS AN AID TO DIAGNOSIS IN DISEASES OF THE SPINAL CORD.¹

By THOMAS BUZZARD, M.D., F.R.C.P.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

(Concluded from p. 844.)

WE have now to suppose the case of the patellar tendon-reflex being absent in a patient who is either entirely confined to his bed or only able to walk with some difficulty. The quadriceps extensor is found more or less wasted, we will say, its response to induced currents being either below the normal standard of excitability or lost altogether. In the latter case there will be inability to contract the muscle by voluntary effort. Such a condition necessarily indicates that the muscle is cut off to some extent by some means or other from the trophic influence of the spinal cord. The seat of this influence is known to be in the large ganglion-cells which lie in the anterior horn. Now, it will be seen, if we look at the diagram (Fig. 3), that the interruption in this

FIG. 3.

case may exist either in the anterior root outside the cord, the short portion of it within the cord, or in the anterior horn of grey matter itself. As regards the second of these possibilities, nothing is known for certain that will enable us to localise lesion in that particular portion of the anterior root. For the rest, absence or marked decrease of reflex, along with muscular wasting and loss of faradaic excitability, may be caused by neuritis of a mixed spinal nerve, or it may result from spinal meningitis, involving the anterior roots either alone or in conjunction with the posterior roots. The precise cause for the interruption in such a case can only be determined by the consideration of collateral circumstances, into which I need not enter at length. It may be remarked, however, that if the symptoms described are accompanied by pain and tenderness in the nerve trunk, and some cutaneous insensibility, this sensory disturbance makes it evident that the cause of interruption is in the mixed nerve (in which the motor and sensory roots are combined), and not in the anterior (motor) root alone. I have recorded cases of neuritis in which marked decrease of tendon-reflex occurred in these circumstances.² All that is sure from percussion of the tendon and examination of the muscle is that a break exists somewhere on the motor side of the nervous arc. Nor may there be anything in the condition of the muscle in such a case to distinguish it from that which obtains when the break in the nervous arc is brought about by atrophy of the large ganglion-cells in the anterior horn. In the rough diagram (Fig. 4) it is seen that the line, indicating the nervous arc, passes through an anterior horn which is shrunk and atrophied, and in which there is but little trace of ganglion-cells to be observed, in striking contrast to the number and size of those in the anterior horn of the other side. In this shrunken anterior horn, then, the

"fault" occurs which causes absence of tendon-reflex. Now atrophy of the ganglion-cells of the anterior horn occurs in various conditions. It often happens as part of a diffuse myelitis, involving not only the anterior horn, but more or less completely the whole transverse section of the cord. In the acute atrophic paralysis of infants and adults (polio-myelitis anterior acuta, commonly called infantile paralysis), there is acute myelitis, which is practically confined to the anterior horn of grey matter. In this disease the loss of faradaic excitability of the muscles is very constant and marked. In the chronic malady, however, in which the same

FIG. 4.

structure is affected (progressive muscular atrophy, protopathic amyotrophy—Charcot), it is somewhat remarkable that, as Duchenne has shown, no decrease of faradaic excitability is to be noticed in the muscle. (This is no doubt the rule, but I have seen exceptions to it.) In the former case apparently a mass of ganglion-cells is suddenly, or at least very rapidly, subjected to a change which arrests their function, and which is followed by atrophy of more or less of their number, of which a varying proportion recovers. In the latter disease it would seem as though, in consequence of a slowly creeping lesion, the ganglion-cells atrophied gradually, leaving those of them which are spared unaltered, or at least with their function unimpaired, until they in their turn are invaded and destroyed. The relation of tendon-reflex to progressive muscular atrophy is a good deal complicated by the circumstance of there being at least two classes of this affection—the protopathic amyotrophy and the deuteropathic amyotrophy of Charcot. In typical cases the former is a very slowly progressive muscular atrophy, the gradual loss of power of the patient being in proportion to the extent to which the anterior horns of the cord have been invaded and the muscular system correspondingly atrophied. The latter begins with loss of power (paralysis) independent of muscular atrophy, and is succeeded by a rapid muscular wasting of some or all of the muscles previously paralysed. It is this form which tends to extend into the medulla oblongata and to occasion death by destruction of the ganglion-cells essential to life, which are continuous upwards with those of the anterior horns of the spinal cord. The duration of this form is much shorter than that of the other. In the protopathic form the tendon-reflex may exist, to some extent at least, for a certain time, to be lost, however, when the atrophy has advanced, so that it is impossible to say that the behaviour of the tendon-reflex is at all characteristic. The break which causes its absence in such a case is in the anterior horn, as in Fig. 4.

The condition of the tendon-reflex in the deuteropathic form is extremely interesting. Before considering it, however, I should like to draw attention to Fig. 5. In this diagram there is a rude representation of sclerosis of a lateral column of the spinal cord. In a previous diagram (Fig. 2) the position of sclerosis of the posterior root-zone was indicated. It was shown that if the afferent fibres from the tendon go, as we believe they do, with the sensory roots, they pass through the outer part of the posterior column, and consequently are exposed to a lesion which produces atrophic changes in them. The nervous arc is therefore "cut" at this point, and that absence of tendon-reflex results, which is so conspicuous a feature of tabes dorsalis. The position of sclerosis of the lateral column, which we are now considering, is, it will be observed, altogether outside the nervous arc by which we

FIG. 5.

¹ In the preceding portion of this paper, published last week, I referred to a case of hemi-paraplegia under the care of Dr. Ramskill, and after mentioning that there was paralysis with extensive wasting of the left lower extremity, and anesthesia (without any motor complication) in the right lower extremity, I went on to state that the patellar tendon-reflex was absent in both legs, and attributed its disappearance in the right limb to the fact that the lesion of the cord, although probably to a large extent confined to the left segment, was not absolutely so. I thought that it encroached a little upon the right half of the cord, far enough to interfere with the integrity of the grey matter to a certain extent without affecting, however, the anterior horn. I ought to have mentioned that this view, which appears to me to be necessary in order to explain the break in the nervous arc subserving patellar tendon-reflex in the right limb, is supported by the existence of a patch of cutaneous anesthesia, about eight inches by four, in the neighbourhood of the left great trochanter.

² THE LANCET, April, 1879.

suppose the stimulus from the tendon to the muscle to be transmitted. We should expect, therefore, to find that in sclerosis of a lateral column the tendon-reflex would not be absent. And that is the case. The tendon-reflex is never lost as a result of uncomplicated sclerosis of a lateral column.

So far from being lost, the tendon-reflex is indeed increased, frequently to a very surprising extent. Ankle clonus (also knee clonus—Erb, Gowers, Waller) may be, in these circumstances, produced not only (in the case of ankle clonus) by sudden dorsal flexion of the foot,³ but by the patient's own movements, as well as by light blows on various structures (bones, muscles, tendons), and sometimes even by the slight vibration produced by an accidental jar of his bedstead. This excitability to various kinds of stimulation is, however, by no means constant. One sees in certain cases of lateral sclerosis something like the converse of what I have described as occurring in tabes. There is excessive tendon-reflex, knee clonus, as well as ankle clonus, yet the muscles concerned will not respond to a blow, and need a distinctly stronger faradaic current than in health to cause their contraction.

The question of prognosis is so mixed up with that of diagnosis in regard to the occurrence of ankle clonus, that the two may be considered together. The facts appear to show that in all cases the occurrence of increased tendon-reflex in anything like a marked form signifies that from some cause the inhibitory influence of the higher centres is no longer being normally excited. It always means apparently that something has come in the way (at some point or other) of the natural propagation of nervous impulses from above. It is generally accepted that impulses from the highest centres (so-called volitional impulses) travel to the ganglion-cells of the anterior horns by the antero-lateral columns of the cord (pyramidal tracts). The fact that by what is commonly called "an effort of the will" we can control to a certain varying extent the reflex actions which are subserved in different parts of the cord would seem to show that in all probability the restraining influence which is continually and unconsciously being exerted over certain spinal reflexes in a state of health is conveyed by this same channel.⁴ Now it is when these (antero-lateral) columns are most extensively invaded by sclerosis, that is to say, when the resistance to the propagation downwards of nervous impulses from above is greatest, that we obtain the most marked ankle clonus. When there is a history pointing to myelitis at some portion of the cord, followed by a more or less pronounced rigidity of the limbs, with excess of tendon-reflex which has existed for some considerable time, say upwards of a year or two, we shall hardly be wrong in assuming that a change has taken place in the lateral columns which is likely to be permanent. And so also in reference to the like symptoms often consequent upon an attack of hemiplegia. An excess of reflex combined with more or less rigidity of the limbs, if it has lasted for months, may be considered as indicating a structural change in the lateral column which is unalterable. But this is by no means the case when the symptoms have not been of long standing. I have under my care at the present time in hospital a young woman who came in last June on account of paraplegia of ten months' duration, referable, as it seems, to a subacute myelitis in the dorsal region of the cord. On admission there was such a spastic condition of the legs that they contracted when handled or upon any attempt being made to flex the joints, which were stiff. There was great excess of patellar tendon-reflex, and ankle clonus was readily produced in a marked degree in each foot. The patient has gradually improved. She can stand and walk with very little help. There is no longer any marked spastic rigidity, and ankle clonus cannot now be obtained in either foot.

In hysteria the tendon-reflex is, so far as I have yet seen, usually increased, and in several cases I have witnessed the occurrence of ankle clonus, the possibility of producing which has entirely, and in one case suddenly, ceased on the patient's recovery. I submit that this fact is an

extremely important one in reference to the causation of the phenomenon. There would seem to be but little doubt that in hysterical paraplegia the cerebral influence which is propagated downwards in health by the antero-lateral columns of the cord is more or less in abeyance. It may be suggested that the reason why an hysterical girl does not walk is because the nervous impulses from above, which ordinarily act upon the various spinal centres for progression, do not arrive there. The absence, then, of impulses downwards through the lateral columns seems to result in an effect upon the tendon-reflex which is very similar to that occasioned by the resistance to their propagation through the columns which is interposed by the structural change occurring in sclerosis.

It is necessary to remark, then, that the existence of ankle clonus cannot be considered conclusive evidence of a structural lesion of the spinal cord. It may be, to use a term which is generally understood, although scarcely capable of exact definition, "functional." I have never seen, however, in a case of hysteria an excessive degree of ankle clonus. The automatic flexion and extension movements of the foot will go on for perhaps a dozen times, becoming gradually weaker, and ceasing spontaneously.

The behaviour of the tendon-reflex in deuteropathic amyotrophy (lateral amyotrophic sclerosis) is important. Even when the disease is tolerably far advanced, and a good deal of atrophy of the muscles has taken place, it will be often found that the tendon-reflex not only remains, but may be in some excess. I have a patient now under observation who presents a typical example of the disease. He cannot stand without help, and the muscles of his thighs are not only much wasted, but their faradaic excitability is diminished, and they hang flabbily from his bones. Not only is the patellar tendon-reflex, however, in excess, but there is some ankle clonus occurring when he plants his foot in certain positions. I would suggest the following as an explanation of such cases as these (Fig. 6). So long as a certain number

FIG. 6.

of ganglion-cells remain intact in the anterior horn the nervous arc (for tendon-reflex) is complete. Now, if the lateral columns were sound, the inhibitory influence from above transmitted by them would be potent enough to hold the reflex, in its necessarily diminished strength, in complete restraint (as, for example, in infantile paralysis), and no response would therefore occur to a blow on the tendon. But the lateral column is diseased; the check is consequently removed, and the reflex manifests itself often with great energy. As a matter of course, however, it is not so strong as in that form of lateral sclerosis which is unattended by muscular atrophy.

In an earlier part of this paper I have remarked that the response of the quadriceps to a blow on the patellar tendon "almost always signifies that the nervous arc is not seriously interrupted in that part of the spinal cord which gives origin to the lumbar plexus." In such a case as we are now considering (lateral sclerosis with muscular atrophy), it is evident that now and then the tendon-reflex may be apparently normal, and yet the spinal cord at the part which is concerned be affected with atrophy of some of the ganglion-cells in the anterior horn. The defect in the reflex mechanism is, as it were, just balanced by the defect in the mechanism which restrains reflex. It is necessary to bear this possibility in mind, in order to avoid an error, which, however, a little inquiry into the collateral circumstances will easily prevent.

³ I would refer to a lecture of mine in THE LANCET, Aug. 10th, 1878, for a detailed description of this phenomenon.

⁴ Dr. Hughlings Jackson believes that the rigidity in hemiplegia results because by atrophy of the fibres of the lateral column of the cord "cerebral influence" is taken off from the anterior horns, and thus the "cerebellar influence" upon them is no longer antagonised. On this principle, too, he would explain the increased tendon-reflex in cases of hemiplegia; *mutatis mutandis*, as regards lesions taking off the influence of the cerebellum.

ON CHIAN TURPENTINE AND ITS USE-
LESSNESS IN CANCER.

By HENRY MORRIS, M.A., M.B.,

SURGEON, AND SURGEON TO THE CANCER OUT-PATIENT DEPARTMENT, OF THE MIDDLESEX HOSPITAL.

(Concluded from p. 846.)

CASE 5. *Carcinoma of uterus and vagina; death.*—Janet M—, aged sixty-five, was admitted to Stafford ward, June 24th, 1880. A widow and the mother of seven children, the youngest thirty-five, the eldest forty-five; five born prematurely; no miscarriages; catamenia commenced between thirteen and fourteen, always regular till fifty-four. General health always good. No cancer in family. About twelve months ago she noticed a little hæmorrhage, which recurred from time to time, but never in great quantity. Has not markedly lost flesh. Was operated upon at Soho-square Hospital in January, 1880. Thinks chloride of zinc was applied. Became an out-patient at the cancer department of the Middlesex Hospital on April 15th, and continued till admission on June 24th.

Vaginal examination.—Os and greater part of cervix quite gone, and in their place a large, irregular, horny ulcerated growth, with indurated edges, which extends a little way along the posterior wall of the vagina, and further still along the anterior wall. The upper part of the vagina, where it joins the back of the uterus, gives to the finger the impression of a deeply-excavated, irregular chasm. Discharge abundant, offensive, and watery. Is a very emaciated woman, with pinched look, but no marked cachexia. Spirits good; sleeps well; appetite fair; bowels very confined; micturition sometimes difficult, but never very painful. Suffers but little pain.

She was at once placed upon the Chian turpentine mixture, taken three times a day. This was continued up to the 21st of August. During the first week in September there was diarrhoea. On September 7th the Chian turpentine mixture was resumed, and taken, with occasional intermissions, till a few days before death, on November 4th. From the end of September she suffered a great deal, owing to a fistulous communication between the rectum and vagina. Her distress on this account was, however, in great part relieved by injections of warm water, used daily, with the object of keeping the parts around the fistula clean. Occasionally antispasmodics and aperients were required in addition to the turpentine. Throughout opium pills were required at night occasionally; but during the last six weeks of life they were given at intervals during the day as well as at night.

Necropsy, by Dr. FOWLER, fifteen hours after death.—Body very emaciated, abdomen retracted. No recent peritonitis. The uterus was almost entirely destroyed by cancerous ulceration, which extended down the vagina to within one inch and a half of its orifice. The rectum had been opened about two inches and a half from the anus by extension of the ulceration. The bladder was not invaded, and was normal. The kidneys were normal, as were the other organs.

CASE 6. *Cancer of the uterus; death.*—Sarah Jane D—, aged forty-seven, a widow, mother of eight children, and engaged as a mission woman. Applied to the cancer out-patient department on April 22nd. She had suffered from occasional pain and discharge for two years and a half. Since December, 1879, has had a constant watery discharge, much pain, and from time to time flooding.

She was treated by tonics, anodynes, and disinfecting injection until May 13th, when Chian turpentine mixture was commenced. At this time ulceration of the os and cervix uteri was well marked, and she had a great deal of watery discharge.—July 1st: Still continues taking the Chian turpentine. There is now a clean, but irregular, ulcerated surface, with indurated edges. She complains much of pain in the right groin, but has had no flooding and much less discharge. One evening, shortly after this visit, having felt pretty well and in good spirits during the day, she suddenly called for the assistance of a neighbour on account of a profuse flooding. From this time she was

obliged to keep the house, rapidly became weaker, suffering agony up to within a week of her death, and died at the end of last August.

CASE 7. *Cancer of uterus, with profuse flooding.*—Elizabeth R—, aged thirty-eight, married, applied to the cancer out-patient department on June 10th. She had been ill nine weeks, and during that time had so frequently flooded, that on her appearance at the hospital she was reduced to extreme weakness, and presented a most marked bloodless appearance. She also complained of great pain in the back. There was a large sprouting ulcer involving the os and cervix of the uterus. She was anxious to know if she could safely take the journey to her dying husband in Germany, but her condition was so grave that I was compelled to forbid this, fearing at least that the effects of sea-sickness would be absolutely fatal.

She was treated with a mixture of ergot and cinchona, a morphia pill at night, and a belladonna plaster for the back. Under this treatment the bleeding stopped, and as a result she improved greatly in strength and looks.—Sept. 2nd: There has been no bleeding for some weeks, and there is but little discharge. She is altogether improved. Chian turpentine mixture was now ordered.—Oct. 7th: Has continued the turpentine for five weeks. The uterus is hard and enlarged, the os and cervix are at least five times larger in diameter than normal.—Nov. 11th: Is still under the Chian turpentine treatment, but there is no improvement in the state of the uterus. Her condition is extremely bad.—Nov. 22nd: Has been admitted to Stafford. The greater part of her vagina is filled with cancer growth.

CASE 8. *Cancer of the uterus, extending to the rectum.*—S. P—, aged fifty, the mother of ten children, came under treatment at the cancer out-patient department on June 24th, 1880. The os and part of the cervix uteri had disappeared. There was a wide irregular ulcer with thick edges, and surface crossed by hardened ridges; the posterior wall of the vagina at quite its upper part was thickened and deeply ulcerated. Her chief trouble was difficulty in defecation. Symptoms began with flooding and pain in April, 1880.

She was at once put upon the Chian turpentine mixture three times a day. There was flooding from the 10th to the 15th of July, and an excessive offensive watery discharge; constipation also troublesome. Sept. 9th: Flooding has been severe for fourteen days; suffers from frequent severe pains in the legs and pains of the character of labour-pains. Considers herself better for the mixture, and says she would be sorry to be without it.—Sept. 30th: Has taken the Chian turpentine regularly three times a day up to this date. Her sufferings are severe. To-day ordered Haust. Caryophylli Co. et Morphie twice a day, and to continue the Chian turpentine mixture twice a day.—Nov. 18th: Has continued the same treatment since September 30th, but she is much weaker, has shortness of breath and a cachectic look; is very anxious to be admitted, as she is unequal to her work. The vagina is thickened, and its lumen contracted about the middle by deposit in its walls; beyond the contraction is an ulcerated cul-de-sac. The fundus uteri is much enlarged and very hard. *Per rectum*, uterus is found greatly enlarged, hard, and irregular; there is infiltration of the anterior rectal wall and incontinence of fæces.

CASE 9. *Ulcerated scirrhus of the breast; death.*—Eleanor S— was admitted into Stafford ward on Oct. 15th, 1879, with an ulcerated cancer of the left breast. Married, but sterile. General health good. No cancerous history. Disease began about four years ago as a small lump the size of a marble in the outer side of the left breast; it gradually increased, and after twelve months the skin became affected, then ulcerated. The tumour discharged and then shrank, but cancerous infiltration extended up to the axilla. More or less pain suffered.—April 2nd, 1880: There is a large foul ulcer with induration around; the pain neither continuous nor severe. Chian turpentine pills were commenced, all other remedies being discontinued.—April 13th: No appreciable change.—16th: The discharge is greater in quantity, offensive, and not altered in character.—27th: Breast seems, on the whole, worse than formerly. There is more discharge, and some bleeding occurred this morning.—May 26th: Discharge considerable and offensive, pain severe.—June 10th: Had a fit this morning, attended with unconsciousness, sickness, and twitchings of the muscles of the face. It did not last long. Chian turpentine was continued regularly up to the first week in July, subsequently only at intervals and

less frequently. The disease slowly progressed, and she died, exhausted, on Sept. 11th.

CASE 10. *Ulcerated scirrhus of the breast; cicatrisation.*—Sarah W—, aged fifty-nine, a widow, applied at the cancer out-patient department on April 15th, 1880. Is a large-framed, stout woman, and the mother of four children. The cancer began as a tumour of the right breast five years ago, and after slowly increasing for two years ulcerated. When first seen there was a large circular ulcer, with thickened edges and foul, greyish, discharging base, in the sternal half of the mammary region, the remaining part of the mamma prominently enlarged. The ulcer is prone to bleed considerably at times, and she often suffers severe pain. A lotion of carbolic acid as a wash, a saturated solution of alum to be used if necessary to stop hæmorrhage, and the Chian turpentine mixture to be taken three times a day, were ordered.—April 22nd: She describes herself as having had no pain since commencing treatment.—July 8th: There has been a distinct improvement since she has been under treatment. There is much cicatrisation at the edges, and a healthy, purulent discharge from the surface of the ulcer.—Oct. 7th: A wide border of cicatricial tissue surrounds the ulcer, but in and beyond the cicatrix there is a ridge of indurated tissue due to fresh infiltration. There has been a diminution in the size of the remaining portion of the breast.—Oct. 21st: There has been more hæmorrhage again this week; continues with the turpentine mixture. She is still under treatment, but there is no further change.

Remarks.—If I had not seen cases of this sort before, I might certainly have believed that the turpentine had caused the cicatrisation.

CASE 11. *Ulcerated scirrhus of the breast; death.*—Mary Sarah R—, aged forty, widow, mother of three children, applied on July 22nd at the cancer out-patient department for ulcerated scirrhus of the left breast. Disease began three years ago as a small lump in the mamma, to the inner side of the nipple. When first seen there was a wide and offensive ulcer, involving the inner half of the breast. Nipple present and not retracted, the axilla stuffed with enlarged glands. On September 2nd she commenced the Chian turpentine mixture three times a day.—Sept. 9th: She considers herself better for the mixture. The whole surface of the wide, saucer-like excavation is covered with yellow felt-like secretion. She continued to decline, and on Oct. 21st was too ill to come and see me, but sent for more medicine. A few days later I heard of her death by letter.

CASE 12. *Nodular and rapidly-ulcerating scirrhus of the skin of the mamma.*—Mary Ann Y—, aged fifty, applied at the cancer out-patient department on Sept. 16th, with cancer of the skin over the right breast. Married, mother of five children, and had had four miscarriages. A stout, intemperate-looking woman; disease is said to have begun in March, 1880. When first seen there was a very large and wide area of ulceration, in patches, on the surface of a large and pendulous breast. Beyond this area there were several small pea-sized nodules (in places running into one another) in the skin, some of which were breaking down into circular, punched-out ulcers. The undestroyed skin between the ulcers was of a bright-red colour. A worm-eaten aspect was thus given to the parts. She used stramonium ointment and took quinine up to Oct. 7th, when the Chian turpentine mixture was commenced.—Oct. 21st: The number of cancerous warts has increased, and are spread over a wider area; fresh ulcers have formed by the breaking down of the warts, and present an ashy-grey slough at their base. A cuirass-like thickening is detected in the skin of the other breast. Eczema below the right breast, probably excited by the foul discharges. The stramonium ointment again resorted to on account of the severe pain, and a pill composed of two grains of extract of conium and three grains of extract of hyoscyamus to be taken every night, and in the daytime also if necessary. Chian turpentine continued.—Nov. 11th: The disease is still spreading widely; now around to the back upon the right side, as well as across the sternum over the left breast. There is a most offensive, loathsome odour with the discharge. Suffers much, and is very feeble: says she can no longer take the turpentine mixture, as it makes her sick, and begs to be put again upon the quinine treatment.—Nov. 18th: So ill, and altogether in such a bad condition, that she has been admitted to-day into Bird ward, instead of awaiting her turn for the cancer wards.

Of the foregoing cases eight are of the female genital organs, and four of the breast. Of the eight uterine cases five are dead, two are known to be extremely ill, and one after a short trial of the turpentine declined to continue taking it. This last is the only case in which the turpentine was not taken for several weeks in succession. Of the four breast cases two are dead; one is in the hospital, with the disease very rapidly advancing, and will probably not live many weeks; and the fourth is of that somewhat rare and chronic variety of scirrhus which, after ulceration, cicatrices, whilst fresh cancerous material is deposited in and beyond the cicatrix.

I might add notes of several other cases, both uterine and mammary, in which the turpentine has been given for many weeks, and even months, together, but without benefit.

I am not able to report that there is a single symptom over which the drug seems to exercise even frequently, not to say constantly, an influence. It cannot be relied upon to assuage pain, to diminish or alter the character of the discharges, to check hæmorrhage, or promote the destruction of the growth by ulceration or sloughing. In the few cases in which the patient at first thought she was benefited, the impression was due to that "clutching at straws" tendency, that is so often observed in persons suffering from lingering and incurable disease, and to her being encouraged to think that she was taking a new and certain cure. Rest, regulation of diet, attention to the bowels, an anodyne at night, and the extra local cleanliness which follows from the use of injections and lotions, will of themselves, and without any internally-administered drug, give temporary ease and improvement.

Besides, it must not be overlooked in observing the effects of drugs on cancer, that some cases of cancer seem to halt in their progress, and stand still for a longer or shorter time—nay, even more, they seem to retrogress. I have at the present time a man with a cancerous ring stricture of the rectum, who many months ago came to the cancer out-patient department emaciated, pinched, and haggard-looking. At his first visit there was a plug of hardened fæces stopping up the lumen of the stricture like a cork in the neck of a bottle. This being broken away, he was ordered confection of senna and quinine mixture, and would not hear of colotomy "at present." He still comes regularly, has improved in strength and appearance, and always says he is "wonderfully better"; but there is still the stricture. If he had been taking the turpentine I cannot doubt that it would have received all the credit for his improvement. Again, cicatrisation of a cancerous ulcer, such as has been going on in Case 10, though somewhat rare, is every now and again seen, more especially in old people and in cancer of the breast. During the last ten years I have seen eight or ten such cases at least, but the process is generally to be distinguished from healthy cicatrisation by the occurrence of fresh induration in or beyond the cicatrix, as in the above case. Lastly, one not unfrequently sees cases where the whole of a large tumour of the breast has sloughed away by degrees, leaving a narrow sulcus or fissure, with perhaps a small flattened indurated ulcer at one part, partly scabbed over, and having shallow sulci radiating from it into the thickened parts around. In some of these cases it is hard to believe at first that an operation has not previously been performed; but there has never been any reason to think that the tumour has "melted away" by the agency of any medicine.¹

It would have been a pleasant task to have reported a number of successes, and to have congratulated Professor Clay upon having made the discovery of a cure for cancer. But after a long and careful trial, the conclusion forced upon me is, that as a cure for cancer Chian turpentine is utterly valueless.

¹ These remarks are suggested by one or two of the cases which have been published in which Chian turpentine has been given.

PATHOLOGICAL SOCIETY OF DUBLIN.—The under-mentioned have been elected for the ensuing session:—President: A. Foot. Vice-Presidents: John T. Banks, Samuel Gordon, Edward Hamilton, Thomas Hayden, George H. Kidd, Joliffe Tufnell. Council: J. K. Barton, A. H. Corley, G. F. Duffey, J. M. Finny, R. J. Harvey, James Little, T. E. Little, R. McDonnell, William Moore, C. Nixon, J. M. Purser, W. Stokes. Secretary for Foreign Correspondence: J. W. Moore. Secretary and Treasurer: E. H. Bennett.

CLINICAL REMARKS TO STUDENTS ON THE DIAGNOSIS OF THE VARIOUS FORMS OF CONGENITAL HEART DISEASE.

By SEYMOUR J. SHARKEY, M.B.,
ASSISTANT-PHYSICIAN TO ST. THOMAS'S HOSPITAL.

(Concluded from page 847.)

THE diagnosis of the varieties of diseases of the heart acquired after birth has arrived at a perfection in no way attainable in cases of congenital disease. Indeed, it is, as a rule, impossible to say more than that a person has congenital heart disease, and to make a more or less probable suggestion as to its nature. Why this difference? you will ask. The principal points on which we rely for the diagnosis of ordinary acquired diseases of the heart are:—1. The fact that the blood passing through an orifice which is abnormally contracted, dilated, roughened, or guarded by incompetent valves, produces a murmur which is heard by the auscultator. 2. The murmur is heard in its maximum intensity in definite positions for each of the valves, and is conducted in the course of the stream of blood which produces it. 3. Observation of the time in the cardiac cycle at which the murmur occurs, which we express by the terms presystolic, systolic, and diastolic, helps to indicate the condition of the orifice at which the murmur is produced. 4. Those cavities of the heart which are behind the diseased part, that is, in the direction of the venous circulation, or which have any special stress thrown upon them, become hypertrophied and dilated, and we detect their increase in size by percussion.

Thus, for example, in aortic regurgitation: (1) a murmur is produced over the base of the heart, where the aortic orifice is situated; (2) it is diastolic in time and conducted down the sternum, that is to say, towards the left ventricle, into which the blood is regurgitating; (3) the left ventricle is found to be increased in size, owing to the additional pressure and work which is imposed upon it, by the blood which has already been propelled onwards ever returning to be propelled again.

Now in congenital disease there are at least two more orifices which have to be taken into consideration, in addition to those which are present in a normally formed adult heart. These are the aperture in the auricular septum and the aperture in the ventricular—orifices which are placed very close together and through which the blood may be flowing either from left to right or from right to left. There is likewise an additional vessel, the ductus arteriosus. Any one or all of these three structures may be opened or closed in any case without there being any means at our command for detecting their actual condition. Hence while in the adult we have an almost constant anatomical structure to deal with, in congenital diseases we have a variable one, and the varieties are not such as we can determine during life. When we try to apply to such patients the rules which serve so well for our guidance in cases of acquired disease, we soon see how lamentably they fail. Let us take an example or two.

If the case be one of constriction of the pulmonary artery there will also probably be present an aperture in one of the septa or a pervious ductus arteriosus, and the murmurs which may be produced as the blood passes through these structures will be added to that in the constricted artery, and will tend to confusion; or the murmur which should be occasioned at the diseased orifice may be suppressed, the pressure of the blood going through it being rendered insufficient for the production of an abnormal sound by the diversion of the stream in another direction. But more than this, we get little information, if we are not absolutely led astray, by observing the parts of the heart which are hypertrophied. If we conclude from an increase in size, which we find almost confined to the right side of the heart, that the pulmonary artery is the seat of disease, we may be right or we may be wrong. Should the obstruction to the onward flow of blood through the pulmonary artery be only partial, and should the septum ventriculorum be incomplete at its upper part and deviate, as it often does, to the left, so that the aorta rises partly from the right ventricle, then the latter

will be hypertrophied, owing to the obstruction in the pulmonary circulation which it tries to overcome, and to its efforts in assisting in the systemic circulation through the aorta. But suppose the obstruction is situated in the aorta, then the blood may flow backwards through the foetal orifices and be carried by the right ventricle into the ductus arteriosus, and so into the general circulation; and the right ventricle may become hypertrophied because it has to carry on not only the pulmonary but also the systemic circulation; while the left ventricle, which should have had the extra work to do, is relieved of its burden by the patent foetal openings, and may retain its natural size. Percussion then would indicate hypertrophy of the right side, whether the aorta or the pulmonary artery were the seat of the disease. Again, if the pulmonary artery were totally obliterated the blood would all pass over to the left side of the heart, and the left ventricle having to carry on the systemic circulation through the aorta and the pulmonary through the open ductus arteriosus, or other vessels, would become hypertrophied; while the right ventricle would be reduced in size, notwithstanding the presence of the abnormality on the right side. It is then the patency of these foetal communications which, while so beneficial to the patients, leads physicians all astray, by transferring the blood pressure, together with the hypertrophy which is caused by it, from one side of the heart to the other.

I venture to repeat, therefore, what I said before, that the most we can do in any given case is to diagnose the presence of congenital disease, and make a suggestion with more or less chance of being correct as to the exact seat of the abnormality. But, it may be objected, physicians do occasionally diagnose rightly the valvular lesion in congenital diseases. True, they do; but after all that is a very partial diagnosis, and of comparatively little worth. The value of a diagnosis must be gauged by its bearing on treatment and prognosis. The former is practically the same in all cases of congenital disease of the heart; but the prognosis should be very different according to the pathological condition present in each case. In acquired heart disease our prognosis depends—

1. On the particular lesion present, and our knowledge of the usual history of patients who are the subjects of it.

2. On the results of our physical examination of the heart, and the judgment we form as to the effect which the disease has already had on the muscular cavities which have to bear the brunt of it.

3. On the present general condition of the patient.

In congenital diseases of the heart, even if we detect the orifice which is the seat of the original disease, we are unable to make the really important part of the diagnosis: for we are unable to answer the question—what arrangements have been made in the course of development to neutralise the valvular defect by appropriate communications between the arterial and venous systems? Hence we are unable to say on what parts of the heart the stress has fallen, and how they have borne it. We have nothing, as a rule, to fall back upon but the general condition of the patient.

Let me conclude these few remarks by giving you the notes of two cases, which I had the opportunity of observing during life and of seeing examined after death—cases which illustrate well the points which I have insisted on. The patients were under the care of Dr. Peacock and Dr. Ord, to whose kindness I am indebted for permission to make use of them for my present purpose. A full account of Dr. Peacock's case may be found in the Transactions of the Pathological Society, 1878, page 43; of Dr. Ord's in the St. Thomas's Hospital Reports for 1879, page 227.

CASE 1.—E. P—, aged ten, was admitted under the care of Dr. Peacock on Nov. 28th, 1876. She had suffered from shortness of breath and pains in the chest from infancy, and was a puny, delicate-looking child. Her cheeks were flushed and her lips purple, and she had great dyspnoea on exertion. The feet were slightly oedematous, but the fingers were not clubbed or livid. The pulse was 108, somewhat irregular both in force and frequency; respiration short and rapid, 48. The chest-walls were very prominent over the cardiac area, and the dulness on percussion extended from the right nipple to a point just beyond the left, measuring in this transverse direction seven inches. A very loud musical murmur was heard all over the region of the heart, and was systolic and loudest at the base, though very evident at apex and faintly heard at the angle of the left scapula. The second sound was loud and crashing, especially on the left of the sternum. A thrill,

mainly systolic, was felt all over the heart, but was most distinct at the apex. The hepatic dulness descended to the level of the umbilicus, but the liver did not pulsate. The jugular veins were distended and pulsated. Respiration was puerile, but otherwise normal. Temperature 96.4°; urine 1031 sp. gr., and contained no albumen. The patient suffered from pain and paroxysms of dyspnoea at intervals. By Feb. 7th, 1877, the dropsy had increased, and the urine contained a quantity of albumen. She had much pain and severe paroxysms of dyspnoea, and there was much bronchitic rhonchus in the chest. She died on Feb. 24th, and during the latter part of her life the cardiac murmur was heard most loudly at the apex.

On post-mortem examination it was found that the heart was enormous. The right auricle and ventricle were greatly dilated and occupied almost the whole anterior aspect of the heart. The pulmonary artery was greatly dilated, but the valves healthy. The aortic and mitral valves were healthy, but the aortic orifice was very small, as was the whole thoracic portion of the vessel. In the auricular septum was a large orifice, which measured 3.4 inches in circumference. The foramen ovale and ductus arteriosus were closed.

The probable history of this case is, I think, that during intra-uterine life the development of the aorta was owing to some cause or another arrested. This increased the blood-pressure abnormally behind the aortic orifice, so that the blood found a way of escape into the right auricle through the incomplete auricular septum, and kept open a permanent orifice in it. The right side of the heart being thus constantly over-filled, acted with greater energy; and, by constantly propelling more than the normal amount of blood into the pulmonary circulation, it not only greatly increased in size itself, but also caused a simultaneous increase in the size of the pulmonary artery.

The closure of the foramen ovale, notwithstanding the persistence of an aperture in the auricular septum, may probably be explained by the fact that the blood flowed from the left to the right auricle, and, as the valve of the foramen ovale projects on the left of the septum, the increased blood-pressure in the left auricle would tend to close rather than to keep it open. When we consider the physical signs during life—viz., great increase of cardiac dulness to the right of the sternum, and but slight increase to the left, a thrill most evident at the apex, and a murmur which, though heard everywhere, was at first loudest at the base and subsequently at the apex—we must confess that no one could have solved the problem and predicted the results of the post-mortem examination.

CASE 2.—M. A. J.—, aged thirty-four, was admitted under Dr. Ord on Oct. 29th, 1879. She had had measles, but no other severe illness; had always suffered from palpitation, some shortness of breath, and tendency to blueness on exertion, but she had nevertheless worked hard. She had also suffered from occasional epileptic fits for the last twelve months before admission. When seventeen years of age she was "blown up" in a cartridge factory, when her spine was injured and her right leg broken. Her illness, for which she was admitted into St. Thomas's Hospital, commenced three weeks previously with pain in the "stomach," unaccompanied by tenderness or vomiting. On Oct. 29th she had been walking quick to get to the hospital in time, when she vomited a large quantity of blood. On admission the patient was ill-nourished, anæmic, short of breath, and altogether very ill. There was evident pulsation in the jugular veins. The cardiac area was prominent, and pulsation could be seen from the second intercostal space on the left to a point two inches below and within the nipple. A thrill could also be felt all over the cardiac area, but was most marked over the origin of the pulmonary artery. Dulness on percussion extended upwards to the first intercostal space on the left, to the right as far as mid-sternum, and to the left just beyond the nipple. A loud, crashing, systolic murmur could be heard all over the heart, but was most intense at the base, being heard loudly up the sternum and towards the left clavicle, and much less so to the right of the sternum. The lungs were resonant. She died on Nov. 7th.

Post-mortem examination.—The abdominal viscera were transposed. The pericardium measured seven inches and a half vertically, seven inches transversely in the line of the nipple. A number of old, white, thickened patches, from half an inch to an inch in diameter, were situated on the visceral layer of the pericardium on the anterior surface of

the right ventricle, and on the front of the great vessels at the base, where in some places they projected in conical villous masses. The heart was very large, and the greater part of it was situated on the left of the median line. Its anterior surface was almost entirely formed by the right ventricle. The right auricle and ventricle were greatly dilated and hypertrophied. The left auricle was also very much enlarged. The left ventricle was comparatively small. The conus arteriosus and the pulmonary artery were enormous, and apparently gave rise to the great increase of dulness to the left of the sternum towards the clavicle, which was observed during life. Though the calibre of the pulmonary artery was so greatly increased, the vessel and its valves were healthy. The septum ventriculorum was complete, and the ductus arteriosus closed. The auricular septum was very thin, and the foramen ovale was altogether open and destitute of valve. But, besides this, the whole of the lower part of the septum was absent, so that a very free communication existed between the two auricles. The tricuspid valve was healthy, and on looking up from the right ventricle towards the auricles, one saw clearly into both of them, the defect in the auricular septum being in a direct line between the left auricle and right ventricle. The mitral valve was thick, and the orifice constricted, not admitting two fingers. The aortic valves and orifice were healthy, though the vessel was rather small.

The probable history of this case is that the mitral orifice becoming diseased the flow of blood through it was obstructed, and the stream became diverted through the incomplete auricular septum, which consequently remained undeveloped. The blood arriving in the right auricle, as well as part of that in the left, was propelled through the tricuspid orifice into the right ventricle, and the latter became greatly hypertrophied owing to the abnormal amount of work thrown upon it. The great quantity of blood driven into the pulmonary artery by the hypertrophied right ventricle gave rise to an increase in the size of this vessel, while the small quantity of blood which passed through the aorta was accompanied by a diminution in its calibre.

It is possible, however, that an abnormally largely developed pulmonary artery was the original malformation, and that the incomplete septum, the diversion of the blood from its natural course, and consequent diminution in the size of the mitral orifice and aorta, were only secondary results. But whatever may have been the true intra-uterine history of the case, the only thing which could have been diagnosed during life was an abnormal condition of the pulmonary artery; while neither the condition of the auricular septum nor the mitral valve could have been determined. Such a case brings forcibly before us how little skill we can pretend to in the diagnosis of congenital diseases of the heart, and justifies, I think, some of the remarks which I have made upon this subject.

ON A CASE OF EXCISION OF THE SCAPULA.

By EDWARD BELLAMY, F.R.C.S.,

SURGEON TO CHARING-CROSS HOSPITAL; HON. FELLOW OF KING'S COLLEGE, LONDON.

ALTHOUGH the operation of removal of the entire scapula has been performed on several occasions, the cases are sufficiently uncommon to warrant an isolated one being placed on record, and that in detail, with any remarks which may have the effect of adding to the celerity of its execution and its bloodlessness. The proceeding has been instanced as "conservatism" in its highest sense, yet it is quite open to question whether, when undertaken for obvious malignancy, the term is absolutely applicable; however, there is no doubt that, if it be supposed that the scapula only be involved, it is the surgeon's duty to undertake it.

The patient on whom I recently performed this operation was a strong healthy-looking boy, fourteen years of age. A small swelling was observed about the middle of the scapula in August last, and when seen by me he was supposed to be suffering from a dislocation of the humerus; it was, however, evident that it was a very rapidly increasing malignant growth, probably either encephaloid or a round-celled sarcoma, forcing the humerus away from the

scapula. The tumour, when I operated, was about as large as a child's head, non-adherent to the integument, and the scapula was freely movable over the structures normally in relation with it.

On account of its rapid development I decided to remove the entire scapula at once, but I particularly desired to preserve the clavicle and humerus, as the scapulo-humeral articulation was evidently uninvolved. Accordingly, on Oct. 2nd, I operated as follows:—With the view of preventing hæmorrhage, I first cut down upon the subclavian artery, and directed an assistant to compress this vessel against the first rib, and to be ready to grasp the first flap should the bleeding be very severe. Next, I directed a second assistant to extend the arm forward with one hand, and to compress the axillary artery as high up in the axilla as he could with the other, in order to control the subscapular artery, which in this instance was easily detected, as it was thrown up by the growth. I thus prevented any large amount of blood from passing into the arm, and calculated on arresting any return current by the second manœuvre. My first incision extended from the tip of the acromion to the base of the spinous process, and the second along the spinal border of the scapula, involving integument only. I then nipped through the acromion. The tissues gaped sufficiently to expose the entire mass, which bulged into the wound. Next, I divided the muscular attachments to the spinal border, and passing my knife beneath the separated acromion, disarticulated the humerus. Grasping the mass with my left hand, I dragged it downwards and outwards towards the axilla, and divided the muscular attachments to the upper border of the bone, having now the tumour entirely under control. I now swept the knife along the axillary border, and the scapula and its growth were removed. The cutting part of the operation occupied but a few minutes; strict antiseptic precautions were adopted, and the wound healed by first intention. In a few days, unfortunately, the site of the acromion showed signs of recurrence, and accordingly on Oct. 28th I proceeded to remove it. I found that the disease was progressing downwards past the apex of the axilla, and evidently infiltrating all the tissues. Any further operation I regard as useless mutilation. My scapular excision was an attempt at conservatism, and in the face of a round-celled sarcoma an attempt merely.

The main points I desire to call attention to are the bloodlessness of the operation and the ease of removal of the mass. I have had the experience at present of but one case in my own practice, but I have seen others, and have been struck with the apparent difficulty of the operation. Of course, there may have been greater complications; but it would seem to me that by getting well under the scapula from its spinal border, and tilting it outwards and downwards towards the axilla, a large amount of leverage is obtained, and disarticulation may be performed with great rapidity, a factor of importance when hæmorrhage is expected.

The lad has complete control over the arm and forearm, and the divided scapular muscles seem already to have acquired some kind of attachment.

If I ever have the occasion of removing the scapula for a "growth" again, I shall take care to avoid any attempt at the preservation of the symmetry of the shoulders, supposed to be gained by leaving the acromion, and excise the bone *in toto* to the scapulo-clavicular articulation, on the chance of the disease being confined to the bone itself. Further, I should certainly not undertake it in the event of *immobility* of the scapula, or any decided failure in its "excursion" over the ribs.

Wimpole-street, Cavendish-square.

NOTE ON HEMIN, OR SO-CALLED HYDROCHLORATE OF HEMATIN.

By J. L. W. THUDICHUM, M.D., F.R.C.P. LOND.

On page 116 of the "Physiological Chemistry," by Dr. Gamgee, occurs the following statement:—"It is held by Thudichum that hæmin contains no chlorine, and he therefore looks upon it as crystallised hæmatin."

In the journal of the Chemical Society for September, 1876, will be found a paper by myself and my then assist-

ant, Mr. C. T. Kingzett, entitled "On Hemin, Hematin, and a Phosphorised Substance contained in Blood-corpuscles." In the research embodied in this paper the following was proved. Hemin, prepared by one of us, by a modification of Wittich's process (Eleventh Report of the Medical Officer of the Privy Council, 1869, p. 155), entirely crystallised in very minute bluish-black rhombic plates was analysed and found to contain 7.651 per cent. of iron, 3.021 per cent. of chlorine, and 0.608 per cent. of phosphorus (mean of three analyses). We then say: Hemin has been considered as a hydrochloride of hematin; by others, again, as a basic hydrochloride, or mixture of hydrochloride of hematin with free hematin. Our researches show that it contains besides these two bodies a considerable amount of a crystallised phosphorised substance. It is thus proved that the crystallised state of substances of such high atomic weight as the body before us is no guarantee of chemical purity or definite composition.

We then describe experiments intended to saturate the hemin with hydrochloric acid. Of this 3.3 per cent. were added to the hemin. This experiment shows that crystallised hemin is by no means saturated with hydrochloric acid, but contains hematin in the uncombined state; this latter probably takes up some of the hydrochloric acid added. But the possibility that the myelin (phosphorised substance) contained also in the hemin may also take up some hydrochloric acid cannot be lost sight of, and is raised to a probability by the known bearing of myelin from brain matter. In the next division, treating of the action of nitric acid upon hemin, we disprove a statement of Preyer, made in the little pamphlet on blood-crystals, so copiously used by Gamgee, that he had found suboxide of iron (ferrous oxide) in a solution containing excess of nitric acid. In the fourth division we show that hemin, subjected to treatment with concentrated sulphuric acid, yielded cruentin, the body first described by one of us in the Report of the Medical Officer of the Privy Council for 1867 (p. 228) and 1868 (p. 161). The fact that this body (cruentin), with many salts and varieties, was first discovered at the time, and first described in the publication mentioned, is not stated by Dr. Gamgee, who describes it as the discovery of a continental chemist, although the observations of the latter were not published until four years after those just quoted. We then proceed in the fifth division to describe experiments intended to effect the extraction of iron from the hemin by the process of C. Paquelin and L. Jolly,¹ and get as a result (after extraction and isolation of the phosphorised body) a hematin in which the iron had not only not been diminished, but which contained more iron than had ever before been found in any preparation of hematin. Its analysis led to the formula $C_{32}H_{32}FeN_4O_6$. We then disprove a statement of Hoppe-Seyler, who had explained an inconvenient excess of nitrogen found by him in his analyses of hematin as due to an absorption of ammonia from the air, by showing that mere vestiges of ammonia make hematin soluble in water.

In the last division of the paper we describe the isolation, properties, and analyses of the phosphorised body, and its cadmic chloride compound, and show that it is an amidated myelin, almost identical in composition with an amidated myelin isolated by one of us from the brain. This is the first and only analysis of the phosphorised body from blood-corpuscles ever made. It is not given in Dr. Gamgee's text-book.

On page 114 of his treatise Dr. Gamgee says that hemin, which he terms hydrochlorate of hematin, can be transformed into hematin by solution in potash and neutralisation of this solution by hydrochloric acid. The washings are to be tested with solution of silver nitrate. At the conclusion of the paragraph he quotes Hoppe-Seyler as his authority, and at the foot of the page the place, "Beiträge zur Kenntniss des Blutes des Menschen und der Wirbelthiere. Das Hæmatin. Med. Chem. Untersuchungen," Heft iv., 1871, s. 523.

Now, in that publication, and at that place, Hoppe-Seyler prescribes that the dissolved hemin shall be precipitated with sulphuric acid, and shall be washed with water (not "boiling water," as Gamgee says) until barium chloride leaves the washings clear.

Earl's Court-road.

CONGENITAL COLOUR-BLINDNESS INCURABLE.

By Dr. B. JOY JEFFRIES.

IN an English medical publication for August 21st is an editorial notice of Dr. Favre's paper read before the Paris Academy of Medicine on the "Relations of Colour-blindness." Dr. Favre's mistaken belief in the curability of congenital colour-blindness is apparently agreed with from this sentence: "All these circumstances go to prove that such an examination should be more generally resorted to, and that the colour-blind should be made responsible to the law for their mistakes; and as Daltonism can for the most part be cured by exercise, the legislation required would certainly become an excellent therapeutic agent. Those persons who were past cure would be warned that they must abstain from giving any judgment on coloured objects."

It seems particularly unfortunate that editorial credence should be given to Dr. Favre's ideas just at a time when a very general testimony of the members of the British Medical Association has drawn the attention of the profession to the subject of colour-blindness. It should at least have been stated that he stands almost alone in this belief of the curability of congenital colour-blindness by exercise with colours. A few years ago Dr. Favre's mistake might have been very natural, but at the present time, after the careful reports of the examination of many colour-blind by the best scientific observers, who have also worked practically, a belief in it should no longer be indulged. It is a most dangerous error to promulgate among the laity that a colour-blind sailor or railway employé can be cured by exercise with colours.

I took ground against Dr. Favre on this point in the *Boston Medical and Surgical Journal*, March 28th, 1878, quoting especially Nilson and Holmgren in my support. I have since then devoted a chapter to the subject in my volume on "Colour-blindness: its Dangers and Detection." I will not lengthen this communication by quoting from my book, as all can there read what is said. Since my book went to press a number of very competent observers have criticised Dr. Favre's curious mistake and shown the fallacy of his reasoning. This is especially the case with those gentlemen who have had time and opportunity to study the colour-blind and patiently test in many ways their chromatic sense, as Donders, Holmgren, Magnus, Cohn, Stilling, Pflüger, Netoliczka, Fontenoy, and others.

Respect for authority and isolation in my early work, alone prevented me from sometimes doubting whether the colour-blind could not see differently after years of familiarity with colours. I have since then come in contact with colour-blind scientists, chemists for instance, who have done everything to try to improve by practice their chromatic sense, and I have by intercourse with and watching under examination more than seven hundred colour-blind, learned somewhat more of how they supplement their defect, both by their other senses and, so to speak, through their very defect, as has been lately explained by Professor J. Stilling in his monograph on the "Vision of the Colour-blind."

Dr. Favre induced his teacher friends to test their scholars for colour-blindness by asking them the names of coloured objects. The girls could tell, the boys could not. Hence from 10 to 30 per cent. of the latter were called colour-blind, and these were cured by teaching them the names of the colours. This absurdity is now self-evident. Upon it was based his belief in the curability of congenital colour-blindness. He may not now adhere to the whole of what he once recorded, but his aim is the same.

The laity who see how the colour-blind who have had practice with colours will get on and conceal their defect, particularly if these laity are officially or pecuniarily interested in preventing legislative control of this dangerous defect, cannot often and will not even disbelieve in the change of the colour sense. The importance, therefore, of constantly impressing on the community that the chromatic sense does not alter, and as far as possible explaining the natural deception, must be recognised by all. Dr. Favre's opinion in this matter has no weight in Europe, as his per-

haps natural mistake has been often pointed out most satisfactorily. The editorial endorsement of it in the medical publication before referred to might, however, give it temporarily some weight in England, till such criticism as has been passed in Europe, and as I have here made, disabuses the community, the medical at least, of the value of the recorded observations.

I have thus called attention again to this important point, as the effort for control of colour-blindness and visual defects on land and sea is being pressed in all parts of the civilised world, and an International Commission has been proposed to discuss and agree on standards of efficiency and standard tests, a Bill having been reported and introduced into the last session of the American Congress, authorising the United States Government to take the initiatory steps for the formation of this commission.

Boston, U.S.A.

CASE OF CANCER OF THE UTERUS DURING PREGNANCY.

SAFE DELIVERY TO MOTHER AND CHILD.

By JAMES TURNBULL, M.B., C.M. EDIN.

Mrs. P—, aged forty-one, consulted me on February 28th, 1879. She complained of great weakness and loss of appetite. She had no particular pain, but stated that for the last three or four months the menstrual flow had become more frequent and lasted longer than formerly. This she attributed to the change of life, and objected to a vaginal examination. She was a little woman with an anæmic and unhealthy-looking appearance. She had five children, the youngest five years old; all her labours but the first had been easy. On examination I could detect no heart, lung, or renal disease. I prescribed a mixture of perchloride of iron and solution of the extract of ergot to be taken thrice daily along with nourishing food and wine. Under this treatment she improved considerably in health and appearance. On May 13th I was sent for as she had an alarming attack of hæmorrhage. I found her in bed, looking pale and exhausted. Her pulse was very rapid and feeble. She had evidently lost a large quantity of blood. On examination I found the vagina filled with dark clots of fetid odour. Growing from the posterior lip of the os I felt a nodulated mass of friable structure, which bled freely on being touched. The growth had a broad surface and was attached by a broad pedicle to the posterior lip of the os. I cleared the vagina of clots and swabbed the surface of the growth with a saturated solution of perchloride of iron in glycerine. This had the effect of completely staying the hæmorrhage. Hitherto my attention had been chiefly directed to the uterus per vaginam, but on passing my hand over the abdomen I could feel it enlarged, though not to any great extent. I suggested to her the possibility of her being pregnant. She said she had not the slightest idea of such a thing, more especially as she had menstruated so recently, and she had none of the feelings she used to have in the early months of her pregnancies. Evidently she had mistaken the hæmorrhage from the growth for menstruation. My diagnosis was cauliflower excrescence with probably coexisting pregnancy.

Of the nature of the tumour there was no doubt, as I examined a portion of it under the microscope and found it to be epithelial cancer.

The pregnancy was not sufficiently far advanced to make the diagnosis absolutely certain. I therefore determined to wait rather than pursue investigations further at that time. In about a week or so afterwards the difficulty was removed beyond a doubt, as the patient felt the movements of the child, and the fetal heart could be heard beating distinctly. The hæmorrhage did not return, and she continued to improve in general health.

On Saturday, Oct. 19th, at 10 A.M., I was sent for, as labour had commenced. There had been a considerable amount of hæmorrhage. The vagina was filled with clots. The os was sufficiently dilated to admit the introduction of the tip of the forefinger. The growth did not seem to have increased much in size, and appeared to be entirely confined to the posterior portion of the cervix uteri. The head was presenting, the membranes were intact, and the child was alive. The pains came on at long intervals, and

were not very strong. Labour went on slowly during the next four days; the patient's strength kept up wonderfully. On Wednesday, at 1 P.M., the pains became more severe, and were attended by gushes of blood. To stop the hæmorrhage, which was excessive, I introduced into the partially dilated os a piece of sponge saturated in perchloride of iron in glycerine. This had the desired effect. The os would then admit two fingers. About 9.30 P.M. she began to get restless, and seemed much exhausted; her pulse rose to 120, her temperature to 99° 6'. The membranes were ruptured and the pains had entirely ceased. I determined, therefore, to deliver at once by means of the long forceps.

The difficult conditions to overcome were two—viz., a rigid undilatable os and the obstruction of the diseased mass to the passage of the child. Owing to the disease being confined to the posterior lip of the os, I was able to dilate the anterior lip with my fingers, though only to a slight extent. The head was above the brim, with the anterior fontanelle to the right. Having administered chloroform I applied Barnes' long double-curved forceps. After pulling steadily at intervals I felt the head begin to advance, and in half an hour from the application of the forceps the patient was delivered of a fine healthy male child. A large portion of the diseased structure came away in front of the head. The placenta separated easily, and there was no further hæmorrhage. For two hours after delivery she was much exhausted, but on the administration of a little brandy and sedative solution of opium she soon rallied. For several days after delivery her temperature continued high, but otherwise she had no bad symptom. On the eighth day her temperature became normal; on the sixteenth day she was able to be out of bed. For the next three months she was able to attend to her household duties, and seemed in good health, having no pain or discharge. At the end of February of this year the disease began to spread rapidly, involving the bladder and rectum in its course. Having read of Mr. Clay's wonderful success with Chian turpentine in the treatment of this disease, I at once adopted his method, but am sorry to say without success. Possibly the disease was too far advanced before beginning the treatment. My patient sank under the disease May 23rd, 1880.

Such cases are fortunately rare in practice, and no definite rules for their treatment can be given. The duration of the labour was extremely long. Having read of such cases terminating favourably when left alone, I resolved to give nature every possible chance. I think, however, the condition of my patient was such as to warrant immediate interference, as she was rapidly sinking. I can hardly venture to say that it was good practice to draw the head through a rigid partially dilated os. I did so with the hope that if laceration did take place it would be through the cancerous mass. I cannot tell what actually did take place, not caring to explore too much, and being only too glad to bring such a long and anxious case to so favourable a termination.

LONDON HOSPITAL.

OVARIAN DYSMENORRHOEA, WITH RETROFLEXION OF THE UTERUS; SYMPTOMS DEMONSTRATED TO BE UNCONNECTED WITH THE RETROFLEXION.

(Under the care of Dr. HERMAN.)

In this interesting case, for the notes of which we are indebted to Mr. Winskell, it was demonstrated that the symptoms present were not connected with retroflexion of the uterus.

S. B—, aged twenty-three, a servant, single, attended the obstetric out-patient department on Nov. 28th, 1877. She stated that she had had rheumatic fever when aged eight, and the usual infantile disorders, but otherwise her

health had been good till her present illness. She first menstruated at fifteen, but was never regular, the flow returning at intervals varying from two to four weeks, frequently being brought on by fright or excitement. The hæmorrhage usually lasted five days, and was copious. Since the age of sixteen it had been accompanied with pain, which had gradually got worse, and for the last two or three years it had been so severe as to lay her up. The pain was wont to come on from two days to a week before the flow, and to reach its height on the third day of the hæmorrhage. It was described as a dull, heavy pain, constant, not paroxysmal, relieved by lying down; situate about two inches internal to each anterior superior iliac spine, in the sacral region, and extending down the thighs. The pain was worse when the flow of blood was profuse. For two or three years the pain had been felt not only at the menstrual periods, but in the interval as well, though less severely. For twelve months she had been troubled with leucorrhœa, and much pruritus of the vulva. Too frequent micturition was the only other local trouble. For two years her appetite had been bad; the bowels were habitually constipated, and there was also a feeling of weight and fullness after food. Sleep was disturbed, and the patient was very nervous; this was attributed to a fright four years ago.

On examination there was found tenderness on abdominal pressure over the situation of either ovary. Per vaginam, the uterus was found to be movable, natural in size, so sharply retroflexed that the body seemed to form with the cervix a right if not an acute angle. It was easily reducible with the sound, but fell back again directly the instrument was removed. Much pain was caused by pressure on the body of the uterus. Per rectum there was greater tenderness on each side of the uterus, the most being on the left side.

She was treated as an out-patient until May 18th, 1878. Medicines were given to improve digestion and general health, and various kinds of vaginal pessaries (Hodge's and its modifications) were tried, but none could be got to keep the uterus in the axis of the pelvic brim. There was no improvement in the symptoms, which, if altered at all, got rather worse.

On May 18th, 1878, she was admitted into the hospital. She had begun to menstruate on May 14th.

On the 30th, Wynn Williams's intra-uterine stem and shield were put in. She was subsequently examined several times at intervals, in order to ensure the pessary being kept in its proper position.

On June 17th the stem was still resting in the socket of the shield intended to receive it, so that from May 30th to June 17th the uterine canal was perfectly straight. She menstruated from June 6th to the 15th with *more pain than usual*. She felt only slightly, if at all, better in her general condition than when admitted. During the last few days she had complained of a discharge slightly mixed with blood, and of much pruritus. As, therefore, the mechanical straightening of the womb did not seem productive of benefit, the stem and shield were removed, and a thick india-rubber ring (the so-called "watch-spring" pessary) was put in. After the introduction of the ring the uterus was found bent back, the body resting on the ring, but the flexion not so acute as when the patient was without a pessary.

The patient menstruated from July 1st to the 8th less copiously than usual, and with "no pain to speak of." On the 12th she had no pain at all. The leucorrhœal discharge was better; the pruritus had been relieved by the use of calomel ointment. The uterus was in the same position as when the last note was made. The patient, who had kept her bed since admission, was allowed to get up.

On July 27th the uterus remained in the same position; patient thought herself quite well, and was sent to the country.

It will be seen from the foregoing that while straightening the uterus did not relieve the patient, the symptoms disappeared under the influence of rest, while the retroflexion was still present.

On November 16th the patient stated that she had thought herself perfectly well till the 13th, when she lifted something heavy, and fancied the effort had done her some harm; but she could describe no definite symptom. She was still wearing the ring, but the uterus was now in the axis of the pelvic inlet, not retroflexed, as formerly.

On Nov. 30th, the uterus being still in the normal position, the ring was removed.

On Dec. 14th she complained that her old pains were re-

turning. The uterus was still straight, and in the axis of the pelvic brim, although the patient had been for a fortnight without any pessary.

It is not needful to describe in detail the further progress of the case. It will be enough to state that her old symptoms gradually returned; that after they had persisted many weeks, the womb again became retroflexed. As she did not improve under treatment as an out-patient, she was not encouraged to continue attendance; and finally, in April, 1879, the flexion being presumably still present (nothing further having been done to correct it), the patient became pregnant.

Remarks by Dr. HERMAN.—Many gynaecologists hold that flexion of the uterus is a morbid condition which gives rise to symptoms; among others, to dysmenorrhœa and sterility. It is beyond question that flexion of the uterus frequently exists without any symptoms whatever. Where, as in this case, bending of the womb is found associated with symptoms, the causal relationship of the flexion to the symptoms is generally only a matter of hypothesis. The only way in which the hypothesis can be tested is by the effect of treatment; symptoms caused by bending of the womb should of course be removed when the uterus is straightened, and return if the organ should again become bent. It is not in every case that the treatment can be carried out in such a manner as to completely test this point, and cases recorded in which it has been thus demonstrated that the flexion is harmless are few. One case, of course, does not settle so wide a question; but as the one just reported is an item of singularly clear evidence, I have thought it worth record. The main facts of the case are these: (1) That the stem, which kept the uterus quite straight, did not relieve the symptoms. (2) That the symptoms disappeared while the flexion was still present. Did these facts stand alone, it might be asserted that the irritation necessarily caused by an intra-uterine stem prevented the relief brought about by the removal of the flexion from being as manifest and as speedy as it would have been had the uterus been straightened by less severe means. The next fact in the history of the case disposes of this view; for (3) the symptoms returned, although the flexion was absent. These three facts seem to furnish complete demonstration that the flexion had nothing to do with the symptoms. There are some other points, of less importance, which the case illustrates. (4) The case shows the least injurious effect of intra-uterine stem pessaries—viz., pain, discharge, and slight hæmorrhage; symptoms evidently due to traumatic endometritis, and which so commonly follow the use of these instruments, that one authority who recommends them has stated that he looks upon hæmorrhage and free discharge as good signs. (5) Although the uterus was retroflexed, the patient became pregnant. This fact would never have been ascertained had not the patient previously suffered from symptoms leading to an examination of the pelvic organs. It is obvious that no one can tell how many healthy young women there may be in whom the uterus is retroflexed, but who suffer from no symptoms, and when married quickly become pregnant. But until this is known it cannot be proved that flexion of the uterus causes sterility. This case is an item of evidence against the theory which assumes that it does. There is, of course, no ground for asserting that what took place in this case will also happen in others; but it may do so, and perhaps oftener than is supposed.

NEWCASTLE-UPON-TYNE INFIRMARY.

CASE OF CEREBELLAR TUMOUR; NECROPSY.

(Under the care of Dr. PHILIPSON.)

FOR the following notes we are indebted to Mr. E. L. Prowde, M.A., clinical clerk.

A. U—, aged thirty-four, a bricklayer, was admitted March 25th, 1880. He stated that he had enjoyed good health up to October, 1878, when he began to suffer from attacks of violent headache, giddiness, and vomiting. Subsequently he noticed that he could not see distinctly, and that he could not hear with the left ear. About this time he was told by his friends that his face was twisted. He admitted that he had lived very freely, and that he had suffered from syphilis when twenty-five years old.

At the time of his admission his expression was vacant. His face was drawn to the right side. He was unable to close the right eye, to wrinkle the right side of the brow, and

to whistle. His tongue when protruded was directed to the right. His food lodged between the teeth and cheek of the left side. There was no anaesthesia. When placed with his heels together, and with his eyes closed, he had a tendency to fall backwards. His gait was reeling, resembling that of a drunken person. The pupils were moderately dilated, equal, and, upon ophthalmoscopic examination, marked double optic neuritis was observed. The respiratory, circulatory, and genito-urinary systems were normal. His bowels were constipated. His principal complaint was of severe occipital headache, paroxysmal, vomiting, and slight difficulty in swallowing.

The diagnosis, as entered by Dr. Philipson, was that of a cerebellar tumour, gummatous in nature. Such was founded upon the following symptoms:—The persistent headache, the continuous vomiting, the paralysis of certain of the cranial nerves, the reeling gait, and the syphilitic history.

He was prescribed the iodide of potassium in large doses three times each day, the bromide of potassium at night, and a saline purge from time to time in the morning. Under this treatment the severity of the headache was somewhat relieved, but the vomiting continued, and, during May, convulsions occurred, tonic in character.

On July 26th it was noted that he was quite unable to walk, from a tendency to reel from the right to the left; on August 7th, that he was giddy when propped up in bed; and on August 14th, that he was rolling about in bed, and that he was delirious. On August 27th he was attacked with severe and persistent hiccough, which continued up to his death, which occurred on August 28th.

Autopsy.—On removing the brain it was found that the cerebellum, on the left side, was adherent to the portion of bone corresponding to the left internal auditory foramen, which foramen was large and excavated, and capable of admitting the end of the index-finger. The bone was eroded. This abnormal adhesion was found to be due to a tumour in the region of the left lobe of the cerebellum. The tumour was about the size of an ordinary jargonelle pear, elliptical in shape, soft, consistent, resembling brain matter, although of a yellow colour on section. The pons was very much flattened on the left side. The rest of the brain was normal. The tumour, upon microscopical examination, was found to resemble granulation tissue, in the general character and arrangement of the cellular structure.

MISSION HOSPITAL, KASHMIR.

OBSTRUCTION OF THE BOWELS CAUSED BY LARGE WORMS; AMUSSAT'S OPERATION; DEATH.

(Under the care of Dr. E. DOWNES.)

A MAN, about forty years old, applied at the out-patient room in June, 1879, complaining of constipation. Purgatives were administered and repeated. After a day or two his case became so serious that he was admitted. Purgatives and belladonna and enemata were tried without effect. On the second day he suffered considerably. There had been absolutely no evacuation for some days. There was vomiting, and it seemed that unless something was soon done he would die of the obstruction. There was no sign of a hernia. Enemata were tried once more, but to no avail. Towards evening it was resolved to perform Amussat's operation that night as a last chance of saving his life if there was not a speedy evacuation.

At about 9 P.M., accompanied by Dr. Ross, the civil surgeon, Dr. Downes saw the patient, and found him in the same state, or, if anything, weaker, and suffering more pain than before. There had been no evacuation. Without further delay he was placed under chloroform. The abdomen was a little tympanitic in places, and absolutely dull in others. It was very much distended, and some coils of intestines could be seen and felt pretty plainly through the abdominal walls distended with fluid faeces. The colon could not be made out. After a brief consultation, it was agreed to perform Amussat's operation.

An incision four inches long was made about two inches above the crest of the ilium on the left side, and about parallel to it. It was made with the greatest care. The structures were divided one by one on a director. At last, what was believed to be the colon was reached. This turned out to be a mistake, for on passing a silk suture into it to draw it forward, fluid escaped having a faecal smell; but it

evidently was not the bowel, but the peritoneal cavity. On opening it carefully a considerable amount of fluid escaped, and portions of two coils of intestine were seen much inflamed, and so distended with fluid and so compressed against one another that it was difficult to recognise them. One had a transverse direction, and it was taken to be small intestine; the other, which was behind and hidden by the former to some extent, appeared to pass downwards. With the opinion that this might be the descending colon, a portion (about an inch) was taken up in two places, about an inch apart, with a curved needle threaded with silk. The gut was gently pulled forward by the two threads, and the superficial portion divided with a bistoury to the extent of an inch; a tremendous gush of liquid fæces was the consequence, and the stench was so abominable that it was with difficulty that the operation could be completed. The middle of the two threads was pushed up and divided, and then the gut was pulled to the two margins of the external incision and fastened to the skin. All this time the patient was rolled on his left side, and care taken to prevent the fæces from entering the peritoneal cavity. An immense amount of fæces was expelled, and the wound was cleaned and closed with sutures, leaving the artificial anus.

The operation took nearly an hour, and the patient's pulse was weak, and the surface of the body cold. He was put to bed, and was ordered to be kept warm; some brandy was given, and simple, nourishing food, such as milk and soup, was ordered. Next morning he was comfortable, free from pain, and took his food fairly well; fæces had passed by the rectum, and none had that morning come by the artificial anus. Already the gut had become adherent to the margins of the wound; the sutures were therefore removed, and the wound dressed with lint and carbolic oil.

On the morning of the third day he was not so comfortable, and fæces were passing both by the artificial anus and the rectum. The patient's mother stated that an immense number of round worms had passed by the wound; she said about two pounds of these worms had been thus passed. A large round worm was seen finding its way out, and there seemed no doubt the obstruction had been caused by these worms. The bowel, which was rather protruding from the wound, looked inflamed, and there was a good deal of pain in the bowel, near the artificial anus. He was weaker than on the previous day, and the appetite was gone.

On the morning of the fourth day he was still weaker, and some blood was discharged by the artificial anus. At his request he went home, and he died shortly after reaching his home.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Hydro-encephalocele.—*Varicocele with small Testicles.*—*Ulceration of the Colon, with Hypertrophy and Dilation.*—*Right Hemiplegia after Scarlatina.*

The ordinary meeting of the Clinical Society was held on Friday, Nov. 26th, the President, Dr. Greenhow, in the chair. The papers read bore on subjects of considerable interest, but excited little discussion. Three living examples of skin diseases were also shown—erythema iris, lichen scrophulosorum, by Dr. Radcliffe Crocker; and tubercles in association with factitious urticaria, by Mr. Marrant Baker.

Dr. CARRINGTON read a paper on a case of Hydro-encephalocele, which he had exhibited last session. The boy, aged seven, an inmate of the Chelsea Infirmary, was under the care of Mr. Fortescue Ingram. The child was born by means of instruments; nothing was noticed wrong until he was two years old, when the back of the head began to protrude, and slowly increased, but has remained stationary for several months past, if not longer. At the upper and back part of the cranium is a large tumour, measuring fourteen inches and a half in circumference at its base, and seven inches and a half over its vertex from side to side. It is completely sessile, with a broad base, soft and fluctuating, non-pulsatile, not translucent. Compression

produces no effect at all, and the boy can stand on his head without any ill result. The tumour apparently springs from a large deficiency in the cranium, involving the parietals, especially the left, along the sagittal suture, and the posterior part of the left side of the frontal bone. There is a moderate amount of talipes varus. His general health is good; intellectually he is sharp and cunning, always cheerful, and keeps up an incessant prattle, which, however, is rational. When three years old he was knocked down by a cab, and since then has suffered from fits, which are usually short and transitory, but attended with complete unconsciousness; these have become more frequent and of longer duration during the last seven months, two having lasted some hours. There is weakness, with slight wasting, of the right arm and leg, also increased lately, and a peculiar mode of moving the arm, resembling that of athetosis. There is no optic neuritis. The boy has developed a lateral curvature of the spine, the left shoulder projecting more than the right.—Mr. MARSH asked whether any treatment had been employed, and whether it was not justifiable to tap the tumour with one of Southey's fine trocars; cases are on record where such treatment has resulted in cure.—Dr. CARRINGTON replied that the only treatment up to the present time had been the administration of bromide of potassium, which had exerted some control over the fits. He thought that to tap the tumour would be quite reasonable.

Mr. PEARCE GOULD showed two cases of Varicocele with small Testicles, and read a paper on some points in the pathology of this disease. One of the men shown was eighteen years old; the varicocele was large, had been noticed five months, but gave rise to no symptoms. The testicle was about half the size of the right, but of normal shape and consistence, with slightly exaggerated testicular sense. There had not been any previous injury or disease of the part; no other varices. The other man was seventeen years of age, presenting an almost precisely similar condition, the testicle being even smaller than in the first case; here the scrotal swelling had been noticed seven years, and had not altered during that time. After quoting the views of Paget and Curling as evidence of the prevailing uncertainty as to the effects of varicocele upon the nutrition and function of the testicle, Mr. Gould pointed out that in many so-called examples of atrophy of the testicle from varicocele there was a history of previous injury to, or inflammation of, the part; and he insisted that all such cases must be carefully excluded in an inquiry into this point. In many other cases no mention is made of the history, and they must therefore be accepted with caution. With these reservations he grouped cases of so-called atrophy of the testicle from varicocele in three series: (1) Cases in which the varicocele interfered with the full development of the gland at puberty, and in this group he placed the cases exhibited; (2) cases of very slight atrophy of the gland, a condition difficult to determine with certainty, but believed to be common; he had seen examples of it; (3) cases of extreme wasting of the testis. Though there is reason to believe in the occurrence of this atrophy, he had never seen an example of it, and did not know of any recorded case where the history was so precise as to exclude the possibility of its being either an undeveloped organ, or wasted as a result of injury or inflammation. That varicocele may cause sterility he considered proved by Curling and Gosselin: After the radical cure of the varicocele, slightly wasted or undeveloped testicles attain their normal size. Mr. Gould maintained that neither the greater length of the left spermatic vein, nor its passage beneath the sigmoid flexure, nor its mode of entrance into the renal vein, satisfactorily explained the relatively great frequency of varicocele on the left side; he suggested that the use of the valve usually present at the mouth of the left spermatic vein was to convert the direct aperture of the vein into an oblique one, and that the passage of the blood along the renal vein exerted an aspirating effect upon that in the spermatic vein; in one case he had observed where the valve was absent, the vein entered the renal vein obliquely. In comparing varicocele with other varices, it was shown that it is a disease of early life, most often arising before or at puberty; that it may remain stationary for years and not cause any symptoms, or may undergo spontaneous cure; that the veins are not subject to thinning of their walls and spontaneous rupture, and that it is not produced by the common causes of other varices; and it was thence argued that varicocele was not produced by a

yielding of the veins to increased internal pressure, but was a true venous hypertrophy. And Mr. Gould suggested that the special tendency to the development of venous tissue at this spot, evidenced in the normal pampiniform plexus, was re-excited at puberty and led to an abnormal development, either concurrently with or at the expense of the growth of the testicle. He maintained that there are cases of varicose veins of the lower extremities of the same kind—venous hypertrophies. Mr. Gould intends to practise the operation he recently described in our columns for the radical cure of the cases shown. A case in which this was performed with success thirteen months ago was shown to the Society, as was also a case of varicocele of several years' duration, stationary, and without any injurious effect on the testicle.—Mr. BRYANT thought that facts bore out Mr. Gould's theories. The affection is one of early puberty. He had seen a most typical instance in a boy of seven, in whom there was nothing to suggest a mechanical cause, and since that case he had met with three or four others in boys under puberty, and all of these had been on the left side. Some of the worst cases he had ever seen had been on the right side, and, although it was common on both sides, he could clearly recall two cases in which it was on the right side only. The cause of varicocele is certainly obscure, but the mechanical theory may be discarded. He also agreed with the view expressed in the paper that there is no evidence to show that the small testicles sometimes met with are really atrophied, and he was disposed rather to accept the theory of their being undeveloped. There is no doubt that where the radical cure has been performed, such organs grow and attain their proper size. He mentioned a case of a gentleman who had a large and very troublesome varicocele, with small testicle, on whom he operated, and eighteen months after the testicle was as large as the right, having formerly been only half that size. This patient married soon after the operation. Such cases are strong arguments for operating for varicocele, though it was only certain cases of varicocele that required it. He mentioned two cases of hæmatocele, which had followed violence or strain. In one the tumour was very large, and was mistaken for a hernia, and the surgeon's efforts for its reduction ruptured one of the veins; the other was ruptured during coughing.—Mr. WALSHAM had found in nearly all cases a valve two inches from the opening of the left spermatic vein, and he thought this an objection to Mr. Gould's view of the use of the valve at the mouth of the vein.—Mr. GOULD thought that in such cases as Mr. Walsham alluded to the vein was double almost up to its end, and that this valve merely acted to turn the blood into the alternative channel. He was at a loss to understand how the valve at the orifice of the vein could assist the circulation, if not in the way he had indicated. Mr. Bryant's cases confirmed his statements, and particularly that hæmatocele only results from injury to varicocele; never spontaneously.

Dr. GOODHART read notes of a case of Ulceration of the Colon, with Hypertrophy and Dilatation, in a girl of seventeen. The patient was admitted into Guy's Hospital, under Dr. Goodhart's care, on August 25th, 1880. She had always had delicate health, and in December, 1879, this began to fail, but without any definite symptoms. Her abdomen had been gradually increasing in size since January of the present year, but more rapidly in the last month. She had never had any severe pain in the abdomen, but had suffered from slight sudden pain at times. Since the onset of the abdominal swelling in January, the bowels had been irregular; sometimes she had had constipation, at others diarrhœa. In the last three weeks the bowels had acted seven or eight times a day, the motions being offensive and blackish in colour, with inability to retain them. The action of the bowels had caused no pain. She was remarkably anæmic and spare, and seemed very ill. Her pulse was 128, and her abdomen very much distended. The distension was found to be due to large, hard masses in the abdomen, which disappeared and reappeared in various parts, and were obviously due to a forcible peristaltic action on the part of the bowels. The peristalsis was, indeed, visible; and the abdomen was everywhere resonant. The abdomen was not tender. It contained no fluid, and there was no evidence of enlargement either of liver or spleen. She was suffering from a rather profuse diarrhœa, the motions being dark-coloured, quite liquid and offensive, but she confessed to little pain at any time, and none when the bowels acted. Her temperature was 100°. The other viscera were all healthy. The diagnosis rested upon her age, the extreme pallor, and evident severe illness,

the abdominal distension with increased peristalsis and frequent diarrhœa—all these symptoms slowly increasing in the course of eight months; and few will probably be found to criticise the opinion that the patient was suffering from *tabes mesenterica*; that the disease of the mesenteric glands had led to shortening of the mesentery; and this to intestinal obstruction of a partial kind, from which, and from the ulceration which would in all probability exist under such circumstances, the frequent diarrhœa resulted. The case was somewhat like that of a child who had been partially under Dr. Goodhart's care some months before, suffering from *tabes*, and in whom a fistula formed at the umbilicus, by which the obstruction was relieved; and the opinion was hazarded that from the distended appearance of the umbilicus perhaps a similar occurrence might happen in this case, but she was so ill that it seemed hardly likely that she would live long under any circumstances. The diagnosis seemed to be so clear that no other alternative one was suggested, and there was nothing in the progress of the case during the few remaining days of life to advance any suspicions as to its correctness. *Liquor bismuthi* and liquid extract of Bael were ordered, and the diarrhœa checked, but by no means arrested. The temperature varied between 99° and 101·6°; her pulse between 120 and 136. Death came by way of a sudden attack of abdominal pain, followed by speedy collapse, for which no remedies proved effectual. The inspection was made by Dr. Horrocks. The abdomen was enormously distended and tympanitic, the lower part of the colon being greatly dilated and occupying the entire front of the cavity. The sigmoid flexure occupied the right iliac fossa, having pushed the cæcum, which was not enlarged, backwards and inwards. Drawing the bowel from the ileum along the ascending colon, it was found that the latter suddenly dilated about the hepatic flexure, below which point it became wider and wider, so that the rectum formed a huge cylinder of seventeen inches in circumference. The dilated part contained a large quantity of black pulaceous fecal matter, without scybala, and some of this was exuding into the peritoneum from a small perforation in the sigmoid flexure. The dilated colon was much thickened and tough. It contained several ulcers—two close to the anus, immediately inside the external sphincter, oval in shape, and the size of half a crown, each of them. A little higher up were two others, and in the sigmoid flexure was a large one, with sinuous margins, in the middle of which was a small slough, with a central perforation. In all the ulcers the mucous membrane was destroyed, leaving the muscular fibre exposed, the surfaces being smooth, and the edges thick. There was no stricture at any part. The pelvic viscera were healthy. The following circumferential measurements were made after the bowel had been laid open:—Cæcum 7½ in.; hepatic flexure 11 in.; sigmoid 13 in.; rectum 17 in.; ileum 3½ in. The symptoms in this case were undoubtedly those of *tabes mesenterica*, but it is to be noted that the hypertrophied bowel produced when contracting masses of such hardness as were noticed at the time to be very unusual, and it may well be doubted whether, under such conditions of obstruction as were assumed to be in existence, *tabes mesenterica* ever leads to such a condition of hypertrophy of the muscular coat of the bowel as existed in this case. The remarkable absence of pain is another feature which ought, perhaps, to have led to a reconsideration of the diagnosis. The relations existing between the hypertrophy, dilatation, and ulceration were next discussed; and it was remarked that if the history of the case were discarded, undoubtedly the most probable explanation of the case is that from some unknown cause ulceration of the rectum had occurred, that this had led to spasm of the sphincter, and so to obstruction. But this hypothesis could not be so easily accepted—1st, because the history was very much against it; 2nd, because ulceration of the colon is a not uncommon result of distension; and 3rdly, because ulceration of the rectum is very uncommon in girls of this age. And it was suggested that the anæmia and ill-health of the patient made the general features of the case not unlike those of a few cases on record where dilatation of the stomach has occurred in young people without the existence of any obstruction at the pylorus,—cases which are paralytic rather than obstructive. It was then, in the light of this view, attempted to be shown that hypertrophy of muscle might follow partial paralytic distension, from what is known of the relations between hypertrophy and dilatation in other parts; and finally, the author combated the view that this was simply a case of hysterical

constipation, and entered shortly on the question of the effects of treatment in such cases.

Dr. HORROCKS made the autopsy of this case; the cause of death was evidently the perforation of the bowel, but he could not find any cause for the hypertrophy of the bowel, and he thought it must have been set up by ulceration of the bowel and then spasm during defecation. He could not agree with Dr. Goodhart that it followed atonic dilatation. There was no straining in defecation, and no scybala were found after death.—Mr. BRYANT considered that the hypertrophy of the colon must have been due to chronic obstruction of the bowel of some kind or other; the ulceration was secondary and similar to that seen particularly in the cæcum in cases of organic obstruction. He had had in Guy's Hospital a man, aged twenty-seven, who had been operated on when a child for imperforate rectum, but latterly had neglected himself and suffered from more permanent obstruction and died. At the post-mortem they found enormous dilatation and hypertrophy of the cæcum, colon, and sigmoid flexure, and the intestine ulcerated and gangrenous in parts. That it may occur in hysteria he was sure, and he instanced a case of an hysterical girl, aged twenty-four, on whom right lumbar colotomy had been performed for a supposed organic stricture; he closed the fæcal fistula, and several times passed his hand into the colon, which was quite flaccid and loose. After injections and other treatment it recovered its tone and she was cured. He thought this case was analogous to Dr. Goodhart's.—The PRESIDENT remarked that he had never seen such a condition; and he asked if in Mr. Bryant's male case the distension and hypertrophy were as great as in Dr. Goodhart's.—Mr. BRYANT replied that they were as great, if not greater.—Dr. GREEN thought the case very obscure. He had never seen visible peristalsis in *tabes mesenterica*, and should rather expect to find the intestines paralysed in that condition. He also doubted whether chronic constipation due to loss of power could be followed by hypertrophy of the gut: the two conditions were so opposite.—Dr. GOODHART had seen visible peristalsis in one case only of *tabes mesenterica*. There was no proof of hypertrophy of the colon in Mr. Bryant's second case, and he thought that was the difference between hysterical and this paralytic dilatation; the one is not and the other is followed by hypertrophy. Dilatation and hypertrophy of the heart go on *pari passu* if the primary dilatation is not excessive. In cases of stricture of the bowel scybala are never found in the intestine above the obstruction, for the constant churning movements of the bowel erode the scybalous masses.

Dr. F. TAYLOR read a case of Right Hemiplegia after Scarlatina, with embolism of the middle cerebral artery, destruction of Broca's convolution without aphasia, and death from diphtheria. The patient was a boy aged five years, and was seized, two weeks after an attack of scarlatina, with hemiplegia of the right side. There was no aphasia, but the boy answered questions intelligently and in long connected sentences. There was sensation in the leg, but not at first in the arm, and there were occasional attacks apparently of the nature of convulsions. Two or three weeks later sloughs occurred on the back of the hand and fingers; later still the right arm and leg became œdematous, and the urine was subsequently found to be albuminous. About nine weeks after the onset of the illness he was attacked with nasal and pharyngeal diphtheria, of which he died in a few days. At the post-mortem examination there was found embolism of the left middle cerebral artery, with extensive softening of the left hemisphere, involving the posterior portions of the second and third frontal convolutions, the lower parts of the ascending frontal and parietal, the supra-marginal convolution, the island of Reil, the corpus striatum, and the anterior part of the inner capsule. The heart showed a few minute vegetations on the mitral valve; it was not dilated. The right kidney had two large embolic infarcts, and the right hand presented over the abductor indicis one large, irregular ulcer, the result of sloughing of the skin, and three small sloughs on the fingers. Dr. Taylor called attention to the frequent occurrence of cerebral hemiplegia in connexion with exanthems in children; in many instances no opportunity was afforded of demonstrating the exact manner in which the paralysis was brought about. Thrombosis of the cerebral vessels was regarded as a frequent cause; but the present case showed that obstruction of the vessels might also arise from embolism as a result of an acute cardiac disorder. In relation to the persistence of the faculty of speech, it appeared from the history that the child had been left-handed, in consequence

of some enfeebled condition of the right arm, which was noticed from birth. This places the case in the category of those which seem to show that the speech centre is located on that side of the brain which is most educated for muscular movements. A third point of interest was the occurrence of diphtheria; its late appearance renders it probable that it was independent of the previous infection by scarlatina.—Dr. MAHOMED remarked that many cases of hemiplegia after the exanthemata are to be explained by the dilatation of the heart, with or without valvular disease, that frequently follows those diseases. He had recently observed cases of marked dilatation of the heart after scarlet fever. In a case of diphtheria that died from a dilated heart, he found thrombosis of the auricles and embolisms in many parts of the body, but not in the brain.—Dr. ALTHAUS thought the pathology of cases of hemiplegia after exanthemata obscure, but thrombosis and embolism were the most common cause. The destruction of Broca's convolution without aphasia was very interesting, but it was an apparent exception that really proved the rule.—The PRESIDENT regarded Dr. Taylor's case as very special, and quite different from the paralysis so common after diphtheria and typhoid fever. He had seen a good many cases of diphtheria occurring at an interval after scarlet fever; most of them were fatal.—Dr. TAYLOR replied that there was no evidence of dilatation of the heart at the autopsy; the signs of endocarditis were distinct, though slight. He did not bring forward this case as illustrating the sole cause of hemiplegia after exanthemata, but only one special form. It was an important question how exanthemata brought about the changes in the heart.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Perforation of Stomach in Hydrochloric-acid Poisoning.—Cerebral Embolism.—The Treatment of Genu Valgum.

At the meeting on the 29th ult., F. J. Gant, Esq., President, in the chair—

Dr. GILBERT SMITH exhibited a specimen of Perforation of the Stomach due to Poisoning by Hydrochloric Acid. The patient was a boy, aged six years and a half, who had swallowed about a tablespoonful of spirits of salts on the morning of admission into the London Hospital. Intense pain in mouth and throat was immediately followed by vomiting of dark-red matter. The vomited matters subsequently became colourless mucus, streaked with brownish material. There was much secretion from the mouth and fauces, deglutition was impeded, and there was great difficulty in breathing, especially in inspiration. There was much collapse, and death took place seventeen hours after taking the poison. The post-mortem examination revealed but little change in the buccal mucous membrane; that of larynx and trachea was red; the œsophagus of an ashy-grey colour; the mucous membrane of the stomach was red, except close to the pyloric end, where it was black, and in parts digested away; a perforation was found at the greater curvature, and there was recent peritonitis. The case was a typical one of poisoning by this acid, in which perforation occurred in about one-third of the cases. Death generally took place within twenty-four hours; in one case it occurred in so short a time as two hours; and to a girl, aged fifteen, one drachm had proved fatal. The laryngeal symptoms were due to the irritation set up by the volatile properties of the acid.

Dr. DOUGLAS POWELL showed a specimen of Endocarditis which had been attended with Multiple Embolism. The case illustrated the fact that embolism of both middle cerebral arteries might take place without any definite symptoms marking the event.—Dr. SYMES THOMPSON referred to a case of advanced heart disease, where the patient was attacked by aphasia on two separate occasions; the first lasted less than a day, the second occurred six months after, and continued for several days. Death took place from pyæmia, but was preceded by embolism of the posterior tibial artery.—Dr. DOWSE questioned whether the infarcts were not due to thrombosis, owing to a general inflammatory condition of

arteries in these cases.—Dr. D. POWELL said that in most of the cases there was no evidence of a general arteritis.

Mr. S. BENTON exhibited a boy, aged thirteen, who had made a good recovery from severe Knock-knee, being treated simply by tenotomy and instrumental means. Before treatment there was a divergence of 15 inches between the internal malleoli, and he could not walk without great pain and difficulty. One year ago he was admitted into the North-West London Hospital, and was three months under treatment. Mr. Benton divided subcutaneously the biceps tendon of both legs, and on the left leg he also divided the external lateral ligament. The instrument devised by Mr. Henry Baker was employed. The legs are now straight, the joints are quite strong, there is no stiffness or impaired movement, and the boy can walk eight or nine miles without fatigue. Great stress was laid on the selection of a suitable instrument, and the need of personal supervision in the treatment.

Mr. RICHARD DAVY then read a paper on the Advantages of Ogston's Operation in the Treatment of Genu Valgum. He thought the present opportunity a good one for upholding this operation, as so much had lately been published on the respective value of splints, tenotomy, and osteotomy. He could not admit any superiority in "extra-articular" osteotomy (as described by Mr. Reeves), and narrated his own case of excision of the inner condyle of the femur in 1871 for confirmed genu valgum, as a proof that surgical attention had been directed towards that point. The joint was opened without antiseptic precautions; the boy made a good recovery, and can now walk ten miles a day. He warmly praised Ogston's ingenuity in suggesting the oblique division of the inner condyle by a valvular opening. The cases suitable for the operation were the confirmed cases, where the horizontal plane of the condyloid end of the femur is markedly at fault, and progression interfered with by brushing of the knees. The rationale of the operation and the manner in which the obliquity of the condyle is increased were described and illustrated. He strongly urged the importance of an early diagnosis, as in that way cutting operation might be anticipated. He then described the method of operating, and exhibited a knife with a groove in one side of its back for the introduction of Rose's saw. The after-treatment was simple, but it was necessary to re-educate the patient on a fresh balance. The results were complete, and he had never seen a fatal case. He summarised Ogston's cases in Aberdeen, and also recapitulated ten cases of his own—eight left knees, two right knees. Constitutional errors and general treatment must not be lost sight of, and no surgeon could be so specially interested in any one operation as to overlook the characteristics of rickets, and indiscriminately perform it; but the fully confirmed rickety habit should not forbid the operation. He summarised its advantages as follows:—1. It is an operation mechanically correcting a mechanical defect. 2. Its conduct is simple, safe, and satisfactory. 3. No special antiseptic precautions are needed. 4. Its good results are rapidly gained; the tendency towards aggravation of the deformity is lessened. 5. There is but a trivial risk to the patient, and the operative impression seems to be permanent. 6. All future instrumentation at the hands of the surgical mechanician is abolished. Mr. Davy showed a boy, aged fourteen, who had been operated on ten months and a half previously. His height had increased three inches; his malleoli touched (there had been a divergence of sixteen inches and a half), and he could walk eight miles a day. The operation is a grand resource in these protracted cases of genu valgum, and the fact that two knee-joints had been opened in the same patient at one sitting and the condyles sawn off is a striking example of the progress of modern surgery.—The PRESIDENT said the author had not laid sufficient stress upon the risks of the operation in relation to the after-condition of the joint and the life of the patient.—Mr. HENRY BAKER said that Mr. Benton's case was a severe one, and the result excellent; the strength of the joints showed that fears as to permanent weakness following tenotomy and division of the external lateral ligament were unfounded. He asked Mr. Davy what were the dangers of division of the biceps tendon, which he had said was as dangerous as Ogston's operation.—Mr. EDMUND OWEN regretted that the two cases exhibited had not derived their improvement—he could not term it *cure*—from splinting alone, in spite of its tediousness. He found flat-foot and genu valgum so frequently associated that he looked upon them in the light of cause and effect; but he attributed the immediate cause of the joint deformity to a giving way of the internal lateral

ligament of the knee on account of its deriving little or no support from the adjoining fibrous structures; the internal lateral ligament had as allies the tendon of the biceps and the ilio-tibial band of fascia. Tenotomy had been spoken of as a trivial operation, and Mr. Davy urged that osteotomy even without Listerian precautions was less serious still; but no cutting operation should be lightly spoken of. He wished to know the ages of the patients on whom Mr. Davy had operated, as some surgeons had operated on children of two, three, and four years.—Mr. PEARCE GOULD called attention to Dr. Macewen's measurements in cases of genu valgum; he had found that the most frequent deformity was a curving inwards of the lower third of the femur or a lengthening of the inner side of the femur. The inner condyle is elongated in 84 per cent. of cases, but often to only a very slight extent. This was the explanation of the failure of Ogston's operation. Even in Mr. Davy's case there was an interval of five inches between the malleoli when the patellæ are placed directly forwards. In his experience he had never seen a severe case of genu valgum really cured by this operation. Mr. Barker had had a fatal case, and Mr. Gould had had a fatal case after osteotomy of the tibia. He had also seen suppurative of the joint, and stiffness; whilst Dr. Ogston himself mentions two out of eight cases with stiffness for months, and thickening round the joint. Dr. Macewen's operation was quite free from those dangers, and he believed it would soon completely replace Ogston's where osteotomy was necessary. No operation was perfectly safe; and certainly osteotomy could not be performed so perfectly subcutaneously as tenotomy.—Mr. ROYES BELL considered the case treated by instrumental means was most successful, but that it was not such a severe case of rickets as Mr. Davy's. Genu valgum was, no doubt, often associated with flat-foot, but the cases shown were very slightly affected; and many cases of flat-foot did not suffer from knock-knee. The osteotomies done at King's College Hospital were performed antiseptically.—Mr. WALSHAM could not agree that Ogston's operation was so safe as Mr. Davy avowed. He had seen a considerable number of patients treated by this method; and although many cases had been quite as successful as those of Mr. Davy, still he had seen very grave results follow—such as synovitis, suppurative of the knee, and one fatal case. Macewen's operation was the one now generally performed at St. Bartholomew's Hospital, and the one he most preferred.—Mr. DAVY, in reply, said five years and upwards was about the age of his cases, and pointed out the advantages as to time and convenience of operation compared with mechanical contrivances. He thought Ogston's would be the operation of the future.

Reviews and Notices of Books.

Demonstrations in Physiological and Pathological Chemistry.

By CHARLES HENRY RALFE, M.A., M.D. Cantab.
London: David Bogue. 1880.

The subject treated in this book is one which we venture to say hardly receives sufficient attention in the medical schools. Whilst the incomplete character of the preliminary examinations of most of the licensing bodies compels the schools to undertake instruction in the very rudiments of inorganic chemistry, the pass examinations do not require any more than a very superficial knowledge of the chemistry of the animal body. This, it must be confessed, is a weak point in the present curriculum; for although certificates of attendance upon classes of practical physiology are enforced, the examinations mostly do not *practically* test the knowledge of the candidates, except, perhaps, in the department of histology, which is not physiological but anatomical knowledge. On the other hand, it is by no means uncommon for candidates to be well posted in the more intricate problems of physiology gained from theoretical study, and at the same time to be profoundly ignorant of even elementary facts in physiological chemistry. There can be no question as to the importance of the subject in its bearings upon practical medicine; and for this reason, if for no other, we regard the publication of this book as most timely, and think that

it will be found of great use as a laboratory guide on the subjects of which it treats.

The author tells us that the book is based upon the systematic instruction he has for some years given at St. George's Hospital, and he has arranged the subject in the form of demonstrations. The first of these may be taken as a type of the whole. It deals with the saccharine and amylaceous principles. After their enumeration and general characters starch is dealt with separately, and all its reactions given; then follows glycogen, a brief physiological statement preceding the description of its method of preparation and its characters; next comes glucose, and, finally, lactose and inosite, which are treated in the same systematic way. The chapter concludes with a list of the materials, reagents, and apparatus necessary for the demonstration. The same methodical plan pervades each demonstration, the second chapter dealing with the fatty principles, and the third with the albuminous. Under the head of "Products of Decomposition," a chapter is devoted to the properties of lactic acid, and the long series of substances derived from the splitting up of the albuminoid bodies—viz., xanthin, cystin, kreatin, leucin, tyrosin, hippuric acid, uric acid, and urea. In the fifth demonstration the subject of digestion is discussed, and the properties of the digestive fluids detailed in order. The next two demonstrations deal with the nutritive fluids (blood, milk, chyle, and lymph) and the solid tissues (muscle, nerve, and bone). The demonstration that follows is upon the urine, and is an excellent account, within a small compass, of the physiological and pathological conditions of this excretion. A classification of the causes and conditions under which the colour of the urine is altered is useful, and there is a full disquisition upon the causes in the fluctuations of the reaction of the fluid. The conditions under which variations in the urinary constituents occur are then pointed out, and the characters of urinary deposits—freely illustrated—are described. The abnormal products met with in morbid urine follow next, and we note in passing that as a test for blood Dr. Ralfe regards the "guaiacum test" as very unreliable, since globulin, casein, mucin, &c., will develop the blue reaction when blood is absent. We miss any detailed reference to indican, although it is mentioned under the head of colour, but it is found in so many conditions that its importance may be overrated. Analysis of urinary calculi concludes this section. A chapter upon quantitative analysis and the manner of carrying this out in the gravimetric and volumetric methods concludes the book.

Dr. Ralfe has succeeded in producing a book which should be very useful not only to the student but to the teacher, and to those practitioners who are able to devote their leisure to the study of an attractive and important subject. By following strictly in the lines sketched out by the author, the student will find himself possessed of a sound knowledge of animal chemistry in health and in disease.

The Atomic Theory. By AD. WURTZ, Membre de l'Institut, Doyen honoraire de la Faculté de Médecine, Professeur à la Faculté des Sciences de Paris. Translated by E. CLEMINSHAW, M.A., F.C.S., F.I.C., Assistant Master at Sherborne School. London: C. Kegan Paul & Co. 1880. (International Scientific Series.)

THE fame of this excellent scientific series will not be impaired by the present, its thirtieth volume. The publishers have been wise in their choice of a book, and particularly fortunate in their translator. Mr. Clevinshaw has performed his task with equal care and skill. The translation is accurate and yet smooth, French idioms are almost entirely absent, French scientific phrases are well rendered, and there are, on the whole, very few misprints. Of the latter we notice the following as having some importance,

and as being easily corrected: Page 96, line 19, ethylene oxide should be ethylene; page 159, the atomic volume of gallium should be 11.7 instead of 1.17; page 202, line 3, for C_2H_6 read C_3H_8 ; page 253, the formula for potassium platinichloride is printed wrongly (probably the French author's error); page 257, line 20, for $VOCl$ read $VOCl_2$; page 321, line 19, "hundredths of millionths" should have been "millionths." Some errors of this kind are, of course, unavoidable in a first edition.

In the book itself there is much to praise and a little to lament. The modern chemical theory, in the establishment of which M. Wurtz has helped so materially, is expounded with remarkable clearness and brilliancy and with extensive learning. The historical order has been adopted, and the growth of our knowledge of chemical composition, reaction, and constitution, and of the physical laws with which they are inseparably connected, is traced side by side with the growth of the atomic and molecular hypotheses by which the results of experiments have been explained and the experiments themselves in many cases suggested. The earlier chapters of the book are almost entirely satisfactory, and everyone with the most elementary knowledge of chemistry will read with pleasure and profit the story of the successive discoveries and theories of Proust, Richter, Lavoisier, Dalton, Gay-Lussac, Avogadro, Berzelius, Dulong and Petit, Mitcherlich, Gerhardt, Dumas, Cannizzaro, Williamson, Frankland, Wurtz, Kopp, Kekulé, Kolbe, and Mendelejeff, to quote only a few from the long and illustrious roll. We are glad to note that but little national bias is perceptible in the history, and although it is annoying to find the law of gaseous elasticity uniformly ascribed to Mariotte, who did not, instead of to Boyle, who did, discover it, we must remember that Mendelejeff, a Russian chemist, gets the whole credit of the periodic law to which Newlands, an English chemist, was the first to draw attention.

We have said that the earlier chapters are almost entirely satisfactory. Their chief defect lies in this, that the author throughout uses too much the tone of an advocate anxious to make the best of his case, and therefore apt to slur over the difficulties, many or few, which beset it. This tendency is more apparent in the later chapters, and we cannot help thinking that better service would have been rendered to science if the stumbling-blocks in regard to the theory of atomicity had been more fairly recognised. That the theory is in the main useful, and within certain limits probable, no one doubts; but that it is capable of giving a satisfactory explanation of all the facts of mineral chemistry is by no means so certain, and we are inclined to think that it breaks down altogether in regard to some. The combination of hydrochloric acid with ammonia, involving apparently the fixation of chlorine to nitrogen, the existence of double salts containing the chlorides of monad metals, and numerous other cases that might be quoted, cannot at present be explained, and the fact should be fairly admitted.

The later chapters contain a very interesting sketch of modern views and discoveries in regard to the constitution of matter, in which the ideas of Van't Hof and Le Bel, Clausius, Clerk Maxwell, and, above all, Sir W. Thomson, are indicated. A fuller exposition of these hypotheses would be very useful just now.

The Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D. Third Edition. London: Smith and Elder.

THE appreciation of this work by the profession is shown by the call for a third edition within so short a period of its first publication. In the present issue several important additions have been made, which bring the work up to the present state of obstetric practice. We find in it a full account of

the Cæsarean section, with the modifications proposed by Porro, where, in addition to opening the uterus and the removal of the foetus, the ovaries and uterus are also extirpated. A chapter is devoted to Laparo-elytrotomy, an operation proposed to take the place of the Cæsarean section, in which the advantages of the former over the latter operation, and the cases for which it is suitable, are clearly and ably set forth. In the chapter on Transfusion the observations of Schäfer, recently published, have been incorporated. The work has been carefully revised, and maintains its high position as one of the best text-books on midwifery.

New Inventions.

THE AROMATIC AND DEODORISING WATER-CLOSET.

THIS closet, the property of Messrs. Brazier and Son, 106, Blackfriars-road, presents some novel points. It is composed entirely of earthenware, and is in two pieces, the basin and the trap. The basin is of the ordinary conical form, with a flushing-rim. The trap into which it fits is an ordinary S bend, with a ventilating shaft leaving its highest point. The novelty consists of a subsidiary chamber, forming one piece with the trap, and communicating with it below the water-level by a small hole. There is a special plug-hole for "charging" this subsidiary chamber. The charging consists in putting some quicklime in the bottom and attaching a bag of camphor to the margin of the plug-hole. The water is then allowed to flow into the subsidiary chamber, and the level of the water is the same as in the trap. The plug is then replaced, and the only interchange between the trap and the chamber is by diffusion, for it is evident that no flow can take place from the chamber (in which the fluid is retained by atmospheric pressure as in a "bird fountain") into the trap. The chamber contains water saturated with camphor and lime, and if the water in the trap be not renewed too often that also becomes saturated with camphor and lime.

What the effect of a watery solution of camphor and lime may be upon sewer-gas or faecal matter we must leave professed chemists to determine and practical men to find out after a fair trial of this novel invention, the name of which is strangely contradictory, for that which is aromatic cannot be without odour.

MEDICAL TRIALS.

EXCHEQUER DIVISION.

(Sittings at Nisi Prius, before MR. JUSTICE STEPHEN and a Common Jury.)

EATON v. BASKER AND OTHERS, COMMITTEEMEN, AND THE MAYOR, CORPORATION, ETC., OF GRANTHAM.

MR. DAY, Q.C., and Mr. Finlay were counsel for the plaintiff; Mr. J. C. Lawrance, Q.C., and Mr. Dugdale appeared for the defendants.

This was an action brought by a surgeon against two sets of defendants to recover £97 7s. 9d. for medical attendance supplied to the poor in certain fever tents at Spittlegate and Little Gonesby, near Grantham, during an epidemic of scarlet fever in July, August, and September, 1878. The defendants pleaded that this was not a contract under seal; that if it was a contract it was contrary to sec. 200 of the Public Health Act, 1875; and that the contract was not made by the Local Board of Spittlegate or Little Gonesby, or by the Corporation under their seal. But these defences were stigmatised by Mr. Day in his opening as the reverse of meritorious; and he laid stress on the fact that this was a

very special attendance, as the fever tents were in a field, to isolate the patients, distant some one and a half miles from Grantham, where Mr. Eaton resided. It cut the plaintiff practically off from the rest of his practice, as few people would like to employ a doctor brought into such painful contact with a raging scourge as the fever then was, being of a particularly malignant type. While thus employed, the business of the plaintiff was almost wholly suspended. After arguments by counsel on either side as to the law of the case, Mr. Justice Stephen said he should allow the case to proceed, and the plaintiff was called, and deposed that Dr. Ashby, the medical officer of the sanitary authority, had applied to him to undertake the fever tents after a meeting in the Town-hall. At first he declined, as he believed it would injure his practice; but Dr. Ashby insisted that some one must do it, and the plaintiff suggested the names of several other well-known practitioners in Grantham. Whereupon the doctor replied they had most of them large and young families, and they much objected to running that risk; that the plaintiff must undertake the work, as he was the only bachelor in the profession in the town. Upon this the plaintiff consented, stipulating for half a guinea per day for the first two tents of six patients, and 5s. 3d. a day for every other similar tent. At first there was overcrowding, for Dr. Ashby had sent seventeen patients to the tents that properly held twelve. The witness had attended from June 30th to September 15th, sometimes seven hours a day, sometimes five or six, sometimes less; coming generally three times a day one and a half miles out of town. Out of sixty-five patients treated there only six had died. A correspondence was then read between the plaintiff and the secretary of the defendants, from which it appeared they had offered him at different times £58 and seven guineas, which sums, it was said, Dr. Ashby would pay after application and notice. The plaintiff added in his opinion his claim was a great deal too low.

Mr. Lawrance thereupon said he could not, on the part of the Mayor and Corporation, go on contesting the amount, some £30; but he submitted the committee were not personally liable, and the Corporation could not be sued on a contract not under seal.

Ultimately it was agreed to discharge the jury, and reserve these points of law for further consideration before his Lordship.

INFECTIVE PHTHISIS.

To the Editor of THE LANCET.

SIR,—The following, making due allowance for the ignorance and terminology of the period, looks so like a case in point, that if you do not think my estimate of it overstrained I will thank you to publish it in THE LANCET. It occurs under the head of "Catching an Atrophy," in Fizerbert's "Life of Cardinal Allen," and was taken by me from a little brochure, entitled "Cardinal Allen's Defence of Sir William Stanley's Surrender of Deventer," Chetham Society's publications, p. 69. The italics are mine, and the context implies, I think, that syphilis was not the cause of this "infection." However that may be, acute tuberculosis, or so-called galloping consumption, would appear to me to be the more appropriate interpretation; and I will only add, that I never saw or heard in India of the precautions against phthisis that Dr. Thompson mentions. "In those days [the reign of Elizabeth] a certain noble English youth, who had been entrusted to Alan's care at Louvain, had an atrophy, *his body gradually growing thinner*. As Alan, *assiduous in doing his duty*, remained with his pupil, he was also in a short time *infected with the same wasting away*, unnoticed at the commencement, for he was a man of vigour, *and yet the disease was not slight, as presently appeared*; for the poison was so attracted to the marrow, and so infused into the viscera, that besides infecting Alan with a disease which no course of time would cure, it so set at defiance all medicine, *that it threatened to bring him to a speedy death*, unless some escape . . . might by chance be obtained from the goodness of his own native climate and soil. Therefore Alan . . . returned stealthily to England," and regained in time his former health, as we learn from other sources.

Your obedient servant,

WILLIAM CURRAN.

Warrington, Nov. 1880

THE LANCET.

LONDON: SATURDAY, DECEMBER 4, 1880.

WE are threatened with another epidemic extension of small-pox in the metropolis. The disease is becoming very active in the eastern districts, and it has already overpassed the hospital accommodation provided there for the isolation of cases. Indeed, the question of extemporising additional hospital provision is under the consideration of the authority most concerned in the matter, the Metropolitan Asylums Board. While this is the state of things as regards small-pox in the metropolis, the chief provincial towns, in comparison, continue remarkably free from the disease. The cultivation of small-pox would appear to be becoming a specialty of the Local Authorities of London in combination with the Central Authorities (we use the plural term advisedly), and it is high time that we had some more definite information than we yet possess regarding the probable causes of these recurring outbreaks. For we are almost equally at sea whether we attempt to get at the true meaning of them viewed either in the light of facts in the natural history of the disease, or in the light of the proper application of the effectual means we have at our command for its restraint. It is in the latter, the practical light, the subject has the most pressing interest, an interest all the more urgent inasmuch as in solving the one question we shall go far to solve the other also.

And first let it be remarked that there is evidently a strange hesitation on the part of the Central Authority, or rather batch of Authorities, the Local Government Board, to whom we can alone look for information on the subject, either to give this information, or, assuming that the Board does not possess it (which is probably the fact), to get it. In the outbreak of small-pox in the metropolis preceding the one now threatening, the outbreak of 1876-78, several efforts were made in the House of Commons to obtain the information needed from the President of the Local Government Board. Motions set forth with a view of obtaining a thorough investigation of the beginnings of the outbreak of 1876-78 were met by a promise to put upon the table of the House papers showing the actual state of vaccination in the several districts of the metropolis. Not that this change of form mattered much, for to this day the promised papers have not been forthcoming, and there would appear to be little hope of even this imperfect instalment of what was sought for now seeing the light. The President of the Local Government Board was not unwilling that it should be known generally that the metropolitan population was the worst vaccinated in the kingdom, owing, it was said, to the migratory habits of a large section of it, and the exceptional draft of imperfectly vaccinated or unvaccinated persons from other parts of the country into it. He was willing that it should be inferred that it was to this imperfectly vaccinated state the metropolis owed the frequently recurring serious outbreaks of small-pox to which it was exposed. But he was careful to avoid enlightening the House as to the particular incidences of this imperfection in the different districts of the metropolis; and altogether both

he and his Department have displayed a marked desire not to ruffle the feelings of the local vaccination authorities, the Board of Guardians, by indiscreet disclosures. Yet, that there are disclosures to make about the way in which some of these authorities do their vaccination duties, and which it is desirable in the interest of the public should be made, is evident from the interviews which Dr. STEVENS, of the Medical Department of the Local Government Board, has recently had with Boards of Guardians in the east of the metropolis.

If the recurring outbreaks of small-pox in the metropolis are to be accepted as a gauge of its imperfectly vaccinated population (and in general terms we have little doubt that this is the case), it is to be inferred from the progress and character of the recent outbreaks that this imperfection is increasing rather than diminishing. Having regard to the circumstances under which public vaccination is carried out in the metropolis, there can be little wonder if such is the case. While professedly a public health measure, it is in reality a part of parochial administration, with all the narrow defects which attach to such administration. And notwithstanding that the central administration of public vaccination, both in its public health and parochial aspects, has been centred in the Local Government Board, the two aspects, in their administrative relations, are maintained as distinct as when they were attached to separate departments of Government. This want of a true union of the public health functions of the Board and its parochial functions is equally observed in every question with regard to small-pox in the metropolis, and underlies those serious difficulties which have sprung up in regard to hospitals for infectious sickness which are now impeding sanitary authorities in that matter.

Similarly the incoherent relations between the parochial and sanitary authorities of the metropolis and the Central Government contribute to the confusion and imperfection of action observed in public health matters. In fact, we see little hope of effectually dealing with the prevalence of small-pox and its recurring outbreaks, until, by a thorough investigation of the circumstances under which outbreaks like the one in progress occur, we are enabled to determine what part the shortcomings in the relations of the central to the local metropolitan governments play in the matter, and what share the deflections of local authorities, sanitary and parochial, take in their several duties in respect to small-pox. When these things are known we have little doubt remedies for insufficiencies will be forthcoming. Meanwhile, under the peculiar circumstances of the government of the metropolis, small-pox is undesignedly cultivated in a fashion from which smaller communities appear to be free, and which is a scandal equally to the Central Government and to the Local Government.

ACCIDENTS are often important factors in scientific discovery. They demonstrate the effect of combinations of influences which previous knowledge would not have led the investigator to combine, and they thus reveal, not rarely, previously unsuspected facts. Dr. BROWN-SÉQUARD accidentally dropped some chloroform on the skin of a healthy guinea-pig, in the position of the epileptogenic zone of animals artificially rendered epileptic. To his surprise,

the guinea-pig had a severe convulsive seizure. Recognising, with characteristic readiness, the suggestiveness of the fact, he commenced a series of experiments on cats, dogs, guinea-pigs, and rabbits, the results of which he has communicated to the Académie des Sciences.

If chloroform is dropped on to the skin of one of these animals a reflex contraction of the subcutaneous muscles is immediately produced. The respiration, as a rule, rapidly lessens, the temperature falls, the animal becomes lethargic and sinks upon its flank or back, without any attempt to resume the normal posture. A condition nearly that of sleep comes on, usually gradually, sometimes almost suddenly. Later, especially in guinea-pigs, tremor occurs in all four limbs, commencing in the hind limb on the side opposite to that on which the irritant liquid has been applied. The two hind limbs are drawn forward, the thighs strongly flexed on the abdomen; finally, general muscular relaxation occurs in many cases, especially in cats, which become then absolutely anæsthetic. A cat was exhibited in this condition, giving no other signs of life than feeble movements of the heart and respiration. After a quarter of an hour, an hour, or sometimes three or four hours, the animal wakes up, begins to move, and gradually returns to the normal condition.

Besides the tremors, convulsions are sometimes seen analogous to those of spinal epilepsy. Twice there was pleurosthotonos; in four animals, a cat and three guinea-pigs, there was rotation; and in two guinea-pigs, not epileptic, there was a violent attack of general epilepsy. Other interesting phenomena were also observed. Two cats became delirious. Two distinct forms of hemiplegia were seen: one cerebral, consisting in more or less complete loss of voluntary movement, with slight anæsthesia, in the limbs on the side irritated by the chloroform; the other spinal, with paralysis and hyperæsthesia in the limbs on the side of the irritation, and anæsthesia in the limbs on the opposite side. Paralysis of the two fore or of the two hind limbs sometimes occurred. These different paralyses were accompanied almost invariably with paralysis of half or the whole of the abdominal wall. The seat of the paralysis varies according to the part of the skin irritated. General hyperæsthesia often supervenes, in guinea-pigs especially, and lasts one or two days. The reflex action is more or less diminished, especially on the side on which the chloroform had been applied. The pupils become contracted in the cat, and dilated in the other animals, especially in the dog. Some animals presented complete paralysis of the intercostal muscles, others of the diaphragm. In two dogs and in several guinea-pigs, when the thorax was opened, it was found that one phrenic nerve had lost its excitability. The corresponding half of the diaphragm presented also a notable diminution in excitability. It was always the phrenic nerve and the half of the diaphragm on the side opposite to that on which the chloroform had been applied which were thus paralysed, while in many cases the phrenic nerve and half of the diaphragm on the side of the application were found to be more irritable than normal. The excitability of the nerves and muscles of the trunk and limbs was modified in a remarkable degree. An extremely feeble galvanic current was suffered to stimulate them, and after death, the irritability persisted for a much longer time than under normal

conditions. In guinea-pigs, for instance, the irritability persisted in the sciatic and brachial nerves three or four times as long as in animals the skin of which had not been irritated with chloroform. Another curious effect was the arrest of the exchange of material between the tissues and the blood, shown by a rapid fall in temperature, and pallor of the venous blood. Not only the peripheral nerves, but the spinal cord itself, acquired in many cases a remarkable morbid excitability. Moreover, a considerable congestion of the mesentery and of all the abdominal organs was found if the abdomen was opened before death. Lastly, two animals (guinea-pigs) died suddenly immediately the chloroform was applied to the skin—one by arrest of the heart, respiration continuing for some seconds, the other by simultaneous arrest of the heart, respiration, and of the exchange between the tissues and the blood.

This list of effects is a long and startling one, and, coming from a less eminent and experienced investigator, would probably be received with incredulity. From Dr. BROWN-SÉQUARD, however, we cannot but accept the facts, however mysterious may be their explanation. He points out that they cannot be regarded as the result of the entrance of chloroform into the blood. Very little of the vapour could possibly be inhaled, and chloroform in the blood would only account for a small part of these varied consequences. The only explanation which is offered is that they are due to an effect on the nerve-centres of a special irritation of the nerves of this region of the skin.

In a subsequent communication Dr. BROWN-SÉQUARD has described some experiments made with the object of verifying the hypothesis that these results are produced through the agency of the cutaneous nerves. In several guinea-pigs he divided the spinal cord transversely at the level of the ninth dorsal vertebra, and then applied chloroform on one side of the sacrum and abdomen—that is, to the parts receiving their nerve supply from the portion of the spinal cord which had been separated from the brain. In other guinea-pigs, the spinal cord having been divided at the same level, he applied chloroform to the side of the thorax and neck. If the remarkable effects of the chloroform be produced by the agency of the blood, it is clear that they should occur irrespective of the position of the application in regard to the divided cord. But they were absent in the first series of guinea-pigs, and present in the second. Hence, it seems certain that the effect is not produced by means of the blood, but by the agency of the nervous system. Several interesting facts were observed in these experiments. When the chloroform was applied to the parts behind the section of the cord, there was no congestion of the abdominal organs, such as invariably occurs when chloroform is applied to the skin if the spinal cord has not been divided. It occurred, nevertheless, when the chloroform was applied to the skin of the neck and thorax above the level at which the cord was divided, no doubt through the agency of the splanchnic nerves. It was found, however, that the application behind the section inhibits the reflex action of the dorso-lumbar part of the cord; and that its spinal influence on muscular tonicity is also lost, so that the abdomen becomes distended on that side, much more than on the opposite side.

In other experiments the transmission of the effect to the brain was investigated in cases of hemisection of the cord

in the cervical region. After the division of the cord on the right side, with the usual effect of causing hyperæsthesia of the right half of the body and anæsthesia in the left half, chloroform was applied in some cases to the right, in others to the left side. In the former the cerebral symptoms rapidly supervened, of the full character above described. On the other hand, in the second series, when the application was made to the anæsthetic side, the phenomena were either absent or tardy in their appearance, and the congestion of the abdominal viscera was absent. Another point investigated was, whether it is possible to kill an animal in perfect health by the application of chloroform to the skin. He found that whenever the liquid has produced loss of consciousness, anæsthesia, and a notable fall in temperature, death occurs with certainty if the liquid is still applied to the skin.

Certainly the annals of experimental pathology scarcely contain another example of a series of effects so profound from a cause so slight. Dr. BROWN-SÉQUARD does not point out the bearings of his experiments on therapeutics, but they are sufficiently obvious and important. It is evident that the remarkable anodyne effect of chloroform and other agents applied to the skin in cases of neuralgia, even of central origin, may find their explanation in the influence which he has discovered and investigated in these most interesting observations, and which can doubtless be produced in varying degree throughout the animal kingdom.

It must not be supposed from the fact that we have for some time past preserved a purposed silence on the subject of the private asylum system and Lunacy Law Reform, that the question originally raised by ourselves, and of late years freely discussed, with more or less wisdom, in the lay press, is not still engaging our attention. We are, in truth, pursuing researches of a very exhaustive kind in ways and by agencies more likely to give us a full and clear view of the subject than any we have previously been able to employ. It would be premature to say more at present, but in justice to the profession, and more particularly that section of it which is engaged in asylum practice, it is right to state that our long-standing conviction is confirmed, and we must adhere to an opinion which has to a great extent placed us at variance with the majority of Lunacy Law reformers—namely, that it is the system, rather than the way in which it is worked, or the persons working it, which most urgently demands the impartial scrutiny of the Legislature. It will be exceedingly unfortunate if the subject is not discussed on a proposal made by the Government during the approaching session; and our immediate object in reopening the question in these columns at this period of the recess is to point out the need of at once pressing the matter on the attention of the Cabinet.

The glaring and more mischievous faults of the present arrangements are specifically three: First, the loose mode of *certifying*. It is as true now as it ever was that any two medical practitioners—neither of whom need have heard a lecture on insanity, read a page in any work on the subject, been asked a question at any examination, or even seen a case of lunacy—can at will, and after a single visit, without consultation, or time or opportunity for reflection, sign a certificate which in many instances must be worse than a

death warrant, branding the person so certified with a life-long mark of social disability. It is, we protest, monstrous that the certified opinion of any practitioner of the art of Physic should have the force of a legal warrant for imprisonment; and that it should deprive the person named therein of personal liberty, self-support, and all that makes life pleasurable, without appeal. It is not necessary that any such certificate should be signed, and if it were otherwise it would not be fair to ask medical men to sign it. We are concerned with the study and amelioration of disease; and we do not desire to be interrupted in our scientific pursuits to perform this most unsavoury service. The notion that “certifying” patients insane offers the smallest safeguard to the public is purely chimerical. The protection needed is an efficient and sufficient inspection of asylums such as this country has never yet enjoyed. How long public opinion will rest content with the formal system of visiting carried out by the Board of Commissioners in Lunacy as at present constituted we will not venture to predict; but the fact cannot be gainsaid that, except in so far as the existence of a Commission in Lunacy results in the publication of systematic reports, and therefore keeps the subject of asylum-management before the public, it is practically useless. No more restraint is necessary in the treatment of a case of lunacy than in the management of a case of febrile excitement or delirium tremens. We are not asked to certify in the one class of cases; why should we be in the other? The safeguard against sane persons being put away in asylums must be the perpetual surveillance of these establishments, and such an arrangement as shall make those who act as “keepers” public officers publicly responsible.

This leads us to the second point—namely, the *private-asylum system*. It is, we once again assert, opposed to all the interests of law and of public safety that the power to imprison any person, sane or insane, self-controlled or carried away by an idea, should be entrusted to private persons. We have abolished sponging-houses for debtors; it remains to put an end to the system of allowing private persons to keep lock-up houses for the insane, as a matter of commercial business and in the way of profit. Nothing short of a complete and sweeping change of this system will suffice. Asylums ought to be put on the footing of *hospitals* so far as the treatment of mental disease is concerned, and the individuals to whose discretion the management is committed should be on the footing of public officers, gaining nothing by the detention or the discharge of their patients, either in money or prestige. It is useless to mince matters. The public asylums everywhere have their faults; they are too large, too palatial, wholly unlike the “homes” of their inmates; and they are conducted less as *hospitals* than as refuges. All these evils are deplorable, and they mar or hinder good medical work. Meanwhile, however, the private asylums are incomparably worse, not in themselves or as establishments, but because they rest on a wrong foundation, are organised on a bad principle, and place the medical man in charge—whether he be the proprietor or only *employé*—in a false and humiliating position. He cannot keep his patients long enough to assure their recovery without being suspected of acting from unworthy motives, and he cannot discharge them without subjecting his establishment to a loss which may or may not

be speedily compensated by the admission of new cases, but which is, as far as it goes, a pecuniary sacrifice to the business of the "boarding-house." It is wrong that this should be so, and nothing but harm can come of it.

The third of the three cardinal evils to which we have alluded lies in the *difficulty of getting patients out of asylums* when once they have been incarcerated, whether their admission was necessary or made in error. No assurances given by the Commissioners on this point can, or should, have the smallest weight with the public. What the Board means when it asserts that few, if any, cases of mistake have come under its notice is simply that, with very rare exceptions, the certificates sent to the Commissioners are fully made out and technically satisfactory, and that the keepers of asylums do not often (!) complain to them of patients being improperly placed in their establishments. It would be strange, indeed, if matters were not satisfactory, and if the most unqualified assurances were not forthcoming in respect to both these particulars. As a matter of fact, the Commissioners in Lunacy do not even see—as the official eye is gifted to see—anything like the "total" of patients that pass through these asylums. There are large middle-class institutions which, as the official Reports show, are not "visited" more than once a year, and not always thus frequently, whereas the majority of the cases "discharged on recovery" or "transferred," or who have "died" in asylums of all classes, reach the termination of their imprisonment, in one or other of these ways, "within six months"! We are speaking of the *system* with the general average of its consequence. We protest it is wholly bad. The difficulty in getting patients out of asylums is the fruit of the facility which exists for getting them in. Until the law relating to "certifying" is repealed and reconstructed there can be no satisfactory and sufficient change in the condition of the insane as regards the probability of their prompt discharge on recovery, or the frank avowal that an error has been made, and passing disturbance mistaken for permanent disease.

We will not pursue the subject further into detail on the present occasion, but we are anxious it should be recognised that, so far as we are concerned, the subject is not shelved. We shall not rest content until the whole question has been amply discussed in Parliament, and the profession and the public have had all the facts set clearly before them, and had their say.

THE last meeting of the Council for 1880 of the Metropolitan Hospital Sunday Fund was held on Tuesday at the Mansion House, under very favourable auspices, which call for a few words of notice. The first thing to observe in reviewing the history of the Fund this year is that a larger collection has been realised than on any previous year. In 1874 the total of the Fund was £29,936; in the present year it reached £30,423. Not only was there a considerable increase in the individual donations, but also in the number of contributing congregations. We may venture to hope that with further improvement in the commercial condition of the country the amount of the collection will yet further increase. Two or three other points in the history of the Fund for the year augur well for the future. The unsectarian character of the Fund has been well shown by the vindication of Rule 4. This rule, requiring that every in-

stitution shall be managed by a duly-appointed Committee, is of the utmost importance. It was elicited at the meeting on Tuesday that other institutions besides the Eastbourne Convalescent Home—which, by the way, has in this respect amended its constitution—are out of harmony with Rule 4. Sir SYDNEY WATERLOW explained that an intimation to this effect will be made to the institutions in question, so that they may have ample time before the distribution of next year to put themselves into the position of public institutions managed on public principles. It is evident that institutions managed by two or three persons, without meetings of subscribers and without a committee elected by and at such meetings, are, whatever their usefulness, only private establishments. Another point in respect of which the Hospital Sunday Fund is working well is in the difficult matter of Surgical Appliances. The charities which profess to provide these appliances are known to require a number of letters from subscribers, whose money value represents the value of the instrument or appliance required, so that, as in an instance stated at the meeting on Tuesday, a man requiring an artificial leg may have to travel all over the town for fifty letters before he can obtain that necessary adjunct. Last year it was resolved to set aside 1 per cent. of the Hospital Sunday Fund for the prompt relief of such cases. This has worked so well that the Council unanimously decided henceforth to set aside 2 per cent. of the Fund.

Finally, the Fund will be continued for the next twelve months under the most cordial support and sanction of the Lord Mayor, Alderman MCARTHUR, who, on Tuesday, expressed a strong wish that it should again be accommodated with quarters in the Mansion House, as at the beginning. Ever since the Fund has been obliged to have its own offices it has been favoured with the kind interest of two Lord Mayors and the use of the Mansion House for council meetings. But it will now again have its local habitation there with all the advantage which such an association gives it. The Council naturally passed a very warm vote of thanks to the Lord Mayor for this marked kindness, and will best show their appreciation of it by redoubled efforts to increase the Fund and maintain its impartial administration. We thus leave the Fund for the present, not without satisfaction in remembering that we ourselves made some special effort before the collection to emphasise the needs of the hospitals of London and the duties of London churches in reference thereto. The annual meeting of the constituency of the Fund is fixed for Dec. 20th.

Annotations.

"No quid nimis."

THE MEDICAL CURRICULUM.

NOTWITHSTANDING all that has been said and written and proposed during the past ten years, the problem of medical education still remains unsolved. Indeed, it would seem that each year it becomes more intricate and complicated. Numberless schemes of reform have, from time to time, been proposed, but few of them have had a really practical basis. Abuse has been lavish and general; at one time the student has been blamed, at another the teacher, and nearly always the examiner. The truth is, the system as a whole is wrong, and none of its parts work smoothly.

In another column will be found a sensible, though startling, proposal by an experienced teacher and examiner. Mr. Savory very properly ascribes the chief defects of the existing system of medical education to the fact that too much is attempted in the comparatively brief medical curriculum. Three remedies are available: either to lessen the number of subjects, or to lower the standard of attainments, or to prolong the period of study. Of these three courses only the last can be regarded as finally satisfactory. Few persons will maintain that the medical student or practitioner can know or learn too much. Each and every subject included within the curriculum is more or less essential to a complete education. What is needed is, an adequate prolongation of the compulsory course of study. Nor is this recommendation so much of an innovation as might at first sight appear. In the days of apprenticeship a course of training and education extending over six or seven years was the rule; it is only since the system of apprenticeship has grown into gradual disuse that the time for study has been clandestinely and almost illegitimately curtailed. The time formerly spent in pupilage has been saved without any corresponding extension of that passed at a medical school. Failing a *bona fide* apprenticeship (and there is much to be said both for and against this), six or seven years at a medical school cannot be held by reasonable persons to be too long for the professed elaborate education of the medical student of modern times.

THE EXCRETION OF INDICAN.

MUCH attention has lately been directed to the mode of origin of a substance which has been demonstrated to be one of the normal constituents of urine—indican. Its nature, and the conditions of its excretion, have been the subject of investigation by many writers since Schunk, in 1857, called attention to it, and the facts which have been ascertained have been well summarised and added to by Dr. H. N. Heineman in the *Archives of Medicine* for August. Indican has been separated from the urine in the form of white shining masses, by Bauman and Brieger, who class it in the aromatic series, to which phenol and benzol belong. It is a compound body, composed of indigo-blue, indigo-red, indigo-glucin, leucin, and acids. Nevertheless it does not give any colour to the urine, except in rare instances, and then the colouration is due to decomposition by a ferment, either before or after being voided from the bladder. A blue tint is observed, due to the liberation of indigo-blue, crystals of which may be found in the urine. The ease with which it undergoes this decomposition renders its detection in the urine easy, and also furnishes a means of its quantitative estimation. Hoppe-Seyler has found that the amount of indigo-blue produced is definitely proportioned to the amount of indican. Hence, if the indican is decomposed by hydrochloric acid, and the indigo-blue dissolved out in chloroform, the tint of the solution affords an index to the amount of indican. It is usual to add some calcium hypochlorite to the solution, which completes the decomposition of the indican, and intensifies the colour.

The source of indican, according to the researches of Jaffe, Kuhne, and Salkowski, appears to be a nitrogenous body called "indol"—the substance to which the peculiar odour of faeces is due. It is a product of the decomposition of albuminous substances when acted upon in the intestine by the pancreatic juices. Christiani has shown that if indol is injected hypodermically into the lower animals, the excretion of indican is thereby increased. Ewald, in a case of artificial anus, withdrew the secretions from the upper part of the small intestine, and found that then no indican appeared in the urine. The excretion has been found to be increased by a prolonged and exclusive meat diet. It is possible that it is derived also from other

sources, and it is conjectured that some may come from the blood, which furnishes, as far as we know, all the other colouring matters of the body. Many diseases which are attended with a diminution in the hæmoglobin of the blood, cause also an increase in the excretion of indican, and the two may be observed to coincide in time. It is thus evident that we have much more yet to learn regarding this substance.

The new observations which have been supplied by Dr. Heineman constitute an important addition to our knowledge. He has examined the excretion in upwards of 200 cases, of which 150 were cases of disease. He has added these to the cases examined by Hoppe-Seyler, Senator, and Hinnige, making a total of nearly 400 from which to draw conclusions. One hundred and forty-nine of the observations were on the excretion in health, and indican was found in all but 14, that is, in about 90 per cent. In nearly half Heineman's cases there was an increase above the average, and in one-fifth there was a marked increase. It seems, therefore, probable that the kind of diet must be taken into consideration in every case. Certain diseased conditions were found to produce a decided increase. The most marked excess was found in the diseases which affect the alimentary canal, and especially the small intestine, whether local diseases or general diseases with a local lesion. There was a marked increase, for instance, in dyspepsia, gastro-duodenitis, chronic constipation, intussusception, diarrhoea, peritonitis, cholera, lead-poisoning, and typhoid fever. In diseases causing inanition, phthisis, and scrofulous bone disease, an increase is also found. Although some diseases in which there is a reduction in the hæmoglobin of the blood cause an increase, there are curious, and at present mysterious, variations in the effect of diseases of this class. Thus, malaria, syphilis, rheumatism, alcoholism, progressive anæmia, and chlorosis, even when the blood-change is profound, do not always cause an increase in the excretion of indican. Further observations on this class of disease are needed to ascertain the conditions under which the excretion varies. There is a marked increase in certain nervous disorders—insanity, epilepsy, Addison's disease, progressive muscular atrophy, and paraplegia, and also cases of disordered function of the kidneys, as in chronic Bright's disease. The diseases, however, in which the most uniform and marked increase is met with are internal malignant tumours—sarcoma and carcinoma.

Theoretical reasons have been offered in explanation of these pathological variations, but our knowledge is at present too inadequate to furnish grounds for safe hypothesis. A suggested explanation of the increase in peritonitis, constipation, &c., which has been founded on the experiments of Jaffe, seems probable. He found that when the small intestine was tied the amount of indican in the urine was increased. This seems to show that a mere retardation of peristalsis may, by promoting the absorption of indol, increase the indican. Hinnige suggested that other diseases act through the nervous system, and produce a change in the nature of the pancreatic secretions, but it has been shown by Brieger that indol may be produced without the agency of the pancreatic juices, and by Senator that it is unquestionably a product of decomposition. It is possible that observations on the excretion under the influence of various drugs may throw further light on its origin.

THE LONDON FEVER HOSPITAL.

THE appeal of the noble President of the London Fever Hospital should not be forgotten as the season of Christmas arrives. Only medical men, perhaps, know the useful work which this hospital does, how it sends its ambulance for, and opens its doors to receive, fever-stricken servants, or members of families, and so not only provides for them, but

delivers the remaining members of such families from terrible risks, and the general public from wider extensions of disease. It is impossible to overstate the convenience and utility of this institution. Its claim on the public is not the less strong that it takes a payment for each patient; for those in the general wards two guineas, their cost to the hospital being eight; and for patients in private wards three guineas a week, which just suffices to pay their cost. It will thus be seen that the hospital is a charity of the very best kind. It charges patients, but it makes no profit. So far from doing this the noble Duke tells us that for the last six years the hospital has had to be carried on by the annual sale of about £2000 of its funded property. It is easy to see what the end of such a state of matters must be if the benevolent public does not step in with aid. There is one most tempting rule of this fund—viz., that a governor paying a guinea a year can have a servant admitted without charge at the discretion of the committee. We most heartily commend the urgent appeal of the Duke of Devonshire to the wise and benevolent of the public.

EFFECTS OF CARBONIC OXIDE ON ANIMALS.

At the last meeting of the Académie des Sciences, M. Gréchant read a paper giving the results of a series of experiments he has made upon the absorption of carbonic oxide by the living animal, and showing how he has been enabled to determine exactly the smallest proportion of this gas which proves fatal to different animals. He states that he first introduced into a large gasometer a homogeneous mixture of air and carbonic oxide, containing 1-400th of the latter gas. A dog weighing 15 lb. was compelled, by a properly arranged apparatus, to breathe this for the space of fifty-six minutes. At the expiration of this period, the muzzle being taken off, it remained lying for a few moments, then rose and walked about. A drop of the blood, examined with the spectroscope, showed that the bands of absorption of oxycarbonised blood were present. On the following day the same animal was made to respire a rather stronger mixture, containing 1-350th of the carbonic oxide gas; the experiment lasted forty-five minutes. The animal remained lying, and was only able to rise after the lapse of some minutes. On the following day, again, a mixture containing 1-300th of carbonic oxide was supplied to it. At the expiration of fifty minutes the respiratory movements stopped. The animal died without the least agitation. It had respired 146 litres of the mixture. One hundred cubic centimetres of blood taken from the inferior vena cava was only able to absorb 6·8 cc. of oxygen, proving that the hæmoglobin was almost completely oxycarbonised, and hence that for the dog the precise lethal dose was 1-300th of carbonic oxide. In experiments on another animal of the same species and weight the lethal dose was found to be 1-250th of the gas. This difference seems to explain how it is that when two persons are exposed to an atmosphere impregnated with carbonic oxide one may die whilst the other survives.

M. Gréchant finds from similar experiments on rabbits, exposing them successively to mixtures of air and carbonic oxide, containing 1-500th, 1-400th, 1-300th, 1-200th, and 1-100th of carbonic oxide, that even the last high proportion does not prove fatal to them. A mixture containing 1-70th was breathed for forty-eight minutes; the animal remained resting on its side for some minutes, but then rose and moved about. The proportion of 1-60th, however, proves fatal to the rabbit. It hence appears that great differences exist between different species of animals in regard to their resisting power to the action of the gas. In experiments with a stove without a chimney M. Gréchant finds that the combustion of two kilos of carbon of wood, in a chamber having a cubic capacity of forty-five metres, was sufficient to partially poison a dog to such an extent that

the absorbing power of the blood for oxygen, which normally amounts to 23·2 cc. per 100 cc. after two hours and a half was only able to absorb 12·4 cc. of oxygen, so that 10·2 cc. of oxide of carbon had been fixed by each 100 cc. of blood. Under these conditions a guinea-pig would have died, since 1-500th proves fatal to that animal.

SCARLET FEVER IN CHRIST'S HOSPITAL.

CHRIST'S HOSPITAL (the Blue Coat School), with its 700 and odd inmates, is now suffering from scarlet fever, after a long immunity from any considerable prevalence of the disease. In fact, during the ten years 1870-79 in no year did the number of cases which occurred in the school exceed four (1874 and 1877), while in seven years one case only happened in each year, and two cases in one year (1870). But on the 11th of the past month (November) of the present year four cases of scarlet fever took place among the boys, followed by six more in the next three days. From the 15th to the 20th there were no fresh cases; then from the 21st to the 25th thirteen more boys sickened of the disease—apparently showing an incubation period of about seven to ten days. The infection appears to have been introduced into the school from the playground, the most careful inquiry having failed to show any more probable source. It has been determined by the school authorities to leave the decision of retaining the healthy children in the school or sending them home, to their parents, and a circular has been issued to this effect. As a consequence, a large number of the children—about 250, we understand—has been withdrawn. We trust that the school authorities have taken means to insure that they receive information as to the subsequent history of these children in respect to scarlet fever. It has been long held of this disease that the dispersion of schools under these circumstances contributed to spread the infection more widely and more speedily through the country. From that point of view the future history of the children who have gone home will be of great interest, not only as furnishing information with regard to the doubtful point in preventive medicine, but as a guidance to the school authorities, should they unhappily be placed in a similar unfortunate position in the future. The type of the malady in the hospital is, we are glad to learn, of the mildest, while the scholars remaining are placed under the most favourable circumstances for avoiding the disease, or such as may contract it for passing through its course with least detriment to themselves.

THE LATE DR. HUDSON.

At a meeting of the Professors of the School of Physic, held on Nov. 25th, it was unanimously resolved, "That the Professors of the School of Physic in Ireland desire to place on record their sense of the great loss which medical science in Ireland has sustained by the recent death of Alfred Hudson, M.D., late Regius Professor of Physic in the University of Dublin. The Professors further desire to convey to Dr. Hudson's widow and brother their hearty sympathy with them in their present trial."

At a special meeting of the directors of the City of Dublin Hospital, held last week, the following resolution was unanimously adopted:—"That this Board has heard with deep sorrow of the death of Dr. Alfred Hudson, Physician-in-Ordinary to the Queen in Ireland, the consulting physician of this hospital, and they beg to convey to Mrs. Hudson their expression of sympathy and regret."

At the opening meeting of the Dublin Obstetrical Society on Saturday last, the Rev. Dr. Haughton referred to the loss which the country and profession had sustained in the death of Dr. Hudson, and moved, "That the Obstetrical Society of Dublin desire to record their sense of the loss that medical

science has sustained in the death of Dr. Alfred Hudson, and to convey to his widow and brother their warm sympathy in their deep bereavement." Dr. Kidd seconded the resolution, and said they were all deeply sensible of the loss the public and the profession had sustained by the death of so able a man. The resolution was passed in silence, and the secretary was directed to forward it to the family of the deceased gentleman.

The Committee of the Meath Hospital have also passed a resolution sympathising with Dr. Hudson's family in their bereavement.

THE EFFECT OF EXERTION ON TEMPERATURE.

DR. BONNAL of Nice has been experimenting on the effect of muscular exercise on the temperature of the body. The observations were made on four individuals, the temperature being taken in the axilla, popliteal space, groin, foot, hand, mouth, and rectum. The investigation has been prosecuted during four years, and the conclusions reached are the following:—All muscular exercise, even if of short duration, raises the temperature of the rectum, rarely, however, to a point exceeding 101° F.; but the rise occurs invariably, at whatever hour the exercise is taken, whether before or after rest, and independently of age, sex, and meteorological conditions. The effect bears no relation in degree to the duration of the exercise, or to the apparent fatigue. The influence of the same exertion, under identical conditions, varies in different individuals, and in the same individual at different times. The physical altitude, the state of the atmosphere, and the amount of clothes, exercise, as might be anticipated, a marked influence on the degree, and especially on the rapidity, of the rectal rise in temperature. On the other hand, however, the absence or abundance of perspiration has no appreciable influence on the variations in temperature during movement. Rest, after a given exercise, always determines a fall in the rectal temperature, more considerable and more rapid the shorter the exercise. All exertion which causes a great acceleration of the pulse and respiration lowers the peripheral temperature (mouth, axilla, groin), but the fall is immediately recovered from on rest, the rectal and peripheral temperatures becoming equalised, or resuming their normal difference—about two-thirds of a degree Fahrenheit. The greatest elevation by exercise which was met with amounted to 103·2° F., in the case of a celebrated runner, aged thirty-one years, who had just run eleven miles in an hour and a half without stopping, and without any other effect than an elevation of the pulse to 145. If the rectal temperature is below 98·6°, a moderate exertion, such as a gentle walk of a mile on level ground, raises the temperature up to the normal, even though the necessary rise amounts to 1½° F. But if the temperature is already above 98·6°, the same exercise will not raise the temperature more than ·4° or ·8° F. In a rapid ascent the greatest elevation of temperature almost always occurs during the first half hour; if the ascent is continued, the temperature may remain stationary, may be raised ·2°, or may fall ·2° or ·3°. Some other observations which corroborate the fact that gymnastic exercises cause a rise of temperature are not of special interest. The account of the investigations has been communicated to the French Académie des Sciences.

A JURY ON UNQUALIFIED ASSISTANTS.

AT an inquest touching the cause of death of George Beighton, of Marsh Gate, Doncaster, the jury found that he died of erysipelas, and expressed their disapproval of medical men leaving unqualified persons in charge of their patients. The coroner stated that he had received a letter from Mr. Jessop, of Leeds, giving the assistant, Mr. David

Allison Bradbury, a very good character. Doubtless Mr. Jessop had good grounds for doing this; but it is nevertheless indefensible for a surgeon to leave an unqualified *locum tenens* in charge for three weeks. Beighton, in driving to Walworth, in a state of intoxication, fell from his cart and incurred a severe bruise of the right temple. Mr. Bradbury, thinking, as he said, there was pus, made an incision, which bled more or less, according to the evidence of the deceased's wife, till death. It is not clear whether the man died of erysipelas or hæmorrhage. Mr. Bradbury says there were no veins in the neighbourhood of his incision! But one thing is clear, as the jury said, that unqualified assistants should not be left in charge of patients for any length of time.

PROFESSOR LISTER.

IN his presidential address at the Royal Society on St. Andrew's Day (Nov. 30th), Mr. Spottiswoode thus referred to the work of Professor Lister with which his name and fame are more particularly associated:—

"One Royal Medal has been awarded to Professor Joseph Lister, F.R.S. Mr. Lister's claims to the honour of a Royal Medal are based upon his numerous and valuable contributions to physiological and biological science during the last thirty years. Condensed into a single sentence, the merit of Mr. Lister consists in the generalisation to living matter of the results obtained by Schwann and Pasteur with dead matter. He began with cases of compound fracture and with abscesses. In simple fracture the wound is internal, the uninjured skin forming a protecting envelope. Here nature works the cure after the proper setting of the injured parts. In compound fracture, on the other hand, the wound extends to the surface, where it comes in contact with the air; and here the operator can never be sure that the most consummate skill will not be neutralised by subsequent putrefaction. In the earliest of his published communications, Mr. Lister clearly enunciates, and illustrates by cases of a very impressive character, the scientific principles upon which the antiseptic system rests. He refers to the researches of Pasteur, and shows their bearing upon surgery. He points to the representative fact then known, but unexplained, that when a lung is wounded by a fractured rib, though the blood is copiously mixed with air, no inflammatory disturbance supervenes; while an external wound penetrating the chest, if it remains open, infallibly causes dangerous suppurative pleurisy. In the latter case the blood and serum are decomposed by the microscopic progeny of the germs which enter with the air; in the former case the air is filtered in the bronchial tubes, and all solid particles are arrested. Three years subsequently this inference of Professor Lister was shown to be capable of experimental demonstration."

"NUTRICINE."

A NEW method of preparation and preservation of meat in a small bulk has been described to the Paris Académie des Sciences by M. Ed. Moride. The details of the process are not published, and it is not, therefore, possible to form a critical estimate of its practical character, but it promises to be of value if the statements of its inventor can be relied upon. It consists in treating, in special apparatus, finely-divided meat, together with certain "nitrogenised alimentary substances," which have the property of absorbing the constituent water of the meat, and perhaps of forming with the meat certain organic compounds, still undetermined; the whole is then dried at a low temperature and powdered. There results a yellowish powder of an agreeable taste, which will keep indefinitely if not exposed to moisture or to a great heat. By mixing it with mucilage, albumen, or fats, tablets or cubes of any size can be prepared for various culinary or nutritive purposes. The powder is said to contain all the elements of raw meat in their natural condition, so that blood thus treated preserves all its properties of solubility, colour, and coagulation on heating. Nevertheless, the solution in cold water of the prepared blood does not decompose for several

days. In the preparation the meat is not cooked, and so it is in a state ready for digestion. Weight for weight it is more nutritious than meat, since it contains no excess of fat and no tendinous structures, and, moreover, the three-fourths of water removed are replaced by the same proportion of slightly cooked farinaceous substances, which contain, besides hydrocarbons, 2 per cent. of nitrogen. Hence nutrine contains 5 per cent. of nitrogen; whereas the meat from which it was prepared contains only 4 per cent. It is suggested that, by this process, the refuse of slaughter-houses will yield a useful food for dogs, pigs, and fowls.

SHAM PROVIDENT DISPENSARIES AND UNQUALIFIED ASSISTANTS.

THE *Evening Standard* gives a correspondent an opportunity of warning the public against what he calls sham provident dispensaries, basing his charges on reports of two inquests which had recently appeared in our contemporary, the facts of which he thus summarises:—"Two women are deceived into joining a so-called provident dispensary, are treated by an unqualified man, and die under circumstances necessitating an inquest." There can be no reasonable doubt that the writer in the *Standard* warns those who would be provident and who go to cheap dispensaries against a real danger. It cannot be denied that a very large number of these dispensaries are conducted by unqualified persons, though nominally belonging to registered practitioners. If such practices go much further, it will be the duty of coroners to hold still more frequent inquests, and to bring the facts under the notice of the Government. Meantime sensible people should ask themselves how it is possible to be supplied with educated opinion and medicines for a week for a sum that would not pay for half a week's beer.

THE ROYAL HOSPITAL FOR INCURABLES.

THIS hospital held its annual meeting a few days ago at the Cannon-street Hotel, and had the benefit of a little criticism from one of the subscribers, Mr. Alsagar Hay Hill. Critics are an unpopular class at public meetings of charities. And so Mr. Hill seemed to prove. Nevertheless we think this hospital would do well to give a little more heed to reasonable criticisms and complaints. To take, for example, even the rough figures of expenditure and work—these would really be the better for some explanation. Thus we have legacies from £2471 to 19 guineas in the course of the year. The receipts for the year, with the balance from last year, were £25,108 17s. This is a very large sum to have to use. It is expended on 183 inmates and 419 pensioners; or, to speak more strictly, £23,744 7s. 4d. was expended. If we allow twenty pounds each to the pensioners, this leaves £15,364 to be spent on 183 inmates, or over eighty-three pounds a year for each. This seems to us a large sum for cases housed together. When, in connexion with this large expenditure, we consider the costly mode of election and admission, we cannot but regret that a hospital with so good an object should be so open to criticism and so little thankful for it.

EDWARD GOODEVE MEMORIAL FUND.

A MEETING of the friends of the late Deputy Inspector-General Edward Goodeve, M.B. Lond., Honorary Physician to the Queen, was held at Connaught-square, Hyde-park, London, on November 18th, Deputy Inspector-General F. J. Mouat in the chair, at which it was unanimously resolved—"That subscriptions be invited for the purpose of raising an 'Edward Goodeve Memorial Fund,' to be devoted to the purchase of a marble bust for the Calcutta Medical College, and the endowment of a Scholarship in connexion with the Professorship of Medicine in that school."

The following gentlemen were nominated as an executive committee to carry the resolution into effect:—Inspector-General J. Forsyth, C.B., Q.H.P. (President); Surgeon-General Sir Joseph Fayrer, M.D., F.R.S., K.C.S.I.; Surgeon-Major A. Grant, F.R.C.S., Q.H.S.; J. H. Matthews, Esq.; Deputy Surgeon-General S. B. Partridge, F.R.C.S. (Honorary Treasurer). The General Committee is to consist of Dr. Goodeve's former colleagues at the Medical College and such other friends as may be willing to act.

Subscriptions (not to exceed two guineas) to the fund may be paid to Messrs. Grindlay and Co., 55, Parliament-street, Westminster; to Messrs. Grindlay and Co., Clive-street, Calcutta; or to the hon. treasurer, Deputy Surgeon-General S. B. Partridge, Thicket Lodge, Thicket-road, Anerley, London, S.E.

THE BIRKENHEAD SEWER ACCIDENT.

THE adjourned inquest on the death which occurred in the Birkenhead sewers a short time ago was held on the 25th ult. Dr. Vacher, the medical officer of health, gave evidence to the effect that the deceased labourer had lost his life from the inhalation of sulphide of ammonium generated by the sewage, and he expressed the opinion that the ventilating openings in the sewers were too far apart—in other words, that the sewers were insufficiently ventilated. It appeared from other evidence that the sewers contained much deposit, and needed frequent periodical flushings, which had not been given. The jury gave a verdict in accordance with Dr. Vacher's evidence of the cause of death, and added the following presentment:—"We consider the Corporation have been guilty of great neglect in permitting such an accumulation of sludge in the sewer as has been elicited in evidence, and that such a deposit ought not at any time to be allowed to exist."

VETERINARY SURGERY.

WE have much pleasure in learning that, in the forthcoming session of Parliament, a Bill is to be introduced for the protection of the title of Veterinary Surgeon, conferred by two separate charters on the graduates of the Royal College of Veterinary Surgeons, the first dating so long ago as 1844. Such an Act is greatly needed, as the country swarms with men who have no right whatever to the title—indeed, anyone may adopt it with impunity. People perfectly unacquainted with medicine or surgery—coachmen, grooms, farriers, blacksmiths, &c.—dub themselves Veterinary Surgeons, and even Members of the Royal College of Veterinary Surgeons; and thus not only impose on the public and cause serious loss, but cruelly maltreat animals. It is astonishing the Royal College of Veterinary Surgeons has not moved in the matter long ago; but we are gratified to find that the present president, Mr. George Fleming, Army Veterinary Inspector, has taken up the question, and we may be sure nothing will be left undone to carry it to a successful termination. It is one in which the medical profession has an interest, and it should receive their support.

RABIES IN IRELAND.

RABIES still manifests itself in Ireland, and it is probably extending. On September 3rd an artillery horse had to be destroyed at Kilkenny in consequence of the disease. It had been bitten on the nose at the Curragh camp on July 4th by a mad dog, which ran amuck among the horses and people there. A characteristic symptom presented by the poor creature was intense itching at the seat of injury. On November 21st great excitement was caused at Kilmainham by the rushing about of a mad dog, which was not killed until it had succeeded in biting two

men and a dog. One of the men, a labourer, it seized by the thumb. Then dashing into Island Bridge barracks past the sentry, it entered the quarters of Lieutenant Aylmer, of the 19th Hussars, whom it caught by the left arm, inflicting a severe bite. It was eventually destroyed by a police constable.

PATHOLOGICAL SOCIETY OF LONDON.

THE Debate on Rickets will be resumed at the meeting of the Pathological Society on Tuesday next. Specimens of foetal rickets will be shown by Dr. Barlow and Mr. Shattock, and microscopical specimens by Dr. Turner. Drs. Dickinson, Gee, Moore, Baxter, and Longhurst, and Messrs. Haward, Parker, and Lucas are expected to speak; there is thus hardly any prospect of bringing the discussion to a close on this occasion.

THE usefulness of the object aimed at by the St. John Ambulance Association—that, namely, of imparting instruction to public servants and others in the best modes of affording first aid to the wounded—appears to be receiving hearty recognition all over the country. Dr. Palk, surgeon to the Southampton Borough Police, has been lecturing on the subject; Dr. Stiven, of Sunderland, has inaugurated an ambulance class at Ferry-hill; and the movement seems to have gained great popularity in Dublin, where Major Duncan, in the presence of the Lord Mayor, a few days since presented certificates to a large number of successful candidates.

SIR BENJAMIN COLLINS BRODIE, Bart. (son of the late distinguished surgeon), who died at Torquay on the 24th ult., was born in 1817, was educated at Harrow, and took his B.A. degree at Balliol College, Oxford, in 1839, and his Mastership of Arts in 1842. He was appointed to the chair of Chemistry at Oxford in 1855, and became President of the Chemical Society in 1859–60. The deceased was a Fellow of the Royal Society, and was created D.C.L. of his *alma mater* in 1872.

FROM the sixth annual report of the Syndicate appointed to superintend the examinations in State Medicine at Cambridge, it appears that at the October examination nine candidates presented themselves in Part 1 and eight in Part 2, five of whom passed in both. The small average number of candidates for this examination has suggested the necessity of some change in the arrangements under which it is conducted, or the raising of the fees.

MR. A. BREEDON WADE, M.R.C.S. Eng., formerly house-surgeon to the Royal South Hants Infirmary, and recently acting in that capacity until his successor should be appointed, was, on his leaving the institution, presented by the officers, nurses, and servants, with a handsome stationery cabinet and writing-desk, as a mark of the esteem in which Mr. Wade is held by the donors.

ANOTHER “bogus” institution has been exposed in America called the “New England University of Arts and Sciences.” The University was incorporated by the New Hampshire Legislature in 1875, but the charter was repealed in the following year. The diplomas were, it seems, chiefly medical, and cost from 100 to 145 dollars.

DR. BARTHOLOW, of the Jefferson College Medical School, has introduced a new feature in his method of teaching therapeutics. A laboratory has been fitted up in the College, and the students are taught practically how to compound and manipulate drugs.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Craven (Combined District).—The several reports of Dr. Frederick W. Barry on the sanitary districts (three rural and five urban) entering into the Craven combination, and sundry special reports on parts of these districts, have been published in one volume. We know no series of reports which more completely fulfil our notions of what the reports of a medical officer of health should be, and we would especially refer to the report on the Settle rural sanitary district as a model of the sort of report which should be aimed at in such districts. The greater number of the reports were noticed in THE LANCET at the time of their presentation to the sanitary authorities; others have been delayed in their appearance until their publication in the present volume.

The entire series of reports as here presented must prove invaluable to the combination of districts to which they relate, and will be found full of interest to medical officers of health and sanitary officers generally. We regret to say they will be the last reports that will be received from the pen of Dr. Barry as the medical officer of health of an English sanitary combination, at least, for some time to come. Dr. Barry has accepted the appointment of sanitary commissioner with the Government of Cyprus, and we are fain to congratulate that island on an acquisition which we most unwillingly have lost after just proving its value.

Rotherhithe.—The first annual report which Dr. Browning, as medical officer of health for the parish of St. Mary, Rotherhithe, has been called upon to make, and which only now sees the light towards the close of 1880, is for the year ending December, 1878. It is issued with the annual report of the Vestry for the year ending March 25th, 1879, but even when published in this association it is not easy to understand why its general distribution should have been so long delayed.

Dr. Browning introduces his report by a brief description of the sanitary condition of Rotherhithe in the past as compared with the Rotherhithe of the present. In 1856, he tells us, the various local governing bodies in the metropolis were first authorised to appoint “medical practitioners of skill and experience” to act as their advisers in matters of public health. Rotherhithe was then supposed to be one of the most insalubrious suburban districts. It was almost entirely unsewered, marshy, with a scanty water-supply, and that “so contaminated as to be usually refused even by horses from other parts of the town which had to bait while passing through it.” Further, it had within its boundaries fifteen miles length of open, fetid, stagnant ditches, serving as watercourses and cesspools. Its population of 15,000 was mostly packed into “a narrow river-side street, backed generally by blind alleys and courts, amidst which numerous offensive manufactories flourished unchecked, and where the various agues, fevers, and other communicable diseases could at any time be seen without protracted quest.” The average annual death-rate of the parish was then 30 per 1000 population, and the fever-rate 23 per 1000. There was no public recreation ground, no provision for systematic removal of nuisances, nor for isolation of infectious diseases. This was the state of things in 1856. How different now! Rotherhithe with its 33,000 inhabitants, its 5000 houses having foundations below Trinity high-water mark, and its two miles and a half of foreshore, we learn from Dr. Browning, can vie as to airiness, dry, gravelly subsoil, cleanliness, good drainage, water-supply, and sanitary improvement generally, with any workmen’s quarter in the metropolis. There are no open ditches, and malarious illness is unknown. Noisome trade factories exist only on two or three sites, which possess certain prescriptive rights. Finally, Rotherhithe possesses a public park which attracts visitors from all parts of South London; communicable disease, as a rule, visits its precincts more lightly than those of its neighbours, its annual death-rate for the last decade averaged only 18·6 per 1000 population, and its fever-rate 3·6 per 1000, so that while the district had doubled in numbers of inhabitants and in density per acre, the mortality had diminished by nearly one-half.

Such are the great results of twenty-three years' intelligent sanitary administration of Rotherhithe. Dr. Browning's report for 1878 proves that the results as affecting the health of the inhabitants are being steadily maintained, and that even a higher state of health than has yet been attained will probably be secured in the future.

Wolverhampton.—Mr. John Harry Love, the medical officer of health for Wolverhampton, in his report for the year ending September 30th, 1880, records the lowest number of deaths which have occurred during any year for the past eight years. Moreover, there had been no epidemic during the period to which his report refers, and there was a further reduction in the mortality from preventable disease. Yet, satisfactory as this may be, much, he observes, has to be done in the town from a hygienic point of view. The following remark on infantile mortality deserves quotation:—"Many assign as the different causes [of this mortality] errors of diet and delicacy of infants; doubtless these have their place in the list, but I am constrained to add that it may in the main be traced to the scourge of this country, *drunkenness*. For where do we find premature birth, marasmus, inanition, atrophy, diarrhoea, and convulsions most prevalent but in the wretched, squalid hovels of the drunkard, the dissipated, and the indolent?" Mr. Love assigns the improved health of Wolverhampton to the abolition of the old midden system, the adoption of the pan system of excrement disposal, the better water-supply, and the removal of many surface nuisances.

Bradford, Yorks.—The medical officer of health's (Mr. Butterfield's) report for the summer quarter shows a birth-rate equal to 31·7 per 1000 persons estimated to be living in the borough, as against 35·8 and 31·2 in the corresponding periods of 1878 and 1879; and a death-rate of 22·4, as against 22·3 and 16·8 in the two previous corresponding quarters. In a severe epidemic of scarlet fever, it is remarked, the fever hospital proved of great advantage, and greater willingness was shown by parents to send their sick children there.

THE METROPOLITAN ASYLUMS BOARD.

The report of the meeting of the Metropolitan Asylums Board on the 27th ult., shows in the most striking way the anomalous position in which that Board is placed with reference to the provision of hospital accommodation in London. A Poor-law body, it has thrust upon it the most important sanitary functions, and is still required to act on the strictest Poor-law lines. Moreover, the advice tendered to it by the Local Government Board is wholly based upon poor-law tradition and practice, and as completely purged of public-health considerations as if the Central Board had no public-health responsibilities. This determined maintenance by the Local Government Board of poor-law relations solely with the Metropolitan Asylums Board, virtually ignoring the general sanitary functions they must unavoidably perform, has been the cause of much inefficiency of action already, and is about to be the cause of further inefficiency of action in the near future. The Central Board, in its endeavours to bring the action of the Asylums Board into some sort of agreement with that of the sanitary authorities and the sanitary requirements of the metropolis, appears simply to succeed in worrying and irritating the latter Board, handling its leading-strings in a feeble and vacillating fashion, humiliating to a body of which puerility is the last thing to be predicated. Here we are at the beginning of another epidemic of small-pox, with the existing accommodation for the disease exhausted before the epidemic is well declared. Not only this, but it is proposed by the Asylums Board to rent the only sanitary hospital existing in the East of London, and so (with the approval of the Local Government Board) turn to folly the action of the one sanitary authority there—the Poplar, which had done its duty in providing hospital accommodation. The Local Government Board still fails to reconcile its public health and its poor-law functions, and as a consequence exposes both sorts of authorities to untold annoyances in their relations with it. We sympathise with the Metropolitan Asylums Board in its most anomalous position.

THE METROPOLITAN WATER-SUPPLY.

Colonel Bolton, R.E., the water examiner, reports for the month of October that the water in the Thames at the intakes of the several water companies was good from the 1st to the 6th October, when it became very bad, and remained so to the end of the month. The water of the river Lea was

generally bad throughout the month. Filtration, although carefully attended to by the companies, failed to free the Thames water from the effects of organic matter, principally arising from vegetation brought down by the very heavy floods which prevailed during the greater part of October. The remarks attached to the tabular statement given respecting each company appear, however, to indicate that the filtration was of better quality than is here implied. The water from the Lea, after filtration, seems to have been "generally clear."

Colonel Bolton is getting "bothered," we are glad to see, with the chemical analyses of waters, from several independent analysts, which he multiplies in his reports, and which, not being comparable with each other, are of very doubtful utility. He again urges that "a standard of quality" should be adopted, and directs attention to the intermediate fouling of water which is apt to occur in storage cisterns.

AN IMPORTANT AND SUCCESSFUL EXPERIMENT IN THE ISOLATION OF SCARLET FEVER BLURRED.

We regret to find that the most interesting experiment which has yet been made in England in the isolation of infectious disease has given rise to legal proceedings on the part of a medical man intimately connected with it. We refer to the experiment tried by Dr. Ashby, medical officer of health for Grantham and the neighbouring districts, of dealing with an outbreak of scarlet fever in that town during the summer of 1878, by means of isolating the patients in tents. He prevailed upon the local authorities to erect a tent hospital on the outskirts of the town, and induced parents to send their sick there. The experiment was most successful. Parents availed themselves of the tents largely (their early prejudice against them being readily overcome), the patients admitted to the tents did remarkably well, and the spread of the disease was unquestionably much curtailed. Altogether the example set was one which deserved to be copied, and showed with what readiness the spreading diseases of children may be dealt with by the exercise of energy and forethought. Unhappily, we now learn this unique experience is defaced by the fact of the medical officer who had charge of the hospital having to take legal proceedings against the local authorities to recover the money due to him for his attendance. We print the case as it now stands elsewhere.

Sir Richard Cross, in answer to a communication from the Local Rights Association respecting the Artisans and Labourers' Dwellings Improvement Acts, 1875, addressed to him when Home Secretary, attributes the present imperfect working of the Act in the metropolis to the administrative authorities rather than to the original legislation. Many of the defects in the working might be remedied, he believes, by more cordial co-operation between the vestries and the Metropolitan Board of Works.

It is currently reported that the local authority of Maidstone has ingeniously contrived to produce two cases of typhoid fever in the town at a cost of £50,000—in other words, that the new system of sewerage it has constructed at this cost has, through the foul air coming from the ventilation-shafts of the sewers, produced this result. We are to infer that before the sewerage was completed typhoid fever was unknown in the town.

Bridlington Quay appears to have got into difficulties about a new system of sewerage, and discontented inhabitants are making known their grievances in the local press. The Local Government Board has even been appealed to, but it has replied to the complainants that the question at issue is one in which it cannot interfere, and must be settled between the local authority and the citizens themselves.

The Sanitary Committee of St. Saviour's, Southwark, have agreed to the presentation of a memorial to the Home Secretary praying that a Bill may be introduced into Parliament requiring the local medical officer of health, in all cases where no certificate of the cause of death has been given by a legally qualified medical man, or no inquest has been held, himself to give a certificate.

Although Birmingham possesses five mortuaries it is complained that they are little used, the people displaying great antipathy to the sending of corpses there.

An outbreak of fever is reported from Southport, said to be dependent upon the conveyance of infection through a milk supply. The milk was derived from a farm in the Ormskirk rural sanitary district, and the Rural Sanitary Authority is co-operating heartily with the Southport Corporation to put a stop to further mischief from this source.

Notice has been given that a Bill will be submitted to Parliament during the next session which will contain provisions for enacting a Water-Trust for the metropolis, and for giving to this Trust ample powers for entering into arrangements with the existing Water Companies for the acquirement of their works and for obtaining water from other sources.

The Native Guano Company, we learn, has been engaged in making some experiments at Lincoln, with the object of abating a nuisance arising from the sewage of the County Hospital. It is reported that the experiments have been successful, and that by the adoption of their process it will be possible to deal with the sewage without creating a nuisance.

We learn from the medical officer of health of the Brown-hill's Urban Sanitary District, Staffordshire, Mr. David Edgar Harris, that seven deaths only occurred in the district during the month, representing a death-rate of 7.7 per 1000 inhabitants per annum. This is, indeed, a singularly low rate of mortality for a large mining district.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality showed a slight increase last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4874 births and 3175 deaths were registered last week. The births were 311, and the deaths 100, below the average weekly numbers during 1879. The deaths, however, showed an increase of 131 upon the low number returned in the previous week; and the annual death-rate per 1000, which had been equal to 22.8 and 21.2 in the two preceding weeks, rose again last week to 22.1. The lowest death-rates in the twenty towns last week were 16.7 in Bradford, 16.7 in Portsmouth, 18.0 in Brighton, 18.5 in Leeds, and 18.9 in Birmingham. The rates in the other towns ranged upwards to 25.3 in Salford, 25.7 in Plymouth, 25.9 in Sunderland, 26.1 in Nottingham, 28.7 in Liverpool, and 29.5 in Wolverhampton. During the first eight weeks of the current quarter the death-rate in these twenty towns averaged 22.1 per 1000, against 22.0 in the corresponding periods of the four years 1876-9.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 474 and 367 in the two preceding weeks, rose again to 405 last week; they included 162 from scarlet fever, 62 from measles, and 55 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2.8 per 1000 in the twenty towns, and ranged from 0.7 and 1.1 in Plymouth and Birmingham, to 5.6 and 7.6 in Salford and Sunderland. The fatal cases of scarlet fever, which had been 163 and 138 in the two previous weeks, rose again to 162 last week, and showed the largest proportional fatality in Sunderland and Nottingham. Measles was most fatal in Salford and Leicester. The highest death-rates from enteric fever occurred in Salford, Sunderland, Portsmouth, and Liverpool. The 17 deaths from diphtheria in the twenty towns included 11 in London and 3 in Portsmouth. Small-pox caused 21 more deaths in London and its outer ring of suburban districts; but no death from this disease was recorded in any of the nineteen provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased in the four preceding weeks from 77 to 182, further rose last week to 210, a higher number than has been under treatment in these hospitals since the end of July last. The number of new cases of small-pox admitted to these hospitals, which had been 31 and 99 in the two preceding weeks, were 57 last week. The Highgate Small-pox Hospital contained 19 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 421 and 332 in the two preceding

weeks, rose again to 367 last week, but were no less than 116 below the corrected weekly average; 221 resulted from bronchitis, and 104 from pneumonia. The annual death-rate from lung diseases was equal to 5.2 per 1000 in London, and 7.1 in Liverpool.

In the twenty towns last week 65 deaths were registered without the production of the certificate of a registered practitioner or the holding of an inquest; these were equal to 2.0 per cent. of the total deaths. The proportion of uncertified causes of death did not exceed 1.2 per cent. in London, whereas it averaged 2.8 per cent. in the nineteen provincial towns. No uncertified deaths were registered in Brighton, Portsmouth, or Norwich, while the largest proportions occurred in Sunderland, Wolverhampton, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week was equal to 24.7 per 1000, against 23.8 and 20.9 in the two preceding weeks, and was 2.6 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 17.5 and 21.1 in Perth and Dundee, to 32.1 and 38.2 in Greenock and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 125 and 95 in the two previous weeks, rose again to 112 last week; they included 37 from scarlet fever, 20 from diarrhoea, 17 from whooping-cough, 14 from measles, 14 from diphtheria, 10 from fever, and not one from small-pox. The annual death-rate from these seven diseases averaged 4.5 per 1000 in the eight towns, and exceeded by 1.7 the average rate from the same diseases in the twenty English towns. In the eight Scotch towns the zymotic death-rate last week ranged from 0.5 and 1.3 in Aberdeen and Dundee, to 7.4 and 8.0 in Paisley and Leith. The fatal cases of scarlet fever in the eight towns, which had been 53 and 45 in the two preceding weeks, further declined last week to 37, of which 18 occurred in Edinburgh, 8 in Leith, and 11 in Glasgow. The 20 deaths from diarrhoea showed a marked excess for the time of year, and included 8 in Glasgow and 4 in Paisley. The deaths from whooping-cough, measles, and diphtheria also showed a considerable increase upon recent weekly numbers. This increase was most marked in Glasgow, where 12 of the 14 fatal cases of diphtheria were recorded. The deaths referred to fever, which had been 20, 14, and 12 in the three preceding weeks, further declined to 10 last week, of which 4 occurred in Glasgow, 3 in Edinburgh, 2 in Greenock, and one in Paisley. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 154 and 137 in the two preceding weeks, rose to 166 last week. The annual death-rate from these lung diseases was equal to 6.7 per 1000 last week in the eight Scotch towns, against 4.7 in London; the highest death-rates last week from these diseases in the Scotch towns occurred in Glasgow and Greenock.

HEALTH OF DUBLIN.

The death-rate in Dublin showed a marked increase again last week. The annual rate of mortality from all causes in the city, which had been equal to 39.6 and 33.3 in the two preceding weeks, rose again last week to 37.8. During the past eight weeks of the current quarter the death-rate in the city has averaged 34.8 per 1000, against 21.4 in London and 22.4 in Edinburgh. The 228 deaths in Dublin last week exceeded the number in the previous week by 27, and included 42, or 18 per cent., which were referred to the seven principal zymotic diseases, showing an increase of 17 upon those returned in the previous week; 17 resulted from fever (including typhus, enteric, and simple), 11 from scarlet fever, 6 from whooping-cough, 4 from measles, 2 from diarrhoea, 2 from small-pox, and not one from diphtheria. The annual death-rate from these zymotic diseases was equal to 7.0 per 1000 in Dublin last week, against 2.8 in London and 5.7 in Edinburgh. The deaths referred to fever, which had been 7 and 10 in the two previous weeks, further rose to 17 last week; the annual death-rate from this cause has averaged 1.4 per 1000 in the city during the past eight weeks, against 1.1, 1.5, and 1.0 in the first three quarters of the year. Fever has been since the beginning of the year exceptionally fatal in Dublin. The 11 deaths from scarlet fever in the city last

week showed a considerable increase upon the numbers in the two previous weeks. The fatal cases of measles and of whooping-cough were also more numerous. The deaths of infants in the city showed a further decline last week, whereas those of elderly persons exceeded the number returned in any week since the middle of February last.

AUSTRALIAN VITAL STATISTICS.

The colony of Victoria has recently issued its Statistical Register for the year 1879, which has been compiled by the Government Statist, Mr. H. H. Hayter. As regards tabular arrangement and fulness of detail these statistics leave little to be desired, and it is only to be regretted that want of faith in the trustworthiness of the materials from which they are constructed should to so large an extent destroy the interest which would otherwise attach to their publication. This Statistical Register consists of a series of tables, which, as we have said, are excellently arranged, but they are unaccompanied by any explanatory remarks, which might throw light upon some of the figures that undoubtedly require explanation. The mean population of the colony of Victoria in 1879 is estimated at 888,500; the annual rate of marriages, births, and deaths, per 1000 of the population, during the year is given as 5.6, 30.2, and 13.6 respectively. With regard to the rate of marriages, we find by doubling it that the rate of persons married in the colony in 1879 was 11.2 per 1000, against 14.4 in England and Wales; this figure would not seem suspiciously low, except for two facts that throw doubt upon its accuracy. In the first place, the marriage rate has steadily declined in the colony during the past eleven years from 13.6 in 1869, to 11.2 in 1879; and secondly, the marriage rate in about half of the entire population classed as extra-urban is returned at but 4.6 per 1000. We certainly doubt that in a population constituted as is that of Victoria, the marriage rate would steadily decline during a period of eleven years; neither is it probable that among the nearly half a million of persons living in the extra-urban districts the marriages should scarcely exceed the rate of 2 per 1000 of the population. We are forced to take exception on very similar grounds to the Birth and Death statistics; the figures show an almost similar decline in the birth-rate and death-rate of the colony during the eleven years 1869-79. The recorded birth-rate, which is given as 37.4 and 38.3 in 1869 and 1870, is said to have declined to 30.6 and 30.2 in 1878 and 1879. So with the death-rate, it has rapidly and steadily declined from 18.8 in 1875 to 13.6 in 1879. The death-rate is suspiciously low throughout the eleven years, and added to this we find that the urban rate in 1879 did not exceed 18.7, while in the extra-urban population, of nearly 430,000, the rate is given at the almost incredibly low figure of 8.1 per 1000. Bearing in mind the remarkable, and altogether unusual, steady decline in the rates of marriages, births, and deaths during the eleven years under notice, it appears impossible to avoid the conclusion that the Government Statist has considerably over-estimated the population of the colony; he has unfortunately omitted to state the method which has been used in arriving at the estimate, and there is, therefore, no possibility of judging of the trustworthiness of the estimate, except through the calculated rates. There is only one other way that suggests itself for explaining the low and declining rates of marriages, births, and deaths in Victoria in recent years; this is, defective registration of the marriage, birth, and death facts, which in the more sparsely populated portions of the colony is probably unavoidable. It may readily be believed that the age constitution of the Victoria population residing in the extra-urban districts would render it liable to a low death-rate, but it is difficult to believe that if all the deaths were registered, and the numbers of the population were more accurately known, the annual death-rate would be found to be so low as 8.1 per 1000.

HEALTH OF SWITZERLAND.

The Federal Statistical Bureau has issued its quarterly summary of vital statistics relating to the three months ending 30th September last. These returns deal with an aggregate population estimated in the middle of this year at nearly half a million of persons living in the twenty Swiss towns, with upwards of 7000 inhabitants. It appears that during the three months ending September last the annual death-rate in the aggregate population of these

twenty towns averaged 22.8 per 1000, showing a further decline from the rates in the four preceding corresponding quarters, in which they had steadily decreased from 25.0 to 23.6. Among the several towns the annual rate in the quarter ranged from 12.0 and 12.9 in Geneva and Locle, to 25.9 in Basle, 27.2 in Herisau, 27.7 in St. Gallen, and 29.2 in Einsiedeln. No less than 710 deaths in the twenty towns during the three months were due to the seven principal zymotic diseases, being equal to 27 per cent. of the deaths from all causes; in the main, however, this zymotic fatality showed a decline from that which prevailed in recent summer quarters. Only three fatal cases of small-pox occurred during the quarter, two in Chaux-de-Fonds, and one in Zurich. The deaths from typhus and enteric fever were more numerous than in either of the two preceding summer quarters, owing to epidemic fatality in Basle and in the district around Zurich, where scarlet fever and diphtheria were also fatally prevalent. Although fever was more fatal last quarter than in the summer quarters of 1878 or 1879, it was very considerably less fatal than in the corresponding periods of 1876 and 1877. It is worthy of note that, with one or two exceptions, all the causes of death in the quarter were duly certified and attested.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE SOURCE OF TYPHOID FEVER: AN INSTRUCTIVE CASE.

The Vestry of Lambeth and its medical officer of health have been much perturbed by a certificate given by Sir W. Jenner and Mr. Dee Shapland to the effect that a fatal case of typhoid fever that had occurred in the district, and had been attended by them, was probably caused by the imperfectly-arranged drainage of the house in which the patient lived, and implying that the local sanitary authority had been neglectful. Dr. Archer Farr has published a pamphlet purporting to show that Sir W. Jenner and Mr. Dee Shapland had been wholly misinformed as to the drainage arrangements of the house in question; that the local authority had been far from unmindful of its duties in the house when there had been occasion to exercise them; and that in all probability the fever had been contracted at the patient's place of business in the City, where the drainage arrangements appear to have been as bad as could well be, where the medical officer of health writes of the premises as having "long been a source of trouble and anxiety" to him, and where a brother of the principal contracted an illness, presumably from this source, about the same time when Mr. Dee Shapland's patient sickened, and which illness, at the time of Dr. Archer Farr writing his explanatory pamphlet, was suspected to be typhoid fever.

EXCESSIVE MORTALITY AMONG SOUTH-SEA ISLANDERS IN QUEENSLAND.

A report has been published by the Legislative Assembly of Queensland on an excessive mortality amongst the South-Sea Islanders engaged on certain sugar plantations in Maryborough. The reporters were Dr. John Thomson and Mr. C. J. Hill-Wray, and they disclose a very unsatisfactory state of things among the labourers in the plantation, who are recruited from the South-Sea Islands. It would appear that there is no proper security that the recruits brought over are of sufficient maturity to undergo the heavy labours of a plantation; and that the hours of work are too protracted, the accommodation provided too often ill-considered, the water-supply bad and wanting during the period of work, and the diet at times insufficient both in quantity and quality. It is not surprising then to find fatal sickness prevalent among the Polynesians, and that "dysentery" is a prevalent disease among them—a term, however, which, not dictated by a medical attendant, appears to include pulmonary consumption accompanied by diarrhoea, enteric fever, and, as the reporters had an opportunity of observing, even scurvy. Poor feeding, bad water, overwork, and the absence of proper care when sick, were, in the opinion of the reporters, the causes of the excessive mortality which had been brought to the notice of the Colonial Government, and there is little likelihood of these causes being removed until the Legislative Assembly has given more efficient protection than it has hitherto done to the unfortunate islanders.

We regret to see, from the *Daily Picayune* (New Orleans), that the State Board of Health of Louisiana and the National Board of Health have disagreed about a question of quarantine. We trust that the disagreement arises rather from a misapprehension of facts than from any dissent from the general policy of the National Board.

It is proposed to give the inhabitants of Painswick, near Stroud, a free water-supply, using for the purpose of procuring it a bequest of £5000 left to the town by Mr. F. Gyde.

THE SERVICES.

THE ROYAL MILITARY ACADEMY, WOOLWICH.

Surgeon-Major G. J. H. Evatt, M.D., has been appointed to succeed Surgeon-Major Roberts as Medical Officer to the Royal Military Academy, Woolwich. Dr. Evatt has recently arrived from Afghanistan, where he had been in charge of one of the field hospitals with the Cabul Field Force for the last two years.

Brigade-Surgeon J. Ekin, M.D., is appointed to the administrative charge of the Allahabad Division, with the officiating rank of Deputy Surgeon-General.

Brigade-Surgeon J. Hanbury is appointed to the Rawal Pindi Division, with the officiating rank of Deputy Surgeon-General, *vice* Deputy Surgeon-General A. Smith, C.B., on sick leave.

Sickness has considerably increased in the Candahar Force since the inactivity and reaction after the siege and late battle with Ayoub Khan. By the last advices, the European Army had nine per cent. in hospital, and the native troops eleven. The coming cold weather will, we trust, considerably improve the health of the garrison.

MILITIA MEDICAL DEPARTMENT.—Surgeon-Major William Batley, Royal Sussex Militia, resigns his commission; also is permitted to retain his rank, and to continue to wear his uniform on retirement.

ADMIRALTY.—Staff-Surgeon W. B. Fletcher has been appointed to Devonport Dockyard; Staff-Surgeon J. L. Sweetman to the *Fawn*; Staff-Surgeon C. J. Fennel to the *Téméraire*, when recommissioned; Staff-Surgeon W. P. L. Boyle to the *Dotterel*, when recommissioned; Staff-Surgeon Valentine Duke to the *Champion*, when recommissioned; Surgeon James Porter to the *Orontes*; Surgeon John Tyndall to the Haulbowline Hospital; Surgeon H. M. Ellis to the Royal Marine Artillery Division; Surgeon James Simms to the *Excellent*; Surgeon H. E. F. Cross to the *Téméraire*.

Correspondence.

"Audi alteram partem."

ON MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—The great question of medical education, at all times an urgent one, has been of late pressed forward with more vehemence than ever. And no wonder. For after all that has been said and done, a solution of the difficulty which can be, in any sense, called satisfactory seems as far off now as when many years ago the conjoint scheme was first proposed. I would suggest that our failure hitherto has been due to the fact that we have dealt with the evil in the wrong way. We have from the first been attempting to prescribe for the symptoms without previously ascertaining the cause of the mischief. Witness the lengthened discussions of the subject, and especially what was said in some of the sections at the recent meeting of the British Medical Association at Cambridge. Speak to a teacher of medicine, and he tells you how inadequately the study of medicine is carried on. Speak to a teacher of surgery, and he tells you the study of surgery is strangely neglected. The obstetric physician bewails the indifference shown to the study of obstetric medicine. The psychologist is shocked that so little heed is given to his side. Then all the teachers

of natural science with one voice declare that it is idle to expect of students, in the circumstances in which they are at present placed, anything like a genuine knowledge of anatomy, physiology, or chemistry. What is to be done? Reduce in some degree the amount of knowledge required of some of the subjects, so that more attention may be given to others? But only let some one propose to remove from the curriculum of study any single subject, or to reduce the proportion in which it challenges the attention of the student, and at once an army of champions arises not only with irresistible arguments against obliteration, or even reduction, but with many very forcible ones to show why the study of that particular subject should be extended. There appears to be one point only on which all teachers are agreed; eager criticism, always more or less unfavourable, of examinations and examiners, while examiners, in their turn, deplore the shortcoming of teachers and the way in which they waste the time of the student. The student, himself the victim, of course, heartily agrees with the criticism on both sides. Now, what does all this mean? Surely there must be something wrong somewhere. I, for one, think there is something wrong everywhere, and that it is this—*want of time*. The student has not time enough for the work which ought to be done. Only think for a few moments of what is required of a student during the period at which it is arranged he shall be at a hospital. Think of the few months allowed for anatomy and physiology, for medicine and surgery. Is it practicable for average human intelligence, or even for extraordinary ability, thus in any way to do justice to the several subjects of study? By degrees the evil has arisen, and so it has come to be endured. Surely, if we were placed at once face to face with the existing order of things, we should think it too absurd for consideration. Let us try to contrast the demand made upon a student at the present day with what it was a quarter or half a century or so since, and compare this with the additional amount of time at a hospital given to him within the same period. Surely, then, one may begin to understand how this supreme difficulty has arisen, and to anticipate, in the present state of affairs, its inevitable increase. Obviously, therefore, the first step forward to take in the way of education is to lengthen the period of the students' work at the hospital. I should say at once that, in my opinion, seven years is not an hour too long. But how impracticable! Why? I suppose chiefly or solely on account of the additional expense. Well, I cannot now, in this letter, enter into this objection further than to declare that it seems to me to have little magnitude in proportion to the evil which exists, and for which I believe it to be the sole remedy. I cannot help setting forth this view, although, of course, I have no expectation of its acceptance, and, failing its adoption, I must say, after some experience in the matter, that rather than consent to the existing state of things I would reduce within far narrower limits the area of studies, insisting, however, at the same time, that what was actually required should be thoroughly learnt. For I am convinced that the system of cramming, which now passes current for knowledge, is not only, in chief part, useless in practice for any technical purpose, but that it is positively mischievous, in no slight degree demoralising, to the student. In many it is altogether, and in all it is in some degree, opposed to honest study, to real genuine knowledge, to thoroughness of purpose, and devotion to truth. For it is, in its very nature, essentially false.

I am, Sir, yours, &c.,

Nov. 30th, 1880.

Wm. S. SAVORY.

ON WATCHING THE PULSE DURING THE ADMINISTRATION OF CHLOROFORM.

To the Editor of THE LANCET.

SIR,—In reading the article on the Administration of Anæsthetics by Dr. Saundby in THE LANCET of Nov. 20th, I was surprised to find that he says with reference to the administration of chloroform, "The pulse may be disregarded, as it gives no timely warning of approaching danger." As this is in direct opposition to my own experience, I shall be glad if you will permit me to give my reasons for saying that the careful watching of the pulse during the inhalation of chloroform is of the utmost importance.

During the present year I have given anæsthetics at

St. Bartholomew's Hospital 1420 times, and of these chloroform 572 times; and in three of these cases I have had reason to be thankful that I carefully watched the pulse during the administration. I believe that had I not done so I should have lost the patients.

Case No. 7673 was a woman, aged forty, under the care of Mr. Power. The operation was iridectomy of the left eye and abscission of the right. The patient took chloroform well until the end of the operation, when the pulse failed suddenly, the respiration continuing. I gave directions for the feet to be raised (Nélaton's method), and I had drawn out the tongue and was ready to commence artificial respiration when the breathing, as I had anticipated, failed also. After three or four thorough compressions of the chest the patient gasped, but did not breathe properly for some minutes, during which time artificial respiration was maintained.

Case No. 8688 was a woman, aged seventy-six, bronchitic and asthmatic. Removal of large tumour of the breast, under the care of Mr. Thos. Smith. During the operation the pulse became weak and irregular, and then stopped, the respiration continuing. I treated her in the same way as the case above. The pulse returned and gradually improved from the time the legs were raised. The operation was completed without interruption. The respiration did not entirely cease.

Case No. 8702 was a man, aged thirty-four. The operation was for the removal of a small tumour from the scalp, and was performed by Mr. Lockwood, house-surgeon. During the operation the pulse became weak and irregular, and then stopped. Knowing what to expect, the same treatment was adopted. Respiration also now stopped, and artificial respiration was immediately performed while the patient was supported by the legs. A minute and a half elapsed before the respiration returned.

Now, in each of these cases I maintain that the pulse gave timely warning of approaching danger. No looker-on, how carefully soever he may have watched the respiration, would have suspected what was about to happen before I had given directions for the patient's legs to be raised, and had in my hand a pair of dressing-forceps ready to draw out the tongue.

It may be argued that to have three cases of the kind quoted in 600 administrations is a very unusual occurrence. And with this I entirely agree. Out of the total number of cases (nearly 9000) in which I have administered anaesthetics of one sort or another, I do not think more than half a dozen cases of this kind have occurred. To have three cases, therefore, in a year, represents merely the curious manner in which exceptional cases occur together; the last two happened within a few days of each other. It may be said, too, that in point of time a few seconds only were gained in each of these cases. But if by watching the pulse a few seconds can be gained in the application of restorative means to one case in *ten thousand*, it is in my mind a sufficient reason for most carefully watching the pulse in each and every case.

I am, Sir, yours obediently,

JOSEPH MILLS,

Administrator of Anesthetics to St. Bartholomew's Hospital.

Nov. 27th, 1880.

M. PASTEUR'S EXPERIMENTS WITH CHICKEN-CHOLERA.

To the Editor of THE LANCET.

SIR,—The researches of M. Pasteur, published in your columns on Nov. 6th, must claim the careful consideration of all who are interested in the present state of preventive medicine and sanitary science—and who are not? Prof. Huxley had expressed an opinion that these experiments would be the means of placing vaccination upon a scientific basis, but this opinion does not seem to be justified.

M. Pasteur's chief points are—that chicken-cholera is a virulent disease, rarely recurrent, due to a microscopic parasite, capable of cultivation, and also of *attenuation* outside the body; the attenuated virus, when retro-inoculated, producing a mild disease, and securing from subsequent attack. A reference to vaccination in the paper suggests an analogy between it and the attenuated virus, but M. Pasteur is too scientific a man to insist this relation. "The difference

is great," he says, "in some respects between the two classes of facts, and it may be well to remark that as regards our knowledge and our deductions the advantage is with the study of fowl's cholera; the relations between variola and vaccine are still a matter of controversy." The experiences of the Lyons commission, conducted by M. Chauveau, were, no doubt, in M. Pasteur's mind when he hesitated to draw an analogy between small-pox and vaccinia and chicken-cholera and its attenuated derivative; this commission and its admirable report, entitled "*Vaccine et Variole, nouvelle étude expérimentale sur la question de l'identité de ces deux affections*," have been too much ignored, at least in this country. After careful and patient investigation the commissioners reported that, "Notwithstanding the apparent resemblances which, both in animals and man, exist between variola and vaccinia, these two diseases are none the less perfectly independent, and cannot be transformed the one into the other." As Dr. Cameron has tersely put it, "You can no more make small-pox into cow-pock than by stunting an oak tree you can make it a gooseberry bush."

But to return to M. Pasteur's paper, and to the most important question raised in it, By what means is the cholera virus attenuated and destroyed? The answer is clear, logical, and conclusive: "It is the oxygen of the air which weakens or extinguishes the virulence." Tubes of virus hermetically sealed retained their virulence for months; tubes of virus exposed to pure air gradually and progressively, with almost mathematical precision, lost their virulence, and became innocuous. The microscopic parasite was dead! Here was the presence of the cause (the oxygen) followed by the presence of the effect (the death of the parasite, and extinction of the virulence of the poison), the absence of the cause followed by the absence of the effect; and the greater the amount of the cause the greater was the effect. What more logical? M. Pasteur wisely asks, "May we not here be in the possession of a principle? It may be hoped the inherent action of atmospheric oxygen, a natural force which is everywhere present, will be found efficacious in other virus. May we not presume henceforth that it is to this influence we may attribute the limitation of great epidemics?" Without accepting unreservedly this plausible hypothesis, it is curious to see how readily it offers an explanation of many scattered facts with which we have become acquainted—e.g., the efficacy of isolation and the limitability of infection, the utility of oxidising disinfectants, the salubrity of the country and the morbidity of the town, the success of the cool or open-air treatment of certain diseases, the decline of zymotic disease before the progress of sanitation, and many others. The theory harmonises these facts, and supplies a reason for what was before empirical only, though none the less true.

M. Pasteur's conclusions receive additional support from experiments made by Professor Thiersch and Dr. Burdon Sanderson on mice with the poison of human cholera. It was found that the poison intensified up to the third day, and then attenuated under exposure to air or cold.

What, then, are the inferences to be drawn from these facts? Do they warrant the inoculation of all persons with the attenuated viruses of all zymotic diseases with a view to prophylaxis? Do they not rather establish a stronger plea for extended sanitation, for the means of fighting diseases outside our bodies and not within them, for making our hygiene so good that prophylactics and antiseptics shall be superfluous?

I am, Sir, yours faithfully,

W. J. COLLINS, B.Sc., M.R.C.S.

St. Bartholomew's Hospital, Nov. 16th, 1880.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—I beg leave to inform your readers, if you will kindly print this, that a committee is formed in Southwark for the reform of the government of Guy's Hospital. The first step will be to increase the committee, and then immediately to hold a public meeting at the Bridge House Hotel. Mr. Alexander Hawkins, jun., member of the School Board, is the honorary secretary. I hope members of our profession, favourable to this movement, will send their names for this committee, directed to Mr. Hawkins, Vestry Hall, Borough-road, Southwark.

I am, Sir, your obedient servant,

W. RENDLE, F.R.C.S.

IRELAND.

(From our own Correspondent.)

THE name of Dr. Lyons, M.P. for Dublin, has been mentioned as a probable successor to the late Dr. Alfred Hudson on the General Medical Council.

The entries of students at the various medical schools in Dublin ceased on Nov. 22nd, and from the returns received from those institutions, I learn that for the present session a total of 848 students have been enrolled. Of the five medical schools the Ledwich, as usual, has the highest number—viz., 230; followed by Trinity College, 192; next the College of Surgeons, 183; then the Carmichael, 149; and lastly the Catholic University, with 94. All these institutions exhibit an increase over the session 1879–80—a fact which may be partly attributed to the fifty-eight students who were attached to Steevens's Hospital Medical School last year having been dispersed, owing to the closing of that school of medicine.

The first meeting of the forty-third annual session of the Dublin Obstetrical Society for the present year was held in the College of Physicians on the 27th ult. Sir Edward Burrows Sinclair, the outgoing President, delivered a short address, thanking the members for the honour they had conferred upon him in electing him their president, the duties appertaining to which he had endeavoured to discharge to the best of his ability. He congratulated those present upon the progress the Society was making in Dublin, and mentioned the fact that the Presidents of both the College of Surgeons and the College of Physicians were members of that Society. Allusion was then made to the honour Her Majesty had conferred upon him—the honour of knighthood—a distinction which he greatly prized as coming direct from the Sovereign herself. It was an honour conferred upon him because of the efforts he had made in having trained upwards of four hundred skilled nurses at Sir Patrick Dun's Hospital as midwives for the wives of soldiers; and he was happy to say one of those trained nurses would at present be found at almost every station of the British army, whether at home or abroad. Sir Edward concluded by referring to the lamented death of Dr. Alfred Hudson. Dr. McClintock, President of the College of Surgeons, moved the thanks of the Society to the outgoing president, on whom a high distinction had recently been conferred—bestowed on only two previous occasions, as far as he was able to ascertain, on men eminent in obstetric science. Dr. George Johnston, President of the College of Physicians, seconded the motion, which was cordially adopted.

The Board of Management of the Belfast Royal Hospital, in their recent report for the year ending 31st of last August, regret that they had to apply to the Corporation for authority to expend a large proportion of the donations and bequests to meet the current expenditure of the institution, and clear off the old outstanding debts. To carry on the hospital, however, in full efficiency they had no other course open to them, the fixed annual income of the charity not being sufficient for the requirements of the institution as at present worked, and recourse was had to capital sums, or the usefulness of the charity must have been materially reduced. During the year 1609 persons were treated in the wards and 14,867 patients attended to at the extern department.

Dr. Mapother, President of the Statistical and Social Inquiry Society of Ireland, delivered the inaugural address last Tuesday.

Dr. Faussett, late medical officer of Clontarf dispensary district, has been granted a retiring allowance of £106 6s. 3d. per annum by the Guardians of the North Dublin Union, the Board having rescinded their former grant of £50 yearly. This tardy recognition of Dr. Faussett's services has come too late, as that gentleman died last Monday, the 29th ult.

The returns for the September quarter show a decrease in the population of Dublin of 11,375, caused by emigration. The poor-law returns furnished by the Local Government Board exhibit a considerable increase in the number of persons receiving relief, as compared with the corresponding quarter of 1879.

Dublin, Nov. 30th, 1880.

PARIS.

(From our own Correspondent.)

A SOCIETY has recently been founded in Paris for the propagation of cremation, which is at present illegal in France, and the names of a number of medical authorities and municipal councillors figure amongst the general committee. The object of the society is twofold. First, to agitate for legislative measures in favour of cremation; secondly, to encourage scientific research as to the best means of putting it into practice. All those who are in favour of cremation, and who will engage to exert themselves actively in the furtherance of the cause, are invited to join, the number of members being unlimited, and as the annual subscription is small a great many adhesions may be expected. When the first object is attained, and cremation has become legal, the society will change its name to that of Société Française de Crémation, and will devote itself peaceably to the construction of crematoria and cineraria, and to the gratuitous incineration of defunct members.

The *Progrès Médical* contains an article by Dr. Laudouzy on a means of arresting the cough of phthisical patients, at any rate for a sufficient length of time to enable the hospital physician to perform auscultation. This is the hypodermic injection of distilled water, or, better still, a weak solution of cherry-laurel water. In order that the knowledge of the remedy used shall not be a bar to its efficacy, Dr. Laudouzy prescribes it under the name of binoxide of hydrogen. The injection should be made as near the pulmonary lesion as possible.

At the Academy of Medicine the greater part of the last three sittings has been occupied by Dr. Maurice Raynaud, who communicated his researches on the treatment of cerebral rheumatism by cold baths. The method seems to have been as successful in France as it has been in England.

PYRMONT AND OEYNHAUSEN.

*(From our Roving Correspondent.)**(Concluded from p. 833.)*

NOT much space need be devoted to a description of Oeynhausen. The natural beauties of the locality cannot in any way compete with those of hundreds of other health resorts, and its main attraction is its mineral water. I shall therefore give only a few words to the locality, and shall discuss the merits of the water at some length. Oeynhausen is a small town in close connexion with the neighbouring village of Rehme, and the words Rehme and Oeynhausen, either separately or in combination, are used almost indifferently to denote the locality. It has a station on the direct line from Cologne to Hanover, and is 154 miles from the former and fifty miles from the latter city. In the village of Rehme are large salt-works belonging to the Prussian Government, which date from about the year 1750. In the year 1830 it was thought advisable to increase the quantity of salt water available for the salt-works by sinking an artesian well, and the necessary operations were completed after sixteen years of labour by an engineer named Oeynhausen, who sunk his shafts to a depth of 2200 feet, and ultimately obtained a continuous flow of salt water, amounting to sixty cubic feet in the minute. The water was first used for bathing purposes by the workpeople engaged in the boring operations and by the peasantry of the district, and the first bath erected was in 1839–40. In 1848 the commencement of the present bathing establishment was made, and it was named after the distinguished engineer (Oeynhausen) who conducted the works. At present there are two large bathing establishments and a vapour bath, and the annual number of guests amounts to between three and four thousand. The bathing establishment is surrounded by a large park, laid out upon the sandy soil, and the usual amusements (music, reading-room, concert-room, &c.) are provided for the visitors. The neighbourhood is pretty enough, but not likely to attract mere pleasure-seekers. The huge walls of faggots constructed for the purposes of the salt works and over which salt-water is

continually trickling, are said to ozonise the air in proximity with them and to fill it with saline particles, and certain classes of invalids are recommended to haunt the neighbourhood of these moist faggot-piles for the purpose of inhaling the so-called *Gradier-luft*.

Without its salt-water Oeynhausen could have no claim to be considered as a health-resort, and I will, therefore, refer somewhat fully to this water and its effects. The water contains about 4½ per cent. of solids, of which 3½ per cent. are chlorides (chiefly sodium chloride). It has a specific gravity of 1030, a natural temperature of about 90° F., and each litre contains about 750 cubic centimetres of free carbonic acid. Warmth, salt, and free carbonic acid are, therefore, the three factors which may be credited with special therapeutic effects.

Julius Braun, the author of the well-known work on Baths and Mineral Waters, was physician at Oeynhausen for many years, and his explanation of the effect of salt (or Sool) baths may be accepted. There is no evidence that either the salt or the carbonic acid undergoes any absorption, and the effect of the bath is entirely due to the irritation by the water of the terminations of the cutaneous nerves. Braun asserts that the effect produced by a strong salt bath at a temperature of 95° F. is equal, both as regards objective phenomena and subjective symptoms, to a pure water bath at 100° F. The water of Oeynhausen has a natural temperature fit for bathing, and thus having neither to be cooled nor heated before use the contained carbonic acid is not suffered to escape during a long exposure or expelled by artificial heat. The water comes frothing into the bath tub, and there suffers its first loss of gas. On being placed in one of these natural baths the patient experiences a slight sense of chill, but this in the course of a minute or so gives way to a strong reaction, as evidenced by a feeling of warmth and comfort and a glowing skin. The temperature of the body sinks during the bath, but the patient nevertheless experiences (it is said) the comfort and quiet of a warm bath. It is essential that the bath be not too hot, or else the stimulation becomes too violent. It is necessary also that the water be not agitated, so that the escape of carbonic acid be not hastened, and the pernicious effects of its inhalation by the patient be engendered. The effect of such a bath is to strongly stimulate the skin, and through it the central nervous system; blood movement is increased, tissue change is hastened, and the whole system is roused to an unusual state of activity. These baths are said to be of particular service to weakly convalescents unable to undergo the fatigue of sea-bathing, or to take active exercise, in order to produce reaction. By the triple irritation of warmth, salt, and carbonic acid, reaction is produced with a maximum facility. In cases of gout and rheumatism, where the joint affection has not become too chronic, and in cases of muscular rheumatism, Oeynhausen has some reputation, but it is for scrofula in all its manifestations that these baths are most employed. "Skin culture" is much insisted on in Germany as a means of treating scrofula, and the baths of Oeynhausen are naturally popular as skin stimulants. All forms of paraplegia are said to derive benefit here, especially cases of acute spinal myelitis, which are quickened in their recovery by a judicious use of the baths. "After the termination of the acute stage," says Braun, "which is marked by fever and violent eccentric pains, paraplegia develops itself *without paralysis of the sphincters, and without anæsthesia*; and this is the point at which the antiphlogistic treatment hitherto indicated must give way to that of baths." In other words, the cases must be in a fair way to recover in order that the magical effect of Oeynhausen shall be produced. Having seen the baths of Oeynhausen, and having read what Braun, its chief apostle, has to say upon the subject, the Englishman will ask himself seriously whether it can be worth while to send patients from England to Oeynhausen.

The results obtained by sending scrofulous subjects to Margate and other bathing-places on the east coast are so splendid, often bordering on the miraculous, that we are not likely to grow dissatisfied with them, or to imagine that Oeynhausen can effect what Margate cannot. It must be better to bathe in the sea than in a room more or less filled with carbonic acid, and it must be that the carbonic acid escaping from the Oeynhausen water is inhaled by the bather. Skin-culture is certainly much better understood in England than in Germany, and when our Teutonic brethren have studied our habits a little more attentively, they will perhaps, learn that a rough towel is, as a skin-cultivator

much better than carbonic acid, and has the great advantage of producing no deleterious effect. Bathing quickens and stimulates nutrition, and it is essential that baths of all kinds should be taken in the purest air possible.

As regards the relief of paralytic troubles, I may remark that, "There is a tide in the affairs of paraplegia, which, taken at the flood, leads on to fortune." In cases of spinal hæmorrhage, and in cases of localised meningitis, especially if the subjects be young, there comes a time when, after a prolonged rest in bed, the pathologic conditions reach that minimum stage which we call a cure, and the spinal cord is ready to resume its functions and rouse from the dormant state engendered by the injury and the enforced rest. Then is the time to stimulate the skin (which in such cases always becomes dry and harsh), and there is nothing better than baths and friction. Such favourable results have been obtained in these cases by simple warm water and rough towels that it would be difficult to believe that Oeynhausen could accomplish more than can be attained by ordinary simple methods.

With regard to the effect of warm bathing and "skin culture" on gout and rheumatism there can be no doubt, but in connexion with this subject it may be well to recite a case which has come very closely under the writer's observation. A single lady, aged thirty-six, in the summer of 1876 was suffering from "gout." There was nodular enlargement of the finger-joints and of the toes, and some of the bigger joints were also affected. A similar condition existed to a marked extent in a maternal uncle and aunt. The patient was somewhat pale, and slightly inclined to be stout. Her habits were most abstemious, and at the time when she first came under observation she was very weak, and quite unable to walk except very slowly. In the summer of 1876 she was sent to Spa, where she took constant warm baths, and from there went to Homburg, where she continued her bathing. After some three weeks she was no better. The baths were given up, and it was resolved to try what life in the open air would accomplish, together with a daily perspiration induced by exercise. A start was made in the middle of August for the Black Forest and Switzerland. The patient rose at six, spent the whole day in the open air, carefully avoided all crowded rooms (such as the salons of hotels at night), took as much exercise as she could accomplish (which at first was very little), and went to bed at nine. The result was wonderful. At the end of three weeks she was able to walk from Airolo to Andermatt, over the St. Gothard, and returned to England in robust health. She continued well till the present summer, when the symptoms took a fresh start, and the fingers, toes, elbows, and ankles were attacked. The treatment so successful in 1876 was repeated, and a walking tour in North Germany was undertaken (not, be it observed, in a high mountain district, as was the case in 1876); and, notwithstanding the implication of one ankle, she was encouraged to use it as much as possible. The best results followed, and in a little time she had no difficulty in walking ten miles a day, sleeping well, eating well, and able thoroughly to enjoy existence.

Before giving credit to the effects of baths and mineral waters, one must be acquainted with the results obtainable by a natural and a simple mode of life. If patients would go to some healthy locality and make it a rule to spend at least fourteen or fifteen hours in the open air, to take all the exercise possible, and enjoy the daily luxury of a good vulgar "sweat," followed by a rapid sponging and a dry rub, avoid crowded rooms, eat simple food, and practise the rule of "early to bed and early to rise," I believe that a wearisome sojourn in some foreign Bethesda might often be avoided.

Obituary.

SURGEON-MAJOR BRYDEN,
BENGAL ARMY.

OUR columns last week announced the death of another distinguished member of the Indian Medical Service. Dr. James Lumsdaine Bryden died at Upper Norwood on the 18th ult. at the early age of forty-seven, leaving a widow and three young children to mourn his loss. Dr. Bryden was educated at the High School, Edinburgh, receiving his

medical education also in the university of that city, obtaining his M.D. degree in 1855. He entered the Bengal Medical Service in 1856, and served through the Indian Mutiny, being present at the siege of Delhi and relief of Lucknow—medal and two clasps. He was for four years civil surgeon of Buxar, and was then transferred to Calcutta for statistical duty, shortly afterwards being appointed "statistical officer to the Sanitary Commissioner with the Government of India," which office he held till compelled by failing health to leave India in August last. For more than ten years Dr. Bryden worked uninterruptedly at the important subject of the statistics of the European and native armies of India and of the gaol population; the voluminous and able Blue Books published by Government under his authority are too well known to require further reference in these columns. They are the result of unceasing labour and patient research on a subject hitherto entirely neglected. The time and thought bestowed on their compilation were immense, and proved even too much for a frame endowed by nature with robust strength and physique. Bryden broke down under the strain of incessant work, the value of which had been barely, if at all, recognised by the Government, whose faithful and able servant he was. He died in harness.

One who knew him well and intimately writes: "Sensitive, modest, and retiring, to a degree seldom met with but in men of the finest and most highly-strung moral fibre, Bryden's life was one long self-sacrificing consecration to duty. Had he been endowed with a larger share of noisy and obtrusive self-assertion his talents might have advanced him to a much more prominent position than that accorded to him by the Government of India under the long-sounding but subordinate title of 'Statistical Officer to the Sanitary Commissioner with the Government of India.'" There is only too much reason for the suspicion that the absence of appreciation of his long and valuable services on the part of the Government of India, or at least the delay in the expression of any such appreciation, until over and beyond the time at which such an acknowledgment would have been gratifying and inspiring to him, contributed to increase the mental depression which is such a frequent accompaniment of the insidious disease under which he laboured, for a longer period than he or his friends were aware of—viz., Bright's disease. With all Bryden's philosophic knowledge of the subjects which had become the study of his life, was added an intense power of concentration and that painstaking accuracy as to details which is such a frequent as to be an almost essential attribute of genius—this depth of insight and breadth of view concerning the vast problems involved in the consideration of the vital statistics of our Indian Empire, entitling him to rank among the most advanced of medical philosophers and thinkers,—was combined with a disposition so gentle, simple-minded, and childish, as to endear him to all who came under its winning influence. Within the sacred precincts and associations of the home circle his affectionate and loving nature exhibited its fullest development and enjoyed its most prized rewards. He was truly, and without exaggeration, one of those "pure in heart who shall see God," and although dead he still speaketh to all sincere workers by the example of his gentle and devoted life, for his works live after him.

He was interred at the Norwood Cemetery on November 22nd, being followed to his grave by his only son, a boy of eight years, a few relations, intimate friends and brother officers; among the latter were General Harrington, of the India Office, and Brigade Surgeon L. Kidd, of the Army Medical Department.

DR. WILLIAM LAUDER LINDSAY.

WE regret to record the death of this much-esteemed physician, which took place at 3, Hartington-gardens, Edinburgh, on the 24th ult., at the age of fifty. Wm. Lauder Lindsay, M.D., F.R.S.E., and F.L.S., was a talented and apt scholar at the Royal High School in 1845-6, where he carried off six medals and other honours. He was appointed medical officer to Murray's Royal Institution for the Insane at Perth in 1854, which appointment he held for a quarter of a century. He took his degree in medicine at the University of Edinburgh in 1852, when he distinguished himself as a student of no ordinary type, having obtained many honours. He was also a thesis medallist. Lindsay was a keen botanist,

having collected a valuable and rare herbarium, lichens having been his favourite study. Geological research was only second to that of botany. He held medals from Edinburgh University for botanical dissections, 1848 and 1849. Among the honours Dr. Lindsay obtained after his graduation, we may mention First Neill prize of the Royal Society, 1859; Gold Medal from the London International Exhibition of Fine Arts; Medal from New Zealand Exhibition, 1865, and Medal from the Royal Society for eminence in Natural History. His popular "Memoirs on the Spermatogones and Pycnides of Lichens" was his first published work in 1870, which was followed by "The Superannuation of Officers in British Hospitals" in 1875, and his last and best effort was published in 1879—namely, "Mind in the Lower Animals in Health and Disease" (2 vols., Kegan Paul and Co.). Lindsay's pen was seldom idle, as we find a long series of articles on "Cholera," "Glycerine," "Insanity," "Toxicology," "Therapeutics," and "Hygiene," published in the medical journals. He was ever fond of books; in fact, almost a bookworm, even spending his pocket-money when at the High School in purchasing standard works; he was especially fond of Scott and other celebrated authors. In consequence of enfeebled health he relinquished or resigned his duties at Perth in November, 1879. He suffered from severe dyspepsia, and could eat little food. Various remedies were tried, and several changes of climate were advised, but to no purpose. His health gradually declined during this year, and he died from absolute exhaustion of mind and body. In private Dr. Lindsay was most unobtrusive and retiring, and usually shunned the company even of his oldest friends. He shrank from ostentation, marked even in his death, having left orders that his body was either to be cremated or buried in a plain deal coffin. At all times unwilling to trouble any one, he was nevertheless deeply sensitive to the kindness of his medical brethren. Dr. Lindsay had been a widower for seventeen years, and has left one daughter. His only brother is Dr. Murray Lindsay, physician to the Derby County Asylum. We may only add that Dr. Lindsay was very reticent in regard to his religious views; he was a member of the Free Church of Scotland.

Medical News.

UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent M.D. Examination:—

Buchanan, Arthur, Guy's Hospital.
Cattle, Charles Henry, Leeds and University College.
Chapman, Paul Morgan, University College.
Colquhoun, Daniel, Charing-cross Hospital.
Dunbar, James John Macwhirter, St. George's Hospital.
Ferrier, John Christian, Guy's Hospital.
Gristock, William, Univ. College and Westminster Hospital.
Henderson, G. Courtenay (Gold Medal), University College.
Jones, Arthur Henry, Guy's Hospital.
Lubbock, Montagu, Guy's Hospital.
Mackern, George, Guy's Hospital.
Phillips, Sidney Philip, Univ. College and Middlesex Hospital.
Sainsbury, Harrington, University College.
Silcock, Arthur Quarry, B.S., University College.
White, William Hale, Guy's Hospital.
Wiglesworth, Jos., Liverpool Royal Infirmary and St. Thomas's Hospital.
Wilkinson, Arthur Thomas, B.A., B.Sc., Owens College.
Willcocks, Frederick, King's College.

LOGIC AND PSYCHOLOGY ONLY.

Bond, James William, B.S., University College.
Lendon, Alfred Austin, University College and Middlesex Hospital.
Plumbe, Samuel Thomson, St. Bartholomew's Hospital.
Prowse, Arthur Bancks, St. Mary's Hospital.
Ryley, James, University College.
Williams, Dawson, B.S., University College.

The following gentlemen have passed the Second M.B. Examination (Honours):—

MEDICINE.

FIRST CLASS.

Newsholme, Arthur (Scholarship and Gold Medal), St. Thomas's Hospital.
Money, Angel (Gold Medal), University College.
Saunders, Arthur Rich, University College.
Barnes, George Frederick, St. Bartholomew's Hospital.
Sellers, William, University of Edinburgh and London Hospital.
Meek, John William, Guy's Hospital.
Pollard, Bilton, University College.
Paddle, James Isaac, B.A., B.Sc., University College.
Suckling, Cornelius William, Queen's College, Birmingham.

SECOND CLASS.

{ Brooke, H. Ambrose Grundy, B.A., Owens Coll. and Guy's Hosp.
 { Harvey, Alfred, Queen's College, Birmingham.
 { Shaw, John, St. Thomas's Hospital.
 { Wainwright, Robert Spencer, Guy's Hospital.
 { Baddeley, Charles Edward, King's College.
 { Dalton, Norman, King's College.
 { Penny, Edward, Guy's Hospital.

THIRD CLASS.

{ Day, Donald Douglas, St. Bartholomew's Hospital.
 { Sayer, Mark Feetham, University College.
 { Notley, William John, B.A., University of Edinburgh.

OBSTETRIC MEDICINE.

FIRST CLASS.

Barnes, G. F. (Scholarship and Gold Medal), St. Bartholomew's Hospital.
 Paddle, James Isaac (Gold Medal), University College.
 Banks, William, University College.
 Saunders, Arthur Rich, University College.
 Newsholme, Arthur, St. Thomas's Hospital.

SECOND CLASS.

Pollard, Bilton, University College.
 Sayer, Mark Feetham, University College.
 Rich, Arthur Creswell, St. Thomas's Hospital.
 Permewan, Arthur Edward, University College.

THIRD CLASS.

Sellers, William, University of Edinburgh and London Hospital.
 Dalton, Norman, King's College.
 Harvey, Alfred, Queen's College, Birmingham.
 Meek, John William, Guy's Hospital.
 Day, Donald Douglas, St. Bartholomew's Hospital.

FORENSIC MEDICINE.

FIRST CLASS.

Meek, John Wm. (Scholarship and Gold Medal), Guy's Hospital.
 *Paddle, James Isaac (Gold Medal), University College.
 †Banks, William, University College.
 †Shaw, John, St. Thomas's Hospital.
 Rich, Arthur Creswell, St. Thomas's Hospital.
 Money, Angel, University College.
 Berry, Frederic Haycraft, Guy's Hospital.

SECOND CLASS.

Newsholme, Arthur, St. Thomas's Hospital.
 Penny, Edward, Guy's Hospital.
 Pollard, Bilton, University College.
 Wainwright, Robert Spencer, Guy's Hospital.
 Saunders, Arthur Rich, University College.

THIRD CLASS.

Faulkner, John Thomas, Owens College.

* Obtained number of marks qualifying for University Scholarship.

† Obtained number of marks qualifying for Gold Medal.

The following gentleman passed the M.S. Examination :—
 Symonds, Charters James, M.D., Guy's Hospital

The following gentlemen passed the B.S. Examination :—

FIRST DIVISION.

Claremont, Claude Clarke, University College.
 Gill, Richard, B.Sc., St. Bartholomew's Hospital.
 Neale, William Henry, University College.
 Pollard, Bilton, University College.
 Sheppard, Charles Edward, St. Thomas's Hospital.
 Smith, Robert Percy, St. Thomas's Hospital.

SECOND DIVISION.

Day, Donald Douglas, St. Bartholomew's Hospital.
 Money, Angel, University College.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on Nov. 18th :—

STEDMAN, A., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Eppingham District of the Dorking Union.

STEELE, W. C., L.R.C.P.Ed., M.R.C.S.E., has been appointed Assistant Medical Officer and Dispenser at the Infirmary, St. Saviour's, Southwark.

WAGSTAFF, E. H., M.R.C.S.E., has been appointed House-Surgeon to the Hull General Infirmary.

WATSON, Mr. J. M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

YOUNG, W., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

Births, Marriages, and Deaths.

BIRTHS.

BAIN.—On the 22nd ult., at Bournemouth, Hants, the wife of Benjamin Bain, L.R.C.P.Ed., L.R.C.S.Ed., of a son, who survived his birth two days.

PEACEY.—On the 20th ult., at Lewisham High-road, S.E., the wife of William Peacey, M.B., of a son.

SKERRITT.—On the 30th ult., at Thornton Villa, Richmond Hill, Clifton, the wife of E. Markham Skerritt, M.D., M.R.C.P., of a daughter.

SMITH.—On the 1st inst., at Christ's Hospital, London, the wife of Dr. Alder Smith, of a son.

WHITTINGTON-LOWE.—On the 29th ult., at Llanrhyth, Hove-drove, West Brighton, the wife of R. Whittington-Lowe, M.D., Staff-Surgeon (Army), of a son.

MARRIAGES.

PHILPOTS—SHARP.—On the 24th ult., at St. Bride's Church, by the Rev. J. Scott Ramsay, M.A. (cousin of the bride), Harris Philpots, M.D., of Tavistock, Devon, to Wilhelmina (Mina), eldest daughter of William Sharp, Banker, of 5, Huskisson-street, Liverpool, formerly of Stafford and Manchester.

SAUNDERS—SOLOMON.—On the 27th October, at Sea Point, Cape Town, Henry William Saunders, M.B.Lond., F.R.C.S.E., of Rondebosch, near Cape Town, second son of James T. Saunders, of Carvalla Lodge, Upper Tooting, to Jeannie, sixth daughter of Henry Solomon, of Sea Point.

TINKER—ISHERWOOD.—On the 18th ult., at St. Paul's Church, Southport, by the Rev. W. Millington, M.A., Frederick Howard Tinker, M.R.C.S.E., L.R.C.P., only son of the late Frederick Tinker, F.R.C.S., of Hyde, Cheshire, to Sarah Ann, youngest daughter of James Isherwood, Esq., of Southport.

WAKLEY—DOERING.—On the 2nd inst., at St. Martin's-in-the-Fields, by the Rev. W. G. Humphry, B.D., Vicar, James G. Wakley, M.D., youngest son of the late Thomas Wakley, M.P., to Clementina Agnes Doering, eldest daughter of the late Major Sutherland G. G. Orr, Madras Cavalry.

DEATHS.

CEELY.—On the 27th ult., at Aylesbury, Robert Ceely, F.R.C.S.E., aged 83. Friends will please accept this intimation.

FAUSSETT.—On the 29th ult., William Faussett, M.B., F.R.C.S.I.

GRANT.—On the 24th ult., at Cleator Moor, Cumberland Garden, Milne Grant, M.R.C.S.E., L.R.C.P.Ed., aged 33.

JACKSON.—On the 3rd ult., at Linden Villa, 68, Laurel Grove, Penge, Surrey, Harriet, widow of Mr. William Jackson, Medical Bookseller and Publisher (late of King-street, Borough, London), in her 87th year.

LINDSAY.—On the 24th ult., at 3, Hartington-gardens, Edinburgh, William Lauder Lindsay, M.D., F.R.S.E., F.L.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS ETC. RECEIVED.

ALLEN, W. H., & Co.
Report of the Proceedings of the International Congress on the Education of the Deaf, held at Milan. With an Appendix. pp. 159.

Medical Diary for the ensuing Week.

Monday, Dec. 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL. — Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL. — Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL. — Operations, 2 P.M.

ST. MARK'S HOSPITAL. — Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL INSTITUTION. — 5 P.M. General Monthly Meeting.

MEDICAL SOCIETY OF LONDON. — 8½ P.M. Dr. Dowse will exhibit a Patient suffering from Tabes Dorsalis, with anomalous Symptoms. — Dr. Broadbent, "On Pleuritic Effusion."

Tuesday, Dec. 7.

GUY'S HOSPITAL. — Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL. — Operations, 2 P.M.

WEST LONDON HOSPITAL. — Operations, 3 P.M.

PATHOLOGICAL SOCIETY OF LONDON. — 8½ P.M. Discussion on "Rickets," continued by Dr. Norman Moore, Mr. Warrington Howard, Dr. Dickinson, Mr. Parker, Dr. Longhurst, Dr. Baxter, and Mr. Lucas. — Dr. Barlow: Case of so-called "Fetal Rickets." — Mr. Shattock: Osseous Lesion in the Fœtus. — Dr. F. C. Turner: Anatomical and Microscopical Specimens of Ricketty Bones. — Dr. N. Moore: Cancer of Prostate (recent specimen). — The President: Card Specimens.

Wednesday, Dec. 8.

NATIONAL ORTHOPÆDIC HOSPITAL. — Operations, 10 A.M.

MIDDLESEX HOSPITAL. — Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL. — Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL. — Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL. — Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

HUNTERIAN SOCIETY. — 7½ P.M. Council Meeting. — 8 P.M. Dr. C. Turner, "On a Case of Intussusception." — Mr. Waren Tay, "On a Case of Colotomy performed six years ago for supposed Annular Stricture." — Mr. Gilbert: "Notes on Cases in General Practice."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM. — 8 P.M. Living Specimens. — 8½ P.M. Dr. Hughlings Jackson, "On the Eye Symptoms in Locomotor Ataxy." — Mr. Higgens, "On Hypocleral Cyclotomy." — Mr. Critchett, "On Peritomy in Partial Pannus." — Dr. A. D. Davidson, (1) "On Detachment of Retina after Albuminuric Retinitis"; (2) "On Congenital Absence of one Eyeball." — Mr. J. E. Adams: "Peculiar Opacities in Vitreous Humour following Injury." — Dr. S. Mackenzie, (1) "On a Case of Scurvy with Retinal Hæmorrhages"; (2) "On a Case of Idiopathic Anæmia with Retinal Hæmorrhages."

ROYAL MICROSCOPICAL SOCIETY. — 8 P.M. Dr. Hudson: "Floscularia trifolium" (new specimen). — Mr. C. Stewart: "Some Structural features of Echinometridæ." — Notes on the Movements of Diatoms, the Construction of Object-glasses, Swinging Substages, &c.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE. — 8 P.M. Dr. A. Carpenter, "On London Fogs."

Thursday, Dec. 9.

ST. GEORGE'S HOSPITAL. — Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — 1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL. — Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE. — Operations, 2 P.M.

Friday, Dec. 10.

ST. GEORGE'S HOSPITAL. — Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL. — Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M.

QUEKETT MICROSCOPICAL CLUB. — 8 P.M. Ordinary Meeting.

CLINICAL SOCIETY OF LONDON. — 8½ P.M. Mr. Tyson (Folkestone), "On a Case of Pneumonia, with Remarks on the Physical Signs of the Disease." — Dr. Habershon, "On a Case of Aphasia, with Hemiplegia on the Left Side; Tumour on Right Side of Brain at third Frontal Convolution." — Mr. Norton, "On an Operation for the Radical Cure of Web-fingers." — Mr. Davies-Colley, "On a Case of Villous Growth of the Bladder successfully removed by Perineal Section." — Mr. Croft will show a Case of Cured Hydronephrosis. — Mr. Tyson will show a Case of Cross-legged Progression.

Saturday, Dec. 11.

ROYAL FREE HOSPITAL. — Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Lectures, original articles, and reports should be written on one side only of the paper.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

"TEMPERAMENTS."

THERE has been a good deal of hair-splitting among medical writers on the subject of temperaments. It is not worth while to revive the controversy, or even to recapitulate the names of classes under which the several "temperaments," as they are called, have been grouped. The truth is that the term "temperament" has been employed to designate very different qualities of the physico-medical organism—namely, general type and constitution, and—somewhat too vaguely perhaps—the temperament or temper in its true sense. The popular significance of this word temper—as applied to steel, for instance—holds good, and is especially suggestive and accurate as employed to describe the habitual state of the animal organism. A sound temper or temperament is a well-balanced and regulated condition of mind and body, wherein a healthy degree of tension, as it were, is maintained by the just equipoise and counter-action of the inherent qualities of which the nature is composed. An irritable temper or excitable temperament is one which is too highly or unevenly strung, and will therefore jar on the smallest provocation. A sullen, stolid, or dull temper, merging into moroseness, indicates a condition in which the tension is low, and certain of the more selfish faculties are not duly equilibrated. Just as in the muscular apparatus, if opposing muscles are not of equal strength or duly energised, the limb will not be in a state to act either quickly or continuously in obedience to the will; so in a temperament exhibiting want of due correlation of the inner forces, the judgment has seldom the whip-hand of conduct, and the active life of relation is almost sure to be defective. Temperament has much to do with health preservation. The sound and good-tempered resist disease, and pass unscathed through many dangers, as the stiff craft bending steadily to the breeze, and well under the control of her helm, may thread a narrow passage among the rocks, or as the horse that bears equably on the rein grasped by a firm hand can be driven safely through a crowded thoroughfare. The variable, uncertain, irritable, and, above all, the sullen of temper, are a misery to themselves and those around them; the troubles of life fret their strength, and the perils that lurk in their path can seldom be certainly and pleasantly avoided. There is no better way to live healthily and happily than to cultivate a temperament wherein the most contradictory qualities and properties of the organism are perfectly counterbalanced and combined.

Mr. W. Davison.—The question is entirely legal; but on moral grounds our correspondent seems well entitled to a quarter's salary. A friendly settlement should be quite possible.

Dr. W. R. Smith, (Cheltenham.)—Yes.

W. R.—Marshall on the Enlisting and Discharging of Soldiers, last edition.

M.D.—The use of the handbill with the adoption of a system of advertising is a sad exhibition of the want of professional taste and spirit.

Scapula.—As early as possible.

Lupus had better apply to one of the pay hospitals.

SCHOOL-BOARD CERTIFICATES.

To the Editor of THE LANCET.

SIR,—I am glad to see in THE LANCET of Nov. 20th a letter from a provincial house-surgeon on the above subject. As one of four assistants in a large railway practice, I can say that we are continually pestered with parents asking for certificates to say their children are unable to attend school; and not content with that, when the children are convalescent (if they have been suffering from fever of any kind), they again come, requesting certificates to say they are now fit to attend school, and are free from infection!—thus entailing great additional labour and responsibility on us. Surely if the School Board require medical certificates they should pay for them.

Yours faithfully,

Wilts, Nov. 1880.

H. B. F.

MEDICAL SERVICES IN SPAIN.

DR. ALVARO MENDEZ, the editor of *El Siglo Médico*, of Madrid, Dr. C. Velasco, of Nice, and Dr. de Pietra Santa, of Paris, have entered a protest against the tendency to look upon Spain as the last of nations with respect to sanitary and medical progress. Dr. Velasco remarks that now more than sixty years have elapsed since the Duc de Sesto, then the alcalde corregidor of Madrid, created the *casas de socorro*, an institution which might be imitated with advantage by many nations to the north of the Pyrenees. In each quarter of Madrid there is by law established a house where four to six beds are always held in readiness to receive any persons suffering from accidents or sudden illness, and whom it would be difficult to transport either to the hospital or to their homes. At each of these depôts there are two or three doctors, according to the importance of the district, two nurses, a clerk, and two stretcher-bearers. Both day and night a medical man remains on duty at this post, and he has with him the necessary surgical instruments, bandages, medicaments, &c. This institution is in vogue in all the large towns of Spain. The medical attendants receive fair remuneration, and are appointed by public competition. These appointments supply practice to young doctors, and enable them to tide over the earlier and more difficult period of their careers. For a village of forty poor families and 130 cottages and houses, the local authorities pay the medical man a yearly salary of £23, and the well-to-do inhabitants contribute £77. This total of £100 a year for a country so poor as Spain compares favourably with the sum our rural authorities give to their medical officers of health. The regular functions performed by the "inspectors of salubrity" and the municipal veterinaries, the organisation of a general service for vaccination for the relief of the poor, and the sanitary supervision of ships, all show that Spain is not far behind the age. Indeed, it must be acknowledged that in one respect she is even ahead of her neighbours. The Spaniards have erected two Orders as special rewards for devotion to the cause of public health. The first is a medal or decoration given to doctors who have distinguished themselves during periods of epidemics, and the other is the Order of Benevolence, given as the reward of acts of civic heroism, abnegation, and charity.

Mr. T. Bell, (Uppingham.)—The paper is marked for insertion.

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—Dr. Granville's able paper in your journal of October 23rd has opened up a subject of vast importance to the scientific mind of the profession. His argument on "intention" is a grand one, and, as he says, is not even yet recognised, and suggests that the province must be thoroughly explored. Therefore I wish to ask how sex is determined in the case of hermaphrodites, and in those monstrosities where there is no sex at all? What frustrates intention here? Again, for six or seven generations in some families male children only appear; the same in others for girls. Are the "constituent elements" of the "nature" so powerful as to pass through so many generations, no matter how ardent the male or female may be? And where is the "mean" of the two sets of qualities of both parents? Does the "direct" inheritance annihilate the "mean" for so long a time? As Dr. Granville has gone so deeply into the subject, perhaps he can smooth the way for those who wish to follow him by offering some explanation on these curiosities of genesis.

I am, Sir, yours truly,

Linslade, Nov. 22nd, 1880.

WM. STORY.

To the Editor of THE LANCET.

SIR,—“A. G. P.’s” difficulty, as stated in your last impression, would seem to resolve itself into some confusion existing in his mind about mental and physical qualities and the connexion between them in an individual, or else his language fails to give both himself and others a full grasp of his real meaning. Thus observation leads us to the conclusion—

1. Quite as much as sexes differ, so do minds, even in the same family, and minds will copy any model set before them.

2. Physical qualities of one parent may descend to children, or the physical qualities may be a compound of both, or may be qualities quite distinct from those of either of the parents, but in the latter case there is always one very distinct peculiarity which indicates how the exception arises.

3. A governing principle being assumed in the mere animal act, it is clear that principle can never be less than duplicate, just as it is impossible to govern mind on one principle.

4. This principle being never less than duplicate in ordinary cases, it is equally clear that where twins are born of different sexes, but with unity of placenta, there must be in such cases at least a third principle involved, as has, in fact, been demonstrated over and over again by those who have satisfied themselves there is nothing more to discover in that direction beyond the fact that mental and physical qualities are quite distinct.

There is nothing, therefore, to answer in “A. G. P.’s” query as far as his meaning can be apprehended.

Yours &c.,

Baden-Baden, Nov. 1880.

M.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the 82 candidates at the pass examination for the diploma of Membership of the College on the 12th ult., when they were required to answer at least four (including one of the first two) out of the six questions:—

1. Give the relations of the right common iliac artery, and state by what arteries the collateral circulation is established after ligation of that vessel.
2. Enumerate the structures which must necessarily be divided in excision of the scapula.
3. To what visceral complications may severe burns of the skin give rise, and to what stage of the case are they most likely to appear?
4. What is spina bifida? Describe the anatomy of the deformity, and the means you would adopt for its relief.
5. Describe the symptoms of a foreign body impacted in the larynx, and state how you would relieve the patient.
6. Describe the formation and treatment of fistula in perineo.

The following were the questions on the Principles and Practice of Medicine submitted on the following day to those candidates who had not passed a recognised medical examination:—

1. Give the symptoms, course, complications, and treatment of acute rheumatism.
2. Describe the symptoms and course of tubercular meningitis. Note the distinctions which separate it from the diseases which clinically resemble it, and mention the appearances commonly met with after death from this cause.
3. State the effects, preparations, and doses of digitalis, elaterium, colchicum, acid tartrate of potash, and perchloride of mercury.

A POET'S LAMENT.

A WRITER of considerable merit, Xavier Aubryet, died in Paris on Monday, the 15th November, of locomotor ataxia. He had suffered for the last six years from the disease in its severest form. Some time back he published a book which was written towards the beginning of his illness, entitled “La Maladie à Paris,” and he had intended to publish a work written afterwards, and which he considered to be his *chef-d'œuvre*; but the progress of the disease had deprived the author of his sight, and none of his friends could decipher the handwriting. The *Figaro* in its obituary notice gives the following verses, which were written by Aubryet to describe his sufferings:—

LE VIOLON DE DIEU.

Quel Stradivarius pour la douleur physique
Que l'étrange instrument qu'on nomme corps humain !
C'est Dieu qui pour lui seul compose sa musique,
La main qui tient l'archet, c'est sa terrible main !

Quelles vibrations que nos cris de souffrance !
Quelles cordes d'un jeu tout-puissant que les nerfs !
Désespoir, pour trouver toute la résonnance,
Les bois les plus fameux valent moins que nos chairs !

Quelle gamme sans fin de la plainte uniforme !
Quel dessin de douleurs sur des thèmes mortels !
Comme ils vous envierient, les maîtres de la forme,
Pizzicati sanglants et points d'orgue cruels !

Elle a trois clefs aussi cette musique noire :
Dans le mal au début, la clef du purgatoire,
Quand il est sans espoir, c'est la clef des enfers,
La clef du Paradis quand la mort rompt ses fers !

XAVIER AUBRYET.

“THE CHLOROFORM DEATH-BILL FOR TWELVE MONTHS.”

To the Editor of THE LANCET.

SIR,—Under the above heading, in THE LANCET of the 6th instant, Dr. Jacob of Leeds reports twenty-five deaths from chloroform during the past year. He names the operation in twelve cases, and certainly there is reason for the remark that the operations were of the simplest kind. Anyone who has interested himself in the cases of death from chloroform, reported from time to time, must have been struck with the frequent occurrence of fatal results in what are usually called “simple operations.” As far as I have observed, the largest number of deaths have occurred during extraction of the toe-nail, extraction of teeth, and operations on the eye. Now, these are frequently, I may say almost invariably, performed while the patient is sitting upright, or, at all events, not in a recumbent position. This, I believe, more than any other cause will explain the many deaths during “simple operations.” In the twelve cases cited by Dr. Jacob, any of them, with the exception of excision of the breast, might have been, and probably were, performed whilst the patient was sitting upright.

There are very few operations, if any, which may not be performed while the patient is lying down, and it seems to me that an unnecessary risk is run when chloroform is administered in any other position. My personal experience in the administration of chloroform does not go beyond 2000 cases. I have never had an accident, and, for the last twenty years, have made it a rule never to administer it unless the patient be in the recumbent position. The only cases in which I have observed the anæsthetic produce anything like dangerous symptoms were in excision of the eyeball. I suppose that this fact has been observed by other surgeons.

I am, Sir, yours truly,

Florence, Nov. 13th, 1880.

G. DODS.

A CHANGE IN THE WIND.

THE Holborn guardians, according to the *Metropolitan*, have discovered that the patients in their infirmary sell the spirits served out to them as medicine. Commonly the complaint is that the poor too often turn what money they can get into drink; but in this case they turn drink into money. What they do with the latter may be a question of some interest. In other words, what for them has charms superior to those of drink?

Dr. G. Stanley Murray.—Our correspondent takes, it seems to us, a sensible view of the matter, and expresses it in terms so reasonable that we do not care to do more than assure him of our concurrence. Such qualities should be used in an unselfish way for the gratification of others, and, provided the use of them is not allowed to interfere too much with professional work and that scant leisure for study which keeps a man abreast of his art, it cannot be too highly commended. Some very distinguished members of our profession have so used "the gift that was in them."

Fairplay should address his complaint to those whom he holds to be responsible for the *lâche*.

G. should consult an analytical chemist.

Dr. Ridpath should write again. His former letter has probably miscarried.

TONGA.

To the Editor of THE LANCET.

SIR,—I have by the last mail received from Dr. Bancroft, of Brisbane, some information respecting "tonga," a medicine used for neuralgia, which I think will interest many of your readers.

"Mr. Christy having been making inquiries about the remedy for neuralgia called 'tonga,' obtained from Fiji, and by the kindness of his botanical friends has ascertained that a gentleman who lived on one of the Fijian Islands, away from all medical assistance, was for years a martyr to neuralgia, and unable to find any remedies to give him relief. In this hopeless condition he began to try the leaves, bark, fruit, and roots of every plant that grew wild on the island where he was living. He pounded the leaves &c., mixed them with water, used the preparation externally, and drank it as well. Any of these that gave him relief he placed on one side; still he kept on trying various plants. At last he had three or four remedies, each of which afforded him partial relief, and when the whole of these were mixed the effect was magical. He refused to give further information as to the plants, except that the 'tonga' is a combination of several, bark of one, leaves and roots of others. He wishes to make what profit he can by the sale of his remedies. He is a German, and unacquainted with botany. He and a friend who introduced the medicine in England are the only persons who know the composition of the tonga remedy."

I have omitted the names from the above letter, as one of the party is very ill, and the other is only the party who forwards the article. The question will naturally arise, How could any man unacquainted with the plants on a tropical island arrive at such a happy result as tonga appears to give? If it is correct, which has been surmised, that one of the parties married the daughter of a Chief, nothing would be more natural than that the medicine-men among the Indians should be instructed to search for certain drugs, known perhaps only to themselves, which gave relief, then by combining those which appear to answer best, the composition "tonga" may have been easily arrived at. This report bears out the opinion of some scientific men who examined for Messrs. Hanbury and Co. the composition of the small bags the tonga came over in. They have decided there are certainly more than one variety of plant, root, or stem in each bag.

Dr. Bancroft, who is known to have carefully studied the native drugs in Australia, sends me some other information respecting "Alstonia constricta," which he has used in the hospital for ten years. He says: "I make into tincture of alstonia two ounces of bark to twenty ounces of proof spirit; one or two drachms in half a pint of water gives a fluid scarcely to be distinguished from solution of quinine. I have also used it in my private practice for a similar period, and still use it. I have poured some tincture into a tumbler with water, and asked old experienced surgeons if they knew what it was. They invariably said 'quinine!' I am sure there is a large future for this valuable drug, the bark of which can be got at such a low price in this country, and I think it is a pity medical men do not use it more generally in England. I am glad to hear that in America the demand for the alstonia is daily increasing."

Dr. Bancroft has also sent by this mail some pounds of pituri leaves.

Nov. 27th, 1880. Yours truly,
THOS. CHRISTY, F.L.S.

T.—See the Home Hospital, Fitzroy-square, and visit the Parkes Museum of Hygiene, University College. In the first place, our correspondent will get all the knowledge he requires if the hospital he is interested in is within a sewered district; in the second place, he will probably learn all he needs if the hospital is situated outside a sewered district.

Mr. Gillespie.—Thanks.

THE following paragraph appeared in the *Daily Telegraph* of the 19th ult. Comment is superfluous:—

"MEDICAL.—Wanted, a Diploma (registerable).—Address, Mr. _____."

Mr. L. Newton.—Attendance is generally expected, and when, as usually happens, the magistrate is not a medical man, it seems expedient.

"WANTED, A DIAGNOSIS"; GIVEN, A SUGGESTION.

To the Editor of THE LANCET.

SIR,—Your correspondent, "L.R.C.P.," probably has to deal with a gouty kidney.

I will give an illustrative case. It is that of a distinguished and highly honoured member of our profession, who had practised most successfully for many years in one of our larger West Indian colonies, and who died recently in this country, after a well-earned retirement of about four years' duration. I had attended him along with other medical men for many years in the Greater Antilles. He was subject to most frightful attacks of inherited gout. During the attacks his urine was invariably non-albuminous. At all other times (for he regularly examined it himself) it was highly albuminous. Being a man of great power of will, and of indomitable courage and energy, he was intensely annoyed by the frequent interruptions caused to a large and lucrative practice by these attacks of gout, and at length resorted to "Leville's drops"—a mode of treatment much affected by the French residents of these regions. The effect of that "secret" medicine (said to contain veratria) was simply marvellous so far as concerned the usual gouty manifestations. These consisted of enormous swellings of the knees, ankles, &c., which would shift from the one side to the other of the body in the course of a few hours. He would be able under the influence of "Leville" to go on with his work, visiting from sixty to seventy patients a day, besides doing his consulting-room business. One result, however, was most distressing: Dr. — has often told me that he purchased the "repression" at a frightful expense mentally, and used to say that after taking his "Leville" he felt in danger of suicide (ordinarily an idea that, owing to his fixed religious and firm moral convictions, could never enter his vigorous mind) unless he "worked it off." At such times his urine would be more densely albuminous than ever; it would solidify in the tube. The patient went on in that kind of way for many years, taking his "Leville" after his retirement even occasionally, and having albuminous urine to the last, which happened at the age of sixty-six. He never had dropsy in any form, unless oedema of the lung, towards the end, could be so called.

I submit, Sir, that we have here a case which may help in the elucidation of "L.R.C.P.'s" doubts. If I be right, your correspondent may go straight through the Pharmacopœia, adding to the formidable array of drugs stated as already tried until he has tried them all; but he will not influence the albuminous condition of the urine unless a regular gouty attack should in some way or other be manifested or brought about. Again, the albuminuria having, it is stated, existed for so long a period as four years, without the occurrence of such symptoms as usually happen within that time, in Bright's disease, I think that actual nephritic change may be eliminated from the diagnosis. It is not improbable that the occurrence of the "fit" twelve years ago betokened the starting point of something, seeing that it occurred at an age when, in my experience, the gouty tendency sometimes shows itself somehow—in dyspepsia for example,—particularly if a predisposed person have not been careful in his mode of life; nor is it out of the bounds of probability either that the albuminuria may have existed unnoticed all these years. But we have no positive evidence either way as to this. Moreover, it seems to me that the eruption of acne and the "warm feeling across the lumbar region" show that a *materies morbi* of some kind has, and is, trying to eliminate itself.

There remains the question of syphilis, stated to have been contracted some years ago. In my experience, syphilitic albuminuria, so to call it, for I have often seen it, yields either to iodide of potassium or to mercury cautiously given, so that this, too, may perhaps be put aside.

It would be out of place here to offer any suggestions as to treatment, which indeed are not asked for; but if my hint should lead to anything, I shall be happy to write to "L.R.C.P." privately, through you, if he wishes.

Shaldon, Nov. 1880.

Yours truly,

M.D.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent in your issue of Nov. 20th, I look upon his patient's case as one of latent gout, and would consequently advise that he give him a little colchicum for a week or two, carefully watching its effects upon the system; and would suggest the following mixture:—Carbonate of ammonia, forty grains; bicarbonate of soda, one drachm and a half; tincture of colchicum seed, two drachms; syrup of oranges, four drachms; water to eight ounces: one-eighth part to be taken twice daily (at 11 A.M. and 4 or 5 P.M.) Let him abstain from alcohol for a fortnight, taking meat once a day and fish once a day, and I prognosticate that at the end of a fortnight his morbid sensations will vanish, as well as the albumen from the urine. A warm bath might aid in the cure.

Earl's-court-road, W., Nov. 23rd, 1880.

E. MAY, M.R.C.P.

To the Editor of THE LANCET.

SIR,—If "L.R.C.P." can refer to Niemeyer's Medicine, he will see at once that his case is one of chronic Bright's disease. The treatment recommended is: Give plenty of protein substances, as soft boiled eggs, strong meat broths, roast beef, &c., in as large a quantity as the patient can digest; a moderate quantity of beer or good wine; quinine and iron mixture. Sometimes an exclusive milk diet is successful. Hot baths and cream of tartar and Dover's powder are also often of use. Avoid squills, cubebs, copaiba, and other irritating diuretics, also ardent spirits.

Yours truly,

Hayward's Heath, Nov. 22nd, 1880.

A. H. NEWTN.

THE ANTIGUA WEEKLY REGISTER.

THE case seems to have been one of placenta prævia; but we cannot comment on it without more particulars than are contained in the newspaper report. It is to be greatly regretted that a medical man did not go to the assistance of the midwife.

Mr. William Bund.—Apply to one of the hospitals for the relief of nervous diseases.

Mr. Roger Williams.—The paper will appear in an early number.

FISH-EATING AND LEPROSY.

To the Editor of THE LANCET.

SIR,—In your issue of the 6th instant you publish a letter from Mr. Jonathan Hutchinson, in which he contests Mr. Startin's conclusion that, in the case of leprosy recorded by him in your number of the 30th ult., the disease could not in that case be considered due to a fish diet, and states "that I have not seen a single instance of leprosy in which the fish hypothesis was impossible; nor do I know of a single district where the facts, when sifted, are strongly opposed to it"; and he concludes by asking for particular information as to leprosy in certain districts of India.

I cannot give him the information as to those districts; but I can give some as to another district in India which bears upon the point under discussion, and appears to me strongly opposed to the "fish hypothesis." At Bangalore, the principal military and civil station in the Mysore territory, with a population of over 120,000, leprosy is by no means uncommon among all classes of the native population, inclusive of Brahmins, whose customs in that part of India as to diet are so exclusively vegetarian as to completely exclude the use of fish; eating it would involve pollution and expulsion from caste. Having held medical charge of the civil hospitals on the station for over ten years, I can say that I have seen there a good many Brahmins affected with leprosy.

I am, Sir, yours &c.,

J. KIRKPATRICK, M.D.,

Retired D.S.G., Madras Establishment.

Edinburgh, Nov. 11th, 1880.

APPLICATION OF CALOMEL DUST IN THE TREATMENT OF PTERYGIUM.

To the Editor of THE LANCET.

SIR,—The treatment of pterygium by calomel dust was frequently adopted by Mr. Henry Power at the Royal Westminster Ophthalmic Hospital as far back as 1870, during the tenure of my house-surgeony under that gentleman. The treatment appears to be new in Tokio, but it is not in London. Calomel and quinine dust used by Mr. Power proved to be exceedingly efficacious in some cases, especially in those of debility. Quinine, calomel, oxide of zinc, &c., are valuable in pterygium, corneal opacities, granular lids, and all such pathological states.

I am, Sir, yours obediently,

Staines, Nov. 22nd, 1880.

Clinical Lectures

ON

DISEASES OF WOMEN,

AS LINKED WITH GENERAL PATHOLOGY.

By ROBERT BARNES, M.D.,

OBSTETRIC PHYSICIAN TO ST. GEORGE'S HOSPITAL.

LECTURE IV.

ON THE GENITAL MUCOUS TRACT—(Continued).

Dysmenorrhœa by retention; menopause; association of stenosis of os externum uteri with dysmenorrhœa and sterility; treatment—dilatation, bougies, leeches, incisions of the os externum, advantage of.

GENTLEMEN,—In the preceding lecture we referred to the pathological consequences of stenosis or closure of mucous canals, discussing particularly the consequences of closure of the genital mucous canal. Glancing at other properties of mucous canals, we dwelt upon the great fact that all mucous membranes secrete, that their secretions must have an outward vent, and that to obstruct this vent is to expose the patient to serious disease or danger. This law applies not alone to the openings of the great mucous canals of the respiratory, alimentary, and urinary organs, to close which is death, but in minor degrees to obstruction of the subsidiary divisions of these great tracts, and even to the glands and glandules which open on their free surfaces. And there are degrees of obstruction from total closure to stricture or narrowing, involving minor but yet not inconceivable evils.

Another general physiological remark. As elsewhere, the utero-vaginal mucous membrane and its glands are under the influence of the nervous centres. Emotion, we know, causes diarrhœa, salivation. It seems that the nervous centres in their normal static condition exert a regulating and inhibitory control over the glandular system, through the vascular system. When this static balance is lost or overturned, the glands pour forth their secretions with astonishing profusion. This sudden secretion is in marked relation to the dominant play of the emotional and reflex actions. Examples readily occur. I will only stop now to remind you that the influence of emotion and reflex action is not limited to mucous secretions, but that in the case of the uterus it may extend to the rapid outpouring of blood, even in dangerous volume. In this connexion you will not fail to remember that blood finds a normal exodus by the uterine mucous membrane. Let me recapitulate some of the consequences of obstruction to the ready escape of fluids, mucus, or blood, which may thus sometimes slowly, but not seldom rapidly, even suddenly, be poured into the cavity of the uterus. First, there is mechanical distension, exciting colic or spasmodic contraction; secondly, the probability of some of the compressed fluid being driven into the peritoneal cavity through the Fallopian tubes; thirdly, the retained fluids undergo changes by decomposition; fourthly, the thinner parts of the retained fluids, easily charged with septic matter, may be absorbed and carried into the circulation. This last event is seen in a striking manner in cases of concealed or "occult menstruation," with complete occlusion of the vagina, as where the hymen is imperforate; but it may be observed in more or less marked degree in most cases of dysmenorrhœa by retention. This is in accordance with a general pathological law. We have a familiar example in retention of urine from stricture or other cause. There is absorption of urine, causing urinæmia. We might not inaptly fix the fact in the mind by calling absorption of menstrual fluid from the uterus—"menopause." Evidence of this absorption may be found in the turbid complexion, in the peculiar fetid odour exhaled by the skin and lungs. Fifthly, the glands of the mucous membrane become irritated, inflamed, sometimes obstructed, hypertrophied. Consequently the mucous membrane itself is affected; its regular development into decidua, and its shedding are deranged, leading at times to the formation and throwing off of membrane in shreds or entire casts of the uterine cavity. Sixthly,

No. 2989.

the uterus itself is enlarged by hyperplasia, and in danger of passing into fibrous change. Seventhly, increased bulk and weight, and the reflex pains excited, promote prolapsus and retroversion. Upon these local conditions arise various constitutional disorders—hæmic, nutritive, nervous.

It is not difficult to trace this sequence of ills in many cases starting from stenosis of the os externum uteri. But you must be careful at the onset to avoid the conclusion that they are always and necessarily associated in this and in no other order. Dysmenorrhœa membranacea, other diseases of the mucous membrane, hypertrophy of the uterus, displacement, constitutional disorders, may arise in very different ways and from various causes. We are dealing at present simply with obstruction and its results.

There is another condition frequently associated with obstructive dysmenorrhœa—that is, sterility. So frequent, indeed, is this association, that when a woman has been married some years without having borne children, and has long suffered from dysmenorrhœa, we may predicate with tolerable certainty that there is stenosis or flexion of the uterus. And we may go further, we may assume that the dysmenorrhœa and sterility are both consequences of the mechanical obstruction, and acting upon this conclusion we may hold out a reasonable hope that by removing the obstruction we shall remove the attendant evils.

It must not, however, be hastily concluded that constriction even to a marked degree is infallibly attended by distress so great as to give rise to complaint on the part of the subject, or to lead to any obvious inroad upon her health. But I confidently affirm as the outcome of daily observation that in a very large proportion of cases of dysmenorrhœa, with sterility, there is the association with a narrow os externum uteri, narrowed to the extent that it barely admits the uterine sound.

I will make a further concession. It is not desirable in every case at once to resort to the *ultima ratio* of enlarging the os externum by incision. In very young, and single women especially, it is only proper to exhaust what are called "the usual remedies," although I must warn you that they usually fail. You take a careful survey of the system, interrogating all the functions, and do your best to correct whatever you find to be out of order. Thus having removed as well as you can all complications, you apply particular remedies to the relief of the distressed uterus. The complications, as constipation, dyspepsia, anæmia, are best dealt with in the intermenstrual periods. Then, when the period comes, you meet the difficulty in its simplest form. Pain, pelvic at first, frequently especially intense in the left iliac region—and therefore often supposed to signify ovaritis—then radiating to the hips, lumbo-sacral region, and thighs, commonly begins some days before the appearance of the flow. Generally the pain is at its acme on the first day of the flow, but often it goes on for two or three days, and throughout the flow. The pain that attends the flow is different in character from that which precedes. It is spasmodic, like colic, forcing, capulsive, resembling the pangs of labour, and the conditions are very analogous. The uterus is labouring to expel its contents, struggling to overcome a mechanical resistance. As commonly happens when the uterine fibre is put upon the stretch, especially in the cervical region, vomiting may occur. The whole nervous system is disordered. Partly under emotional influence, partly from disturbance of that regulating power which controls and guides in harmonious relation the several functions, diarrhœa may set in. Various other nervous symptoms break out. Hysteria, convulsions even, epileptic or epileptoid, neuralgia are manifest in severe cases and in impressionable subjects. The pain is often described as agony. The subject writhes upon the bed or floor. The mind, in spite of resolute will, loses its balance, and it gives way to delirium. By and by, the menstrual difficulty being overcome, things gradually resume their accustomed order, and the patient may for two or three weeks manifest perfect health. But these monthly blows struck at the nervous centres, these ever-gathering storms, cannot be encountered without leaving traces of damage. It can hardly be expected that the uterus itself, the centre of trouble, should escape unhurt. The seat of repeated and prolonged congestions, far surpassing the ordinary physiological hyperæmia, the mucous membrane of the cervix undergoes chronic thickening, its glands become hypertrophied, secrete in excess, and the secretion, from glairy, bland, and clear, becomes muco-purulent and irritating. This, like the menstrual

blood, is liable to retention; at least, it finds imperfect issue through the narrow os with difficulty and pain.

Now comes the crucial test of treatment—"Curatio ostendit morbum." The old saw never had a more satisfactory application.

Now, having fairly exhausted "the usual means," satisfied that they have failed, we arrive at the conclusion that it is best to remove the mechanical obstruction. How shall we remove the obstruction? By dilating the narrow os externum uteri, and by remedying flexion. If there is flexion only the treatment will, in the first place, be simply limited to restoring the uterus to its proper form and position. The modes of doing this we shall discuss hereafter. We will now consider how to deal with stenosis, and we have first to determine the exact seat of the stenosis. This, I believe, to be almost always at the os uteri externum. You see—every week we see examples amongst the out-patients—a minute round aperture that barely admits the sound, instead of the normal fissure, the classical os tince, which opens freely into the cervical cavity. When you pass the sound in such a case, two things are generally observed; first, the partial momentary dilatation of the sound allows the escape of a mucus, sometimes like molten glass, clear, viscid, sometimes viscid and turbid from admixture with pus-globules. This is the secretion from the irritated inflamed glands of the cervical canal. It cannot escape freely through the narrow os, more or less of it is long pent up, and becomes a source of irritation, often of pain, felt in the intermenstrual period. Commonly you also see the vaginal portion red, congested, and the minute os looks deeper red, angry, its epithelium partly or wholly shed, so that the slightest touch with the sound causes a little bleeding. And now, if you pass the sound gently to the isthmus or os internum, you may find an arrest at this point, but keeping well in mind the axis of the uterus, guiding the point of the sound by a finger upon the cervix you will rarely fail to pass through the os internum. This is proof that the seat of obstruction is not here; for the natural bore or calibre of the os internum, as you may see by these sections of the uterus, is just large enough to admit the sound. Why should we make it larger? I know of no valid reason. Anatomy and clinical experience alike protest. It is not only superfluous; it may be dangerous. The danger is especially great if dilatation be effected by cutting. If you look at these sections of the uterus and drawings again you will see that bloodvessels, in profusion and of considerable size, penetrate the substance of the uterus at this level. Large veins without valves and small arteries gape, and when divided are apt to bleed profusely, and present a ready entrance for septic matter. Nor can we be secure against dividing them. The incision must be made by a knife cutting out of sight; it must be difficult to regulate to a nicety the depth of the incision, the more so if you use one of those ingenious two-bladed machines, more or less automatic, and in so far out of the control of the operator. The only kind of assent I could give to the incision at the os internum would be to make a very slight nick, so as to divide the mucous membrane and some of the superficial circular fibres of the muscular coat. This may allay spasmodic sphincteric action. But I give even this qualified assent with considerable reserve, believing that the cases where it might be useful are rare. Of course, I am now speaking only of cases of dysmenorrhœa from stenosis. Freer incisions are sometimes eminently useful in severe metrorrhagia with fibrous growths.

Almost then excluding incisions of the os internum, we may turn back to the modes of dealing with the os externum. And we may first dispose of the alternative method of dilating by bougies, laminaria tents, and various expanding instruments. This proceeding is free from the risk of bleeding. If cautiously pursued there is not much danger of any kind. But if often repeated it becomes exceedingly harassing to the patient; the action of the laminaria tent is commonly very painful, vomiting often attends the expansion. After a time, usually very short, the canal will have returned to its pristine narrowing, and the proceeding has to be repeated again and again. To a certain extent the same objections apply to dilatation by graduated bougies, and other dilators. The pain is less, the regulation is more delicate, but the gain is not more enduring. Thus I have known not a few cases in which this kind of dilatation had been practised, at short intervals, over periods of twelve months or more, without any compensating gain. Then there is the method of rapid dilatation. This is effected

by instruments made with expanding or diverging blades on the principle of similar instruments devised for the urethra. This method is occasionally useful. The objections are that it hardly applies to the cases under discussion; that it is very painful unless anaesthesia be induced; that the gain is transitory; and that it entails no slight risk of metritis. Indeed, no mode of bloodless dilatation is free from this last danger. Instrumental dilatation, whether gradual or rapid, involves some degree of violence, and the penalty may be inflammation—that is, metritis, pelvic cellulitis or peritonitis.

Not rejecting these methods of dilatation, least of all that by bougies, I can only accord them a secondary place. The strictly limited incision of the os externum as I practise it, very nearly resembling the "discission" of the late Dr. Peaslee of New York, is at once less painful, more rapid, more certain, and more safe.

I need not dwell long upon the operation. You have so many opportunities of seeing it done that description is unnecessary. It consists simply in enlarging to a very moderate extent the os externum by help of a pair of scissors constructed *ad hoc*, one blade terminated by a probe-end, which enters the os, the other blade, terminated by a hook, which seizes and fixes the vaginal portion at the point desired. One stroke of the scissors divides the intervening tissue in a straight line. The proceeding is then repeated on the other side of the os, and the operation is completed. Two useful objects are at once achieved—first, the gorged vessels are relieved; you have gone far to cure the congestion and to relieve the chronic endometritis which so commonly attend this stenosis. This incision you have seen is equivalent to scarification, often a most effective remedy in congestion from other conditions. It is infinitely better than leeching, which I have long discarded for several reasons other than its inferiority to scarification—firstly, a leech is not an intelligent animal; it will not always bite exactly where you wish; sometimes it is obstinate, and will not bite at all; and it is not always a clean animal. It is more than suspected that its bite may, under certain circumstances, either inherent in the animal or in the patient, cause unhealthy inflammation. From this danger scarification is wholly free; it is, besides, more expeditious and more accurate. I may here mention that one of the conditions often met with in chronic congestions and inflammations of the vaginal portion is obstructed glands—the so-called ovula Nabothi. These form the foci of little inflamed areas. The cure for this condition is to prick or divide them with the scarifier; and it is remarkable how prompt and efficacious this treatment often is. It is true that these ovula Nabothi are not common in the nulliparous uterus. They most frequently occur in multipare, as a consequence of chronic inflammation—hypertrophy—of the cervix. In cases where the division of the os externum is called for, this scarification, or opening of ovula Nabothi, is, however, sometimes useful. It may be done at the same sitting. Now, these things, both essential to cure—the topical bleeding and the cure of obstructed glands—cannot be effected by bougies or other modes of dilating. The other immediate effect of division of the os externum is the letting out of imprisoned irritating mucus.

Now you have a patulous os externum, which means that you have secured free exit for uterine discharges, and free access to the interior of the cervical and uterine cavities for topical treatment. But, in truth, the chronic catarrhal state of the mucous tract is frequently soon relieved by the liberation of the os externum. There is a tendency to contract again after the operation. To meet this a variety of intra-uterine pessaries or stems have been devised. A modification of the late Dr. Wright's is the best. The principle of this lies in the divergence of the two halves of the intra-uterine portion by elasticity so as to maintain itself *in situ*. It is made of one piece of vulcanite. The next I should prefer is Meadows' glass stem. Both these are perfectly clean, and little apt to cause foul discharge. The elastic gum pessary is not free from this objection. The use of it entails some risk of causing septicæmia, local or general. But as a matter of experience, I do not find it necessary to use any contrivance of the kind. The simple operation is less painful, and not less satisfactory.

Next, menstruation is precipitated—that is, it sets in before it is due. Sometimes great relief is felt, but perhaps oftener two or more periods are passed without very sensible benefit. But it is in my experience quite exceptional for the operation to fail. It is hardly severe enough to call for

anæsthesia; but as the surgeon cannot always gauge accurately the sensitiveness, mental and physical, of the patient, it is desirable, whenever this sensitiveness is acute, to call in the beneficent ally that for the occasion blots it out.

This operation may be usefully modified in cases of marked curvature forwards of the cervix uteri. Instead of dividing the os externum bilaterally or transversely, Dr. Marion Sims splits the posterior lip—or what should be the posterior lip—in the median line. The effect of this is, in many cases, to make a more direct passage from the new os externum to the os internum, and thus to secure a readier evacuation of the uterine cavities.

We will talk of menorrhagia more particularly another time. This symptom is associated with various conditions. But it is in place here to call to mind that menorrhagia not infrequently accompanies the form of obstructive dysmenorrhœa we have now been discussing. The intense congestion induced by the difficulty of excretion, and the consequent turgidity of the mucous membrane, lead to hæmorrhages which exceed the physiological intention. Thus a pathological drain is set up, which, whilst it lasts, aggravates the other evils of the stenosis. This evil also is commonly relieved by the operation, or by topical medication to the interior of the uterus, which the operation enables us to carry out.

In some instances, however, the menorrhagia resists treatment for months. When once a woman has become the subject of recurrent hæmorrhages she begets a habit of making blood rapidly; the vascular system is periodically subjected to high tension; then comes the provocation of ovulation, which determines pent-up blood seeking a vent to the uterus, the natural safety-valve, whence it escapes in immoderate proportion.

To control this recurrent menorrhagia something more than topical treatment is called for. The vascular system, its central organ especially, has probably undergone some physical changes; certainly it has grown more irritable, it acts under exaggerated tension. Here, then, we find our indications; we have to moderate the blood-making process by careful diet, by exercise, by avoiding stimulants, especially malt liquors; to counteract the overfilling of the vascular system by careful promotion of due activity in all the excretory organs—lungs, skin, intestines, liver, kidneys; more particularly at the time of the flow to steady the heart's action by digitalis and salines, sometimes aiding this indication by the use of styptics or astringents, as ergot, hamamelis, gallic acid, sulphuric acid, turpentine, and other remedies of this order. But I must warn you that these too frequently fail unless their use is directed by a clear understanding of the time, sequence, and other conditions in their relation to the physiological and pathological principles which govern uterine hæmorrhages.

There is yet another feature we must not forget before closing this subject. After a time, if the stenosis is not removed, menorrhagia may give way to defective menstruation, even to amenorrhœa. The interference with the function gradually induces such changes in nutrition or such perversions of the circulation that the uterus no longer responds to the ovarian excitation. Sometimes relief is found in vicarious menstruation—menoxenia. In short, the obstruction is pretty sure, sooner or later, to bring disordered function here as elsewhere in the economy. To express by a generic term the disorders or perversions of menstruation we may conveniently use the word "paramenia," introduced by William Farr.

HOSPITAL AMUSEMENTS.—About 150 selected patients, the officials, a few families, the nursing "sisters" and the gentlemen attending the Medical School were recently invited to an afternoon performance in the Netley Recreation Room, when the Reverend Mr. Bateman, Lieutenant Condon, R.M.L.I., Surgeons Cottell, Polden, and Twiss delighted the audience with attractive songs, both grave and gay, for instance, "Cleansing Fires," "The Midshipmite," "The Trooper," and "Hearts of Oak." Clever reciters and amusing Ethiopian Minstrels belonging to the Army Hospital Corps also did their best to enliven the invalids. The manager (Dr. Hogg) announced that Surgeon-Major Boileau was preparing the next concert, and that every effort would be made to carry on a series, if people in the neighbourhood would only co-operate in volunteering to assist.

Clinical Lecture

ON

CASES OF ACUTE ATROPHIC PARALYSIS IN INFANTS AND ADULTS

(ACUTE ANTERIOR POLIO-MYELITIS).

Delivered at the National Hospital for the Paralysed and Epileptic, on Dec. 2nd, 1880,

By THOMAS BUZZARD, M.D., F.R.C.P.

LECTURE I.

GENTLEMEN,—Within a comparatively recent period the disease of which I shall show you some examples was called "infantile paralysis," or "essential paralysis of children," from its being thought to be peculiar to early life. It is now known to occur not at all unfrequently in adults; as Duchenne (to whom we owe an admirable description of the disease in children) was one of the first to point out. It is a form of "systematic" myelitis, to use a convenient term, suggested by Vulpian and adopted by Charcot, for lesions which are circumscribed within certain well-defined limits, without involving neighbouring parts. In this case the lesion is concentrated (to a great extent) in the anterior horns of grey matter of the spinal cord. Hence the term acute anterior polio-myelitis (*πολιός*, grey; *μυελός*, marrow; *itis*), has become applied to the disease, whether occurring in infants or adults. (To illustrate this subject reference was made to an excellent classification of different forms of systematic myelitis from Dr. Grasset's "*Maladies du Système Nerveux*," and also to a diagram from Dr. Charcot's lectures, showing the position of the various strands of fibres in the transverse section of the cord, copies of which hung in the hall.)

As it occurs in infancy (and it is peculiarly apt to attack children under two years of age) the essence of the disease is this, that after a varying amount of febrile movement, one or more or all of the limbs are observed to be paralysed. The muscles of the trunk also are sometimes involved, and very exceptionally some of those supplied by the medulla oblongata. There may have been convulsion, coma, some transient loss of cutaneous sensibility, and a temporary trouble with the bladder or rectum, but to a great extent (though not exclusively) the brunt of the disease falls suddenly, or at least very rapidly, upon the motor power of a limb or limbs. After the first day or so any change which takes place in the power of movement is a change for the better. The limbs do not become more paralysed. On the contrary, after a few weeks, or sometimes days, there is a gradual clearing off of the difficulty as regards some of the limbs, one or more perhaps remaining unimproved. There is a remarkable feature in this form of paralysis. Many of the muscles paralysed lose their faradaic excitability entirely within a week, and rapidly waste. But although they fail to respond to the strongest induced currents they react to slow interruptions of the constant current (reaction of degeneration). The nerves to the muscles, on the other hand, lose their excitability to both forms of electrical excitation. Some, again, of the muscles whose faradaic excitability has been lowered, but not lost, are not long in regaining the power of contraction to voluntary impulses. (Duchenne felt able, from his experience, to say that any muscles retaining some amount of faradaic excitability after the eighth day would recover.) The muscles paralysed are flaccid. This constitutes what is called the first period. The second begins a few weeks, or may be delayed for several months, after the attack. It is called the period of regression, for in it there is a gradual return of power in more or less of the muscles, and their excitability to faradism again appears. The amount of recovery differs extraordinarily in cases, so that it is impossible to say more than this that when several limbs are attacked at first it is much more common than not for some of them to recover, but rare for all to do so. In the sequel of the disease atrophic changes are marked

in the muscles, which may be so wasted as to leave the limb in a skeleton-like state, or fatty substitution may mask the real loss of muscular substance, and give a false air of plumpness to the limb. The development of the osseous system is more or less arrested, so that a bone may, in course of years, be some inches shorter, and considerably thinner than its fellow. There is diminution in the calibre of bloodvessels leading to comparative coldness and blueness of the limb, which also often shows unusual liability to chilblains. And most important of all, perhaps, the tonicity of such muscles as remain sound or comparatively little injured, causing them gradually to overpower those whose function is destroyed, gives rise to deformities which often tend to persist and increase in spite of all efforts to reduce them. Here are some examples of the disease at present under my care in the hospital.

CASE 1.—Ernest R—, aged four years, five months ago had a febrile attack lasting a few days, on recovery from which it was observed that he could do nothing with his *right leg*. The other limbs do not seem to have been affected. He has improved, so that he can stand and walk, although imperfectly, the limb being chiefly moved by the iliaco-psoas muscle, the knee-joint lax, very slight power of extending or flexing the leg, and none of extending or flexing the foot. This limb is smaller than the left, and Dr. Beevor, our resident medical officer, tells me the wasting chiefly concerns the quadriceps extensor, anterior tibial group, and peroneus longus, and also to a certain extent the calf muscles. So that the muscles most affected do not lie in the district of one nerve, and, on the other hand, all the muscles in the district of one nerve are not equally affected. The patellar tendon-reflex is absent, as you see, on the right side; present on the left. There is no loss of cutaneous sensibility. The muscles of the right limb when last examined did not react to faradism, but contracted to slow interruptions of a constant current from ten cells of a Stöhrer's battery.

CASE 2.—Daisy H—, aged one year and a half, fourteen months ago had a febrile illness which lasted about ten days, in the course of which there were convulsions, squinting, and loss of consciousness for three days. It was not till the end of this attack that the *right arm* was observed to be powerless. It remains imperfectly paralysed, the deltoid and biceps being especially wasted. She can move her fingers and hand, but cannot flex the elbow-joint, although she can extend it. The muscles of the arm show no response to faradism. They react to the interrupted constant current.

In such a case as this, having regard to the head symptoms, it may easily be suggested that we have to do with a cerebral hemiplegia. Now, when I tap the tendon of the supinator longus of the left side just above the wrist, there is a contraction of the muscle, and the forearm is suddenly, and, as you see, very perceptibly flexed. (The supinator longus, notwithstanding its name, is a flexor of the forearm, as Duchenne has shown.) On the right side, however, no such result occurs. This absence of tendon-reflex has the same significance as that which we saw just now in the case of the boy's leg. It means that there is a break in the nervous arc which connects the tendon with the muscle through the grey matter of the cord. The wasting of the muscles, their loss of faradaic excitability, the complete preservation of cutaneous sensibility, show that this break is on the motor side of the arc, and must be, therefore, having regard to other circumstances, either in the large ganglion-cells of the anterior horn, or the anterior roots of nerve. Now, if this were a case of cerebral hemiplegia, the tendon-reflex, if it were modified at all, would be exaggerated. It would not be lost, nor, again, would the muscles have lost their faradaic excitability. Cerebral hemiplegia may be confidently excluded. The fact that the deltoid (which with the biceps is the most affected muscle) is supplied by the circumflex nerve, and that the triceps (one of the least affected) is supplied by the musculo-spiral which comes from the same cord of the brachial plexus as the circumflex, shows, as also does the absence of cutaneous anaesthesia, that we have not to do with lesion of a nerve or of a plexus. We are driven further back, and seek the lesion, by exclusion, in the anterior horn.

CASE 3.—Arthur P—, aged four, nearly three years ago was observed to have entirely lost power (in one day) in the *left arm and leg*. No other symptoms were observed. He rather rapidly improved, and was in a few months as much recovered as you see him now. There really seems little or nothing wrong with his arm. The left lower extremity, however, is smaller than the right (the left thigh measuring an inch and a quarter less than the right), and he walks a

little lame with it. It is interesting to find that the patellar tendon-reflex is quite absent in this limb, little as it appears to be affected. And when we come to seek an explanation we find that faradaic excitability in the vastus internus muscle is distinctly although not greatly reduced.

CASE 4 (late in the hospital).—Ernest T—, aged fourteen years, had all four extremities and many muscles of his trunk paralysed about thirteen years ago. His limbs are short and small; patellar tendon-reflex absent on both sides. Feeble grasp with either hand; elbow-joints can be flexed and the left arm can be raised to level of shoulder-joint, the right cannot. In the upper limbs all the muscles react to faradaic currents in the following order of excitability: The forearms best, the arms next, the deltoids and pectorals least well. In the lower extremities no muscles (except those of the calves) react to faradism. In the right thigh there is still a slight reaction to the slow interruption of a constant current from forty cells. In the back the serrati magni and the mass of the erector spinae react to very strong induced currents.

In the next lecture I hope to show some examples of the disease in adults, and to demonstrate the changes in the electrical reaction.

NATURE'S PLAN IN THE DETERMINATION OF THE SEXES AND THE HEREDITARY TRANSMISSION OF PHYSICAL AND MENTAL QUALITIES, AND THE ACQUISITION OF NEW ONES.

By CHARLES ROBERTS, F.R.C.S., &c.,
LATE ASSISTANT-SURGEON, VICTORIA HOSPITAL FOR CHILDREN.

In a note "On Intention in the Determination of Sex," &c., published in THE LANCET for Oct. 23rd, Dr. Mortimer Granville asserts that "sex is determined by the relative ardency of the parents. A preponderance of impulse on the part of the male produces female offspring, while excess on the part of the female parent produces male progeny." Dr. Granville gives no statistical data in proof of his theory, but endeavours to support it by some confident statements as to the result of marriages contracted under conditions which would seem to indicate the relative affection of the two parents. I think it would be exceedingly difficult to obtain direct data in support of this hypothesis even by observing the lower animals, and such indirect data as we possess bearing on the subject in its relation to the human species is adverse to it. All physiologists and naturalists agree in asserting that the sexual instinct is stronger on the whole in the male than in the female; and whether we accept Darwin's or Wallace's theories of sexual selection, this fact must be accepted as the groundwork. Now, we find that in the human species the number of male births exceeds the number of female births in the following proportions: Great Britain 105.0, France 105.1, Austria 106.3, Italy 106.4, and Spain 106.5 males to 100 females. But these figures only represent the children born alive. If we take the still-births the proportion is much higher. In France 144, in Italy 140, Belgium 135, Sweden 133, and in Prussia 129 males to 100 females are stillborn; and if we combine the living and the stillborn, say in France, we have the proportion of 149.1 males to 100 females—a proportion which would, according to Dr. Granville's theory, imply a great excess of the sexual instinct in females; which is quite contrary to the opinion of those who have paid most attention to the subject.

But my object is not to endeavour to confute Dr. Granville's hypothesis, but to advance one of my own, based on such data and information as I have been able to collect while investigating the influences bearing on the physical development of the human species. It is exceedingly difficult to trace to its origin the purpose which Nature has had in view in differentiating the sexes.¹ It would seem that her plan has been to carry on the organism through the germ cell steadily and persistently in one direction, the germ dividing again and again, and reproducing itself with as little modification as possible, and with the least

¹ "I have often personified the word Nature, for I have found it difficult to avoid this ambiguity; but I mean by nature only the aggregate action and product of many natural laws, and by laws only the ascertained sequence of events."—DARWIN.

possible expenditure of vital force. Thus, females would produce females like themselves *ad infinitum*, if we imagine them, for the purpose of my hypothesis, capable of continuing the species without the intervention of the males, as, indeed, occurs in cases of parthenogenesis, where ova frequently become developed into perfect beings without the addition of the male element. On the other hand, it would seem that the sperm-cell is a portion of the organism cast off, as it were, at random, and in great profusion, to accommodate itself to new conditions of life, and being modified to bring back its newly-acquired qualities to the parent stock. Broadly stated, the germ-cell, or female, transmits the form and hereditary qualities of the race, while the sperm-cell, or male, introduces the variations which fit the race to survive under new conditions of life, the sex being determined by the greater vigour and maturity—or what is the same thing, the greater fitness for survival—of either parent. Where the conditions of life are uniform and constant, the germ-cell will predominate, and females will be produced in excess (as we see in the extinction of races and families by the failure of males); and where the conditions of life are variable or injurious to the race, the acquired vigour (in the struggle for existence) of the sperm-cell will predominate, and an excess of males will be the result.

It would occupy too much space to produce here the evidence which exists in support of my first proposition, that the process of reproduction in animals is identical in kind, and different only in degree from the process of budding in plants—a process which, though occasionally liable to inherent variations, is chiefly directed to the exact reproduction of the parental form and qualities. After examining the evidence on this subject in all its aspects, Darwin observes: "We may conclude that the several forms of gemmation and of fissiparous generation; the repair of injuries; the maintenance of each part in its proper state; and the growth or progressive development of the whole structure of the embryo, are all essentially the result of one and the same power."² And, again (page 362): "The difference between sexual and asexual generation is not nearly so great as at first appears.....The capacity of fertilisation by the male element seems to be the chief distinction between the ovule and a bud; and this capacity is not invariably brought into action, as is the case of parthenogenetic reproduction."

Throughout the organic kingdom we see on the one hand the anxiety, so to speak, of Nature to preserve and develop the germ-cell, while on the other we are constantly reminded of her lavish production and apparent wastefulness of the sperm-cell. Outside the human race (in this, perhaps, only in its civilised communities) there is hardly such a creature as an old maid, while the whole animal kingdom is teeming with bachelors, a state of things which shows the relative value, from a racial point of view, of the two sexes. In our biological speculations we are very apt, as Mr. Ruskin has told us, to forget the life and purpose of the individual, and think only of the race. "With respect to plants, as animals, we are wrong in speaking as if the object of this strong life were only the bequeathing of itself. The flower is the end or proper object of the seed, not the seed of the flower. The reason for seeds is that flowers may be, not the reason of flowers that seeds may be. The flower itself is the creature which the spirit (nature?) makes; only in connexion with its perfectness is placed the giving birth to its successor."³ Nevertheless, we see everywhere how serious Nature is in her efforts to continue the race, and how careless she is of the life of the individual, more especially of the male. In the plant the female organs form the axis of the flower, and the flower the apex of the branch. There is a stubborn clinging to hereditary characters in the female organs of plants, which contrasts strongly with the mutability of the stamens, and which enables botanists to use them with confidence as a basis of classification—a fact, by the way, which has not been sufficiently recognised by zoologists in their classification of the animal kingdom. Among insects the relative value of the germ- and sperm-cells is well marked. In a hive of bees several males exist, but only one is necessary, and this one dies the instant it has performed its sexual function, while the female becomes the parent of a numerous race, nearly the whole of which are imperfect females, buds, as it were, of the parent stock. Among the higher forms of animal life Nature protects the female from dangers by assimilating her colour to that of surrounding

objects, or by endowing her with protective mental qualities; while she renders the male conspicuous by greater size, brighter colouring, or bolder mental qualities, which expose him to external dangers, and excite rivalry, which excludes him from sexual life, or leads to his destruction. It is only in the human species, and this only in its civilised condition, that we find the two sexes of equal value, or inclining to the side of the male.

Confining our attention to the human race, and taking the living and stillbirths in various European countries, we find the proportion of the sexes is 143·3 males to 100 females. We also find that in the first births of a marriage the males are largely in excess. I found on examining Debrett's "Peerage" for 1877, that in 419 families, consisting of 1004 male and 1011 female children, the living birth-rate for the first year was 119 males to 100 females; while in Austria, among the general population, the first birth-rate was 110 males to 100 females. These figures show that there is not only an absolute excess of male births, but that the excess occurs at the earliest and most vigorous period of married life. In Norway it was found by M. Block⁴ that from the first to the sixth year of married life the proportions were 116 to 100, and from the seventh to the ninth only 107 males to 100 females.

But the sex rate is largely dependent on the relative maturity of the parents as well as on their vigour, the more mature parent being the most potent in determining the sex; the sex being the same as the most mature parent. The following well-known statistics, given by Hofacker and Sadler, are evidence of this. The figures show the proportion of male births to 100 females:—

HOFACKER.			
Father younger than mother ...	...	...	90·6
Father and mother of equal age ...	...	...	90·0
Father older by 1 to 6 years ...	...	...	103·4
" " 6 to 9 " ...	...	...	124·7
" " 9 to 18 " ...	...	...	143·7
" " 18 and more ...	...	...	200·0
SADLER.			
Father younger than mother ...	...	...	86·5
Father and mother of equal age ...	...	...	94·8
Father older by 1 to 6 years ...	...	...	103·7
" " 6 to 11 " ...	...	...	126·7
" " 11 to 16 " ...	...	...	147·7
" " 16 and more ...	...	...	163·2

As females attain to maturity two or three years earlier than males it is probable from the above table that, with a difference of age of three years in favour of the father and other things being equal, the number of the two sexes would be equal, or with a slight excess of vigour in one parent all would be of the corresponding sex. In the case of illegitimate births it is probable that the age and other circumstances are nearly the same in both parents, and consequently we find the proportion of 102·5 males to 100 females prevails, and this in spite of the excess of males which should result from first births.

The experiments on the impregnation of the ovum made by Quatrefages, Provost and Dumas, Newport, Kölreuter, and Gärtner, help us to understand not only how the sexes are determined, but how other physical differences and even some monstrosities are produced. The three French authors have shown, in the case of the teredo, that more than one spermatozoon is required to fertilise an ovule, and Newport, besides confirming these observations, has shown that when a very small number of spermatozoa are applied to the ova of batrachians they are only partially impregnated, and the embryo is never fully developed, although partial segmentation of the yolk does occur to a greater or less extent. The rate of segmentation is likewise determined by the number of spermatozoa. Gärtner found that even thirty grains of the pollen of a malva did not fertilise a single seed, but that when forty grains were applied a few seeds of small size were formed. Naudin fertilised a flower of *mirabilis* successfully with three grains of pollen, but of twelve flowers which were fertilised by two grains and seventeen flowers by one grain, only one flower of each lot perfected its seed; and the plants produced by these two seeds never attained proper dimensions, and bore flowers of remarkably small size. "From these facts," says Darwin, "we clearly see that the quantity of the peculiar formative matter which is contained within the spermatozoa

² Animals and Plants under Domestication, vol. ii., p. 359.

³ Queen of the Air, p. 76.

⁴ Traité de Stat., p. 344.

and pollen-grains is an all-important element in the act of fertilisation, not only in the full development of the seed, but in the vigour of the plant produced from such seed. We see something of the same kind in certain cases of parthenogenesis—that is, when the male element is wholly excluded; for M. Jourdan found that out of about 58,000 eggs laid by unimpregnated silkworms many passed through their early embryonic stages, showing that they were capable of self-development, but only twenty-nine out of the whole number produced caterpillars.¹⁵

In asserting that hereditary (physical and mental) qualities are transmitted by the female, and that variation and adaptability to new conditions of life are introduced by the male, I do not wish to imply that the germ-cell is not modifiable by external conditions, but only that it is subjected to fewer causes of variation, that it possesses a strong inherent disposition to resist change, and that it will be destroyed rather than accommodate itself to very marked changes in the conditions of life. We see instances of this in the destruction of the partially developed embryo by constitutional syphilis in persons otherwise healthy, and of the resistance of the embryo to other constitutional diseases, as, for instance, of acquired consumption, where it proceeds to full development in spite of the diseased parent.

The practical applications of this theory are sufficiently obvious. From the statistics which we possess it is probable that the births should be in the proportion of about three males to two females, and this number would be a typical family which would admit of the sacrifice—not necessarily the destruction—of one male, to accommodate the race to the ever-changing conditions of life, and to assure the constant accession of fresh vigour and maturity. The number of the living members of the families of the English peerage—where we find man living under the most favourable conditions of nurture and sanitary surroundings—gives an average of 4·8 children for each family, and the sexes are in almost equal proportions (one family of eleven girls makes the number of females very slightly predominate). But here, no doubt, there has been the usual destruction of males at birth—in this instance with no benefit, but absolute loss to the race,—and during childhood the greater destruction of boys than girls by children's diseases, which, with the single exception of whooping-cough, are all of them more fatal to male than female children.

As vigour is necessarily a relative term, it is difficult to see how this quality could be utilised, but it is obvious that persons living under very similar conditions of life should not marry. A literary man should not marry a literary woman, nor a tailor a seamstress; and the rule would apply to persons of the same temperaments and physique. The immense trouble, so to speak, which nature has taken to secure cross-fertilisation in the lower races of animals and in plants should guide man in his selection of a partner, and teach him the evils of in-and-in breeding, which is not necessarily a matter of blood relationship, *but of the similar conditions of life*. With respect to maturity, it is a great error to believe that puberty in either sex is a sign of fitness for marriage. Throughout nature we see that growth and reproduction cannot go on together beneficially, reproduction being, as I have endeavoured to show, a diversion of growth, or development in a new direction—namely, from the individual to the race. Men do not cease to grow till the age of from twenty-one to twenty-five years, and women till the age of from eighteen to twenty, according to the good or bad nurture they have been subjected, the best nurtured attaining maturity first. It is obvious that these respective ages are the very lowest at which marriage should take place, and we have statistics to prove that there should be a considerable difference in favour of the age of the husband if male progeny is desired.

Probably the best way of increasing the male birth-rate will be to direct all our energies to prevent the great loss of male life at the moment of birth, amounting to about 140 to 100 females. This is being done in a slight degree by the great improvements in the art of midwifery; but the mischief lies in the disproportionate size of the male fœtus and the mother, and it is impossible to estimate the great loss which the race sustains in superior physical and mental qualities by this unceasing destruction of its finest products. At birth, and in children born alive, the average length of male infants is 19·34 in., and of female infants, 18·98 in.; while their weights are respectively 7·55 lb. and 7·23 lb.—

the difference in height being only 0·35 in., and in weight 0·32 lb., or about the third of an inch, and less than a third of a pound weight. But these figures are a mere register of the size of the female pelvis, and we possess no data of the relative size of still-born children. The remedy for this waste of valuable life is to be found in the direction of the improved development of girls by physical education, and by a more careful matching of the sexes in marriage. The average stature of Englishwomen is from 5 ft. 2 in. to 5 ft. 3 in., and of men about 5 ft. 7 in. to 5 ft. 8 in., the difference between the two sexes being from four to five inches; and as stature carries with it other relative proportions of the body, it is probable that if these limits were observed all through the scale of heights, there would be fewer still male births. It is probable, also, that the intellectual struggle for existence going on among men at the present day is causing the development of larger heads in male children; and the recent impetus given to the education of girls and the employment of women in intellectual occupations is adding to this difficulty, and if it does not end by producing sterility (as is probable), or of female children only (as is still more probable), it must tend to the destruction of more and more males at the moment of birth. It is obvious that whether we consider the health and happiness of the individual, or the future prosperity of the race, the healthy physical development of girls is of the first and supreme importance. In the sense in which we say the boy is father of the man, we may also say that the girl is the mother of the race; for to her is entrusted not only the accumulated hereditary characteristics of our ancestors, but the means of transmitting them, and, indirectly, of acclimatising and accommodating the race to new and varying conditions of life.

Bolton-row, Mayfair, W.

FIVE YEARS' SURGICAL WORK IN THE CARDIFF INFIRMARY.

BY ALFRED SHEEN, M.D.,

SURGEON TO THE INFIRMARY.

(Concluded from p. 766.)

Abscesses.—This is not an interesting class of cases, and I fear that my treatment has been altogether of a too desultory and routine a character. The antiseptic treatment of such cases seems to offer better prospects of success than I have hitherto attained to, and in future I shall give it a more extended and persistent trial. One case of lumbar abscess was

aspirated, and did well; twelve ounces of pus were drawn off, and the patient was discharged cured two months afterwards. The breast case was sent in as one of tumour for removal, but the history and appearance clearly pointed to its being a chronic abscess. Iodoform 1 to vaseline 15 was applied for some weeks, and the induration left by the abscess disappeared.

			1 6	2 0		3 6

⁵ Animals and Plants, vol. ii., p. 364.

The lymphadenoma was extensive, in the neck chiefly, with only a three months' history. The patient died of exhaustion fourteen months after his discharge. The thyroid tumour was of the size of an orange. The patient was admitted as an urgent case, suffering from sudden attacks of dyspnoea, and in one of these he died, twenty-four hours after admission.

CANCER.

	Under ten.	Under twenty.	Under forty.	Under sixty.	Over sixty.	Totals.
	M. F.	M. F.	M. F.	M. F.	M. F.	M. F.

	5	1	7	3	6	4
	18	8				

Many of these cases were operated on, and one is accounted for under another heading. One case of cancer of the tongue and one of the upper maxilla were deemed too extensive to be interfered with, and were therefore discharged. The case of cancer of the neck involved deep structures, and the patient died suddenly from hæmorrhage.

HERNIA.

5	4	Inguinal	—	—	4 0	2 0	1 0	7 0
8	7				4 1	2 0	1 3	7 4

Of these eleven cases of hernia eight were operated on, and seven of these died, a most lamentable result, which I have commented upon under the heading "Operations." Of the remaining three cases, one was a large scrotal hernia in a patient aged thirty-two, which had been down three days without his being able to return it, as he had previously done; and another was a small strangulated femoral hernia, complicated by the existence of a previously existing irreducible hernia, in a female aged thirty-seven. The strangulated portion was returned.

SPINAL DISEASE.

Angular curvature ..	4 0	0 2	—	—	—	4 2
	4 0	1 2	2 0			7 2

Most of the cases of spinal disease were admitted before Sayre's treatment came prominently before the profession. In two cases, however, a boy aged eight, and one aged four and a half, with dorsal angular curvature, the jacket was applied with marked relief, the children being from that time perfectly free from pain, and able to run about without any difficulty, their previous condition being just the opposite of this. This was in 1878. Previous to the advent of the plaster jacket the treatment of these cases was in the highest degree unsatisfactory, whilst now it is almost everything that could be desired, and many cases have the jacket applied and are even treated as out-patients. I prefer the poroplastic jacket for cases of lateral curvature.

Varicose: leg ..	—	—	0 1	—	—	0 1

In the class "Arteries" the case of thrombus was a sequel of scarlet fever. It was in the femoral artery close to the groin. It is noticed under the heading "Amputations." The case of aneurism in a female I had seen in consultation two months previous to admission, and advised her immediate removal to the infirmary for treatment. I was interested about the case, as I was anxious to try the effect of pressure by means of the elastic bandage, as suggested, I believe, by Dr. Reid, R.N., but I heard nothing more of her till she was admitted. She had passed through several hands (surgical). The sac had ruptured, and there was now nothing left to be done but to remove the limb. Amputation was performed, and the patient did well. The second case did remarkably well (*vide* "Operations").

The case of varicose veins in the leg was in a woman aged forty, of seven years' duration, accompanied by much swelling and severe pain. She was treated by rest in bed, on an inclined plane, for forty-four days, when she was fitted with an elastic stocking and discharged.

There is no special ophthalmic department in our infirmary, and this will account for the comparatively large number of eye cases admitted under my care, the greater number of which are of no particular interest. One case of acute conjunctivitis occurred in a previously blind eye, and rapidly subsided under ordinary treatment—namely, rest and from eight grains to an ounce of collyrium of alum.

The case of purulent ophthalmia was in a boy aged three, the result of contagion, and very severe. One eye was already lost before his admission, and the other was saved only by the very frequent and regular application of a twenty-grain collyrium of alum. This treatment changed the aspect of the case in twenty-four hours, and the eye rapidly recovered. (This child had neglected eczema of the whole scalp. It had been under intermittent treatment for many months at home without any permanent benefit, but six weeks of persistent treatment "under orders," in the infirmary, completely cured it. Glycerine of tannin was used locally.) The case of granular lids of two years' duration, not very severe, was apparently cured by the careful application of lapis divinus. The operation-cases in this class are noted under the heading "Operations."

RECTUM.

	Under ten.	Under twenty.	Under forty.	Under sixty.	Over sixty.	Totals.

Stricture ..	—	—	—	0 1	—	0 1
Obstruction ..	—	—	—	1 0	—	1 0
	1 2	3 1	2 1			6 4

The case of obstruction was obscure as to its cause, but complete. The index-finger introduced into the rectum as far as it would go impinged on something which gave one much the same feeling that the os uteri does, and on its withdrawal a small clot of dark blood was adherent to it. Nothing had passed for thirteen days previous to the operation of colotomy in the left loin, which was performed (for the first time in this infirmary), and the patient was discharged in twenty-five days with an artificial anus, which he said gave him no trouble or annoyance. He was a healthy-looking man, with no appearance of malignant disease, and there was no evidence of the presence of a tumour on careful examination of his abdomen. He was discharged on

August 9th, 1879, and on December 2nd he was readmitted on account of the contraction of the opening in the loin, so as only to admit a No. 6 gum elastic catheter. A sponge-tent left in for twenty-four hours completely relieved this state of matters, and he was discharged. On Dec. 21st he passed flatus per rectum for the first time since the operation, and later on the same day he passed fæces. Next day he had three motions *per vias naturales*, all semi-fluid and very dark, almost black, but no pus or blood. I saw this patient recently (Nov. 1880). The opening is still patent in the loins, but his bowels are relieved naturally. He has been losing flesh somewhat lately, and complains of some pain in the seat at times when sitting, and says he can feel something like a bone close to the anus. On examining him I found a hard epitheliomatous tumour, the size of a large nut, just inside the anus, posteriorly and a little to the left, whilst anteriorly and slightly higher up the rectum is a thickish diagonal band of new deposit about a finger's breadth, which is evidently lessening the calibre of the bowel. He is kept under observation. Previous to the operation this case was interesting as indicating the uselessness and even danger of giving purgatives in such cases, and the great value of puncturing the bowels through the abdominal wall with a small trocar and cannula for the relief of tympanites.

The hæmorrhoids were mostly external, and they were removed by the knife or scissors. The fistula cases were all operated on and did well. In three cases a sharp-pointed bistoury was pushed gently through the fistula on to the finger inserted in the rectum, and then brought down. I prefer this mode of operating to any other, as being the simplest, and there is no fear of wounding one's own finger if ordinary care be exercised. The case of stricture was not complete, was malignant in its nature, and was not interfered with; the patient, being discharged, disappeared from observation.

URINARY ORGANS.

	Under ten.	Under twenty.	Under forty.	Under sixty.	Over sixty.	Totals.
Chronic cystitis	1	1	1	1	1	5
Prostatic disease	2	2	1	1	4	10
Stone	1	1	1	1	4	4
Incontinence of urine ..	1	1	1	1	4	4
Stricture	7	11	1	1	19	19
Phimosis	1	1	1	1	4	4
Hydrocele	3	3	1	1	8	8
Orchitis	1	1	1	1	4	4
Hypospadias	1	1	1	1	4	4
	1	2	13	17	5	38

Of the 38 cases of disease of the urinary organs here tabulated, one-half were cases of stricture of the urethra. All the patients were males. The cases of enlarged prostate were chiefly in old men, and were mostly admitted on account of retention of urine; by rest in bed, passing a catheter, a simple diet, and in some cases a little medicine, this symptom was soon sufficiently relieved to allow of the patient's discharge. The stone cases were two in number. In one patient, aged nineteen, lateral lithotomy was performed in the usual way, and a mulberry calculus extracted, weighing 3 drs. 45 grs., and measuring 1 in. by 1½ in. The size of the stone was ascertained previous to the operation by the aid of the lithotrite. Should such another case come under my care, I should be inclined to practise Bigelow's operation of litholapaxy. The other case was in a patient, aged twenty-eight. There were two phosphatic stones. Lithotripsy was performed, the stones being crushed on nineteen different occasions. Weight of detritus ½ oz. Both patients did well. One case of prostatic disease proved to be an abscess in that gland, for on introducing a catheter for the relief of the retention, exit was given to a considerable quantity of pus, with great relief to the patient. The cases of stricture were mostly organic; some few were traumatic, and some spasmodic. The organic and traumatic were all treated on the principle of gradual dilatation, and the patient, before leaving the infirmary, was taught to pass an instrument for himself, was cautioned to pass it from time to time, and was told of the incurable nature of his complaint. If this were systematically done in all our hospitals, and if the patients could be induced to take that constant watchful care of themselves which is needed, we should, I think, seldom have these cases in hand a second time. I do not think the nature of spasmodic stricture is always sufficiently clearly recognised in general practice. In most of these cases which have come under my notice in hospital, fruitless and continued efforts had previously been

made to pass a catheter into the bladder, with no result but hæmorrhage and pain; and so constant in my hands have been the good effects of rest in bed, the administration of chloral or morphia, and the avoidance of all instrumental interference, that I have adopted this line of practice as a piece of routine in such cases. One case of stricture was the result of amputation of the penis. The case of phimosis was in a married man, aged thirty, the father of five children, who only sought relief on account of inflammation and thickening of the edge of the prepuce. In two cases of hydrocele a radical cure was attempted, and was successful.

CASE 1.—Aged fifty-four; five months' duration; cause unknown; right side; 12 fl. oz. drawn off, and half a drachm of tincture of iodine, with one drachm of water, injected into the sac. The patient was in bed six days, and had neither pain nor swelling.

CASE 2.—Aged fifty-six. Similar treatment and results.

In the case of hypospadias there was an opening on the under-surface of the penis just beyond the prepuce, about the size of a pin's head, and the urethra was impermeable from that point onwards. It was not considered advisable to interfere by way of operation.

The following cases, which were also admitted under my care, I have been unable to classify under any of the previous headings:—

Infantile paralysis	0	1	—	—	—	—	—	—	0	1
	3	2	2	3	1	3	1	0	8	11

Of these cases the syphilitic were cured by large doses (ten grains three times a day) of iodide of potassium. The case of deafness was chronic and incurable, the middle ear being completely destroyed. One case of chronic bubo was dispersed by repeated (three) blisters. The case which is called nervous mimicry was an obstinate case of hysteria. The patient, a female aged twenty-four, had in previous years been from time to time under my care in the outpatient department, and was now admitted supposed to be suffering from some disease of her right knee and leg. She stated that she had been unable to get about without crutches for some months. The muscles of the right leg were flabby and smaller than those of the left from want of use, and the knee apparently larger than its fellow. She declared she could not bend her right knee, and refused to do so, but on one occasion, after she had been asleep, her knee was observed to be bent (the usual position of the limb being straight), and she called a nurse to straighten it for her, as she said she was unable to do so herself. Galvanism of the muscles of the leg was ordered, but on the appearance of the battery in the ward she asked for her discharge, stating that she felt much better. A few months previous to her admission I saw her walking about without any aid, and three months after her discharge she was observed walking along the street, with only a very slight limp, and without any support.

The ingrowing toenail was removed under ether spray, but the patient complained severely of the pain of the latter. The case of infantile paralysis was much improved by a month's daily faradisation of the affected muscles.

This is but a brief survey of about one-half of the surgical work of our infirmary during a period of five years. I might have entered into further detail on many points, but my paper has already exceeded the limits I proposed at its commencement.

Cardiff.

FLATULENT DISTENSION OF THE COLON.

By R. W. BURNET, M.D., M.R.C.P.,
PHYSICIAN TO THE GREAT NORTHERN HOSPITAL.

WHEN one meets with patients suffering from a sense of fullness and discomfort in the epigastrium, with more or less pain in the right or left hypochondriac region and in the back, or, as they often say, "through to the back," one generally finds they have come to the conclusion that their liver is at fault, and they have had recourse to the usual popular measures for reducing to order the offending organ.

In some exceptional instances, no doubt, the patient is right in throwing the blame upon the liver, for in organic disease of that organ we do undoubtedly get pain in the back, between the scapulae, in the right scapular region, and so forth. If, however, we exclude cases of impacted gall-stone, where the pain often takes curious and anomalous forms, and may be referred to one or more points remote from the hepatic region—cases of malignant disease and of abscess, cases of extreme congestion, causing marked distension of the capsule, and of advanced cirrhosis where the hepatic substance is compressed by a greatly contracted capsule—excluding these cases I venture to think that the liver is more blamed as the cause of pain, and even as the source of discomfort, than it deserves.

Many of the indefinite backaches and pains in the side complained of by women, of the poorer classes especially, are, no doubt, due to uterine disorders and displacements, and although to say that every woman has a pain in her back may seem to be a loose way of talking, yet I have heard the remark made by a physician of large experience, and am convinced that applied to hospital patients, at least, it is nearer the truth than might at first sight be supposed.

Upon the consideration of these hepatic and uterine disorders I do not mean here to enter, but what I wish to show is that in a large proportion of cases the source of the trouble lies in the colon—in those cases, namely, where, on examination, we find that the large bowel has become distended in some part of its course, and by pressure on the surrounding organs and structures causes the symptoms of which the patients complain.

Assuming then for the moment that such a condition as flatulent distension of the colon does exist apart from the distension from stricture caused by the cicatrisation of ulcers, by malignant disease or by pressure from without, what are the causes that lead to it? In general we may say that everything which tends to bring about a relaxed and atonic condition of the mucous and muscular coats of the bowel is a predisposing cause. The patients are for the most part women, and they are women who are more or less sedentary in their habits and whose tissues are soft and flabby; they have usually suffered at times from gastrointestinal catarrh, from irregular action of the bowels and from constipation, for which they have been in the habit of taking quantities of aperient or antibilious pills and other purgative medicines. In some the excessive use of brown bread of the coarser sorts seems to act unfavourably on the mucous membrane, and in one well-marked case in a gentleman it seemed to follow a prolonged course of hydropathic treatment where, in addition to the use of all varieties of hot and cold baths, the patient had for some time worn compresses round the abdomen. Such agents as these bring about an irritable condition of the mucous membrane, together with a want of tone in the walls of the bowel. The site of the pain I think throws some light on the immediate cause. I have said that it is very frequently in the right or left hypochondriac region—i. e., in the parts of the bowel preceding its sharp curves, the hepatic, the splenic, and the sigmoid flexures. In women the configuration of the body and the mode of dressing tend largely to impede the free movements of the parts upon which the tight garments press, and looking at the colon as a tube, we see how largely it will be affected by these restrictions. An indiarubber tube through which a stream of water is passing will, if sharply bent, dilate and even burst before it allows the water to pass. Again, any lodgment of fæces or other irritating cause may set up spasmodic contraction, and if this occurs, as is most probable, at a part where the calibre of the bowel is

already narrowed, the consequence is distension behind the site at which the impediment exists.

Coming now to the symptoms which characterise this condition: the patient looks worn, and he may even be depressed and haggard; the complexion is muddy and wanting in that clearness which characterises perfect health; the tongue is whitish or dry, and coated, often marked at the edges by the pressure of the teeth; the pulse is natural in frequency, but soft, compressible, and easily excited; palpitation and "fluttering of the heart" are frequently complained of, accompanying a sense of fullness and weight which they experience sometimes after meals. Along with the more distinctive symptoms, there are the general ones of languor, headache, nervousness to a greater or less degree, and usually very marked depression. Here I would notice in passing the remarkable association that there is of mental depression with affections of the lower bowel. Whether the relation is sufficiently close to warrant its receiving the name of "colonic melancholia" I am not prepared to say, but I think it cannot be denied that the depression of spirits which accompanies disorders and diseases of the colon and of the rectum is out of all proportion to the extent of the mischief. A recent writer on constipation,¹ speaking of the effects of that condition on the nervous system, looks upon it as the result of blood-poisoning from absorption of some part of the faecal matter, and no doubt this takes place in cases of long-standing constipation; but from cases of the nature of those I am now considering, it is evident that a further element is involved. Why is a patient with flatulent distension of the colon utterly dejected, while one with lumbago is howling every time he moves, and then laughing at himself for crying out? That there is an intimate connexion between the state of the bowel and the state of the mind I feel sure, but am unable to offer any satisfactory explanation of the fact.

Patients who are the subjects of the affection now under consideration are liable to sudden attacks. At one time, as already mentioned, it is a heart attack, by which I mean more than a mere fit of palpitation. They have great discomfort in the cardiac region, and feel "as if the heart were going to stop." At other times it is an attack of colicky pain usually in some part of the colon. Indeed, in describing the different places at which at one time or another they have had these pains they often point out exactly the course of the colon, commencing below the hepatic flexure, and following it across the epigastric to the left hypochondriac region. In their depressed state a sharp attack of pain of this kind alarms them, and they conclude that they are suffering from inflammation of the bowels. Except the pain there is, however, no symptom common to this condition and to enteritis, and even the pain is quite dissimilar in character. It is variable; it is more or less widespread; it is not only not increased, but is usually rather relieved by pressure; it is temporarily relieved by the action of the bowels, especially if some flatus be got rid of at the same time; it is shifting, or at least somewhat movable, for patients say that they "have to hold their side," and that when they do so the pain is lessened or shifts to some other part of the bowel.

Physical examination reveals a distended colon. On palpating the abdomen we have in some part of the course of the colon a feeling of resistance, and by careful handling we may make out the rumbling of flatus under our fingers, with sometimes the jumbling of fluid in the distended bowel. On percussion we get a tympanitic note over an area more or less extensive, and corresponding to the amount of distension. Exceptionally we find slight tenderness, but usually even firm pressure causes no uneasiness.

In considering the treatment of the affection I am now speaking of, we must have regard to the causes that have been at work in bringing it about, and to the habits of diet and mode of life in each case. If we can put our finger on the cause and remove it, we shall be far advanced in the treatment. We must find out whether the patient is in the habit of drinking much tea or large quantities of hot fluids, and if so we must considerably reduce the supply. The use of tea has a marked effect in aggravating the distension and discomfort, so much so that where the tendency to this state of bowel is strong, tea taken in any quantity will be almost certain to bring on an attack of pain. Patients have sometimes found this out for themselves, and have given up the use of tea. We must limit the diet to simple easily digested

¹ THE LANCET, Feb. 14th, 1880.

food, given in three or four small meals a day. We must exclude tea, coffee, malt liquors, and strong wines, also raw vegetables, pastry, sweets, and ices. The quantity of liquid taken with food should also be limited to one breakfast cup or less with breakfast, half a pint in the middle of the day, and the same quantity with the evening meal. With the two latter we may allow in the water either a glass of claret or of dry sherry, or a half glass of spirit. If there is much tendency to constipation the simple remedy of a half tumblerful of fresh cold water, sipped the first thing in the morning and the last thing at night, will often aid the action of the bowels, and it seems to supply at a time when it does not harm the quantity of fluid required by the system. A daily natural action of the bowels should, if possible, be obtained, and this may often be gained by enforcing the habit of soliciting their action at a fixed time every day. Cold or tepid sponging followed by vigorous friction will also be useful. As far as drugs are concerned, the treatment is very much what we should adopt in ordinary colic and dyspepsia, at the different stages of these two affections. If there be much pain when we see the patient, and the condition be purely a temporary one, probably we shall most easily and speedily attain our end by giving a dose of castor oil, with or without a few drops of laudanum, and following it up, if necessary, by an enema. In less urgent circumstances we may give at night an alternative and aperient pill of blue mass, with colocynth and hyoscyamus, and in the morning an aromatic rhubarb draught. Such measures as these are calculated to give speedy relief for the time being, but we must endeavour to obviate the recurrence of the attacks, and we should probably have recourse to the good old-fashioned mixture of soda and gentian with aromatic spirits of ammonia, or to bicarbonate of potash with tincture of nux vomica and infusion of calumba, given twice or thrice daily, two hours after food. Sometimes ten drops of the tincture of nux vomica in a little water, three times a day, will answer well. Following this, we may give a pill of reduced iron with pepsin and extract of nux vomica and of belladonna with food twice daily.

In hospital practice, probably, the readiest and most useful medicines at this stage are the ordinary aloes and iron and the aloes and assafoetida pills. Finally, with a clean tongue and free secretion we should give a mixture of hydrochloric acid and extract of bark between meals twice a day, or the citrate of iron and quinine with a few drops of liquor strychniæ. When the mucous membranes are free these tonics undoubtedly bring about a healthier tone of the digestive organs and give excellent results.

Nottingham-place, W.

AN IMPROVED METHOD FOR EXCISING THE WRIST-JOINT.

By W. ROGER WILLIAMS, L.R.C.P.L., M.R.C.S.E.,
SENIOR HOUSE-SURGEON, ROYAL ALBERT EDWARD INFIRMARY, WIGAN;
LATE DEMONSTRATOR OF ANATOMY AT UNIVERSITY COLLEGE;
AND FORMERLY AT THE MIDDLESEX HOSPITAL.

It is not so long since Malgaigne wrote of excision of the wrist joint, "une opération déplorable, et qu'il est temps de rayer absolument de la pratique." But all this has changed now—thanks to the labours of Mr. Lister,—and the great advantages to be derived from the operation are generally recognised. Yet it is seldom performed. This, I believe, is mainly due to the complicated procedure usually adopted. "It has," says Liston, in the introduction to his work on Practical Surgery, "been well and truly remarked by the celebrated Desault, that the simplicity of an operation is the measure of its perfection." In endeavouring to carry out this injunction I have planned an operation by which the dorsal incision is altogether dispensed with, and the tendons are separated with less disturbance than was formerly possible—advantages, as I think, of considerable importance, since the large wound in the midst of the tendons is thus avoided, and consequently no cicatrix is left to which the adjacent parts become matted, as so often happens after the operations of Lister and Langenbeck. Another point on which I lay great stress is the preservation of the trapezium. The subsequent utility of the thumb, and indeed of the whole hand, is greatly enhanced by this.

Whatever proceeding may be adopted, the removal of this bone is always a matter of some difficulty; and experiments on the dead body have convinced me that the radial artery seldom escapes division. It has been usual to describe the intercarpal synovial membrane as common to all the carpal bones except the pisiform, and this has led to the idea that in disease all the bones must be pretty equally affected. But according to M. Tillaux¹ the intercarpal synovial membrane consists of three separate sacs; and the trapezium is connected with only one of these—viz., that one which is chiefly special to the articulation of the scaphoid with the trapezium and trapezoid. It is hardly necessary to mention that the synovial membrane between the trapezium and the first metacarpal bone is special to that joint.

Thus there is reason to believe that a careful examination of cases suitable for excision will show that the trapezium is less frequently diseased than might be expected. In all cases an endeavour should be made to ascertain its condition before commencing the operation; and if diseased the gouge should be used.

To commence the operation the hand should be placed prone. In this position it is easy to make out the following landmarks:—The inner border of the fifth metacarpal bone, which is immediately external to the projecting mass of the muscles of the little finger; following this upwards we come to a small, but perfectly obvious, projection, due to the apex of the cuneiform; still higher up is the much larger prominence of the head of the ulna, and a little in front of this is its styloid process. Speaking in general terms, the incision may be said to pass along the back of the wrist near its inner border (see Fig.). The point of the knife is

entered over the tendon of the extensor carpi ulnaris, at a short distance above the head of the ulna. The incision is prolonged downwards between the head and styloid process of the bone, over the apex of the cuneiform, and thence along the inner border of the fifth metacarpal bone, at the middle of which it ends. In the upper part of the wound the tendon of the extensor carpi ulnaris must be laid bare, at its middle the pisiform is to be disarticulated, and in its lower part the opponens minimi digiti should be detached from the metacarpal bone. The extensor carpi ulnaris tendon is now to be separated from the base of the metacarpal bone, and to be freed from the ulna as far as may be necessary. The articular surfaces of the ulna and the fifth metacarpal bone are then to be sawn off. The next step is to cut off the unciform process with the bone forceps. It is then easy to raise the soft parts from the front of the wrist, with scarcely any injury to the synovial sheaths. The tendon of the flexor carpi radialis lying in the groove of the trapezium is not to be disturbed. The articular surfaces of the three middle metacarpal bones are now to be cut off; and the trapezium must be separated from the trapezoid and scaphoid. The latter part of the proceeding may be done most conveniently by introducing the blades of the bone forceps between the first and second metacarpal bones, and cutting upwards towards the outer part of the lower end of the radius. The soft parts being held up by the copper spatula, a small jaw saw—one with a strong back, the breadth of whose blade does not quite equal the thickness of the lower end of the radius—should then be applied to the front of this part of the bone, just above its articular surface. The section is not to be quite complete: the dorsal lamina should be broken through. A few touches with the knife suffice to separate the detached extremity from the dorsal tendons, with scarcely any injury to these. There is nothing now to prevent the removal of the excised bones.

Of course, if the parts are much altered by the disease, it

¹ Anatomie Topographique. Deuxième édition, p. 541

will often happen that a more irregular proceeding will be adopted.

The trapezium, pisiform, and the unciform process should be left alone unless they are diseased.

The after-treatment is that recommended by Mr. Lister; and the parts divided are the same as in his operation.

Wigan.

ON THE ASSOCIATION OF AFFECTIONS OF THE THROAT WITH ACUTE RHEUMATISM,

By J. KINGSTON FOWLER, B.A., M.B.,

ASSISTANT-PHYSICIAN AND PATHOLOGIST TO THE MIDDLESEX HOSPITAL,
ASSISTANT-PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION.

I HAVE for some time past made it a rule in all cases of acute rheumatism which come before me to inquire carefully for any history of tonsillitis or catarrh of the pharynx having preceded the attack. I was led to do this by a remark from Dr. Garrod, F.R.S., when he was attending me for a severe attack of rheumatic fever in the winter of 1874.

A month before my illness I had a sharp attack of acute tonsillitis, and Dr. Garrod told me he had noticed that the two affections were not uncommonly associated. I have lately kept notes of all cases of acute and subacute rheumatism, and find that in a very large proportion the attack has been preceded at an interval varying from nearly a month to a few days by some affection of the throat. It may be a simple catarrh, but in many cases it takes the form of acute inflammation of the tonsils. Without at present being able to give an exact percentage of cases presenting this premonitory symptom, I think I should not exaggerate if I were to put it at 80 per cent. Dr. Garrod tells me that further experience has confirmed his first impression, and he is disposed to put the figure quite as high as I have stated above. Trousseau¹ has described a "rheumatic sore-throat," evanescent in character, and preceding by a few hours the articular manifestations, but he does not mention tonsillitis among the premonitory symptoms, and his observations have apparently been overlooked by the authors of our text-books on medicine.

In some cases the throat and joints are affected simultaneously; and I have also met with cases of relapse from acute rheumatism where the primary attack and the relapse have both been preceded by throat symptoms. I believe this sequence of events is of too frequent occurrence to be explained on the hypothesis of a merely casual connexion—i. e., that a person having, through a chill, or some other cause, had a "sore-throat," further exposure has brought on an attack of rheumatic fever. Tonsillitis is a very common affection, and in many cases is not followed by rheumatic symptoms. Nevertheless I believe that not unfrequently it is an early manifestation of the rheumatic diathesis, and that by so regarding it we may prevent the further development of that tendency. This sympathy is not limited to rheumatism, for it is a matter of common experience that scarlet fever and measles, diseases which are almost invariably ushered in by severe affections of the throat, are frequently followed by the so-called "rheumatic" affections of the joints; by acute arthritis; and even occasionally by pyæmia.

Mr. Hilton² was of opinion that in these cases some antecedent injury or over-fatigue of the joint had deteriorated its vitality, and that the depressing influence of the disease led to inflammation of the joint, which appeared after the fever had subsided. I think, however, that these affections of the joints following acute fevers are of too common occurrence to be thus accounted for. Bearing in mind the extreme prevalence of valvular affections of the heart, which, as is well known, can in the young be generally traced to fibrinous vegetations having formed on the valves during an attack of rheumatism, it must be admitted that any means which enable us to foresee and possibly ward off a disease causing agonising pain, and often leaving behind it an irreparably damaged heart, are of great value. Sir William Jenner has shown the importance of early treatment in enteric fever, and it is not less important in acute rheumatism. The

cardiac complications usually appear early in the case, and when once the patient has been got to bed the danger from that source is much lessened. I am now so firmly convinced of the truth of these facts that I think far more seriously of seemingly trivial throat affections, and in all such cases advise my patients to be on their guard against the slightest subsequent exposure to cold, and to seek medical advice on the first appearance of pain in the limbs or joints. I believe that in this way I have in two or three cases, by a timely administration of anti-rheumatic remedies, such as the salicylates, succeeded in warding off what might have proved a severe attack of acute rheumatism. One can only speak with great reserve on such a point, as it is impossible to say whether or no an attack was imminent. Hospital out-patient cases are so soon lost sight of, and it is a matter of such difficulty to follow them up, that the opportunities for prophylactic treatment are far fewer than in private practice.

The following are very brief notes of twenty cases of acute rheumatism which have quite recently come under my observation. The first six cases were under the care of Dr. Cayley at the Middlesex Hospital:—

CASE 1.—Thomas C—, aged thirty. Aug. 21st, 1880: Had a sore-throat, so severe that he could scarcely speak.—Sept. 6th: Admitted for acute rheumatism. Tonsils enlarged and mucous membrane of pharynx injected.

CASE 2.—Frederick S—, aged twenty-one. Sept. 24th, 1880: Had sore-throat, pain in swallowing, and coughing. Admitted Oct. 9th for acute rheumatism. Tonsils enlarged, uvula and pharynx injected.

CASE 3.—Eliza J—, aged twenty-four. On August 28th, 1880, had sore-throat and difficulty in swallowing. Admitted September 11th for acute rheumatism.

CASE 4.—Kate L—, aged twenty-one. Had sore-throat, not severe, when pains appeared. Admitted for acute rheumatism on September 20th. During convalescence she had an attack of tonsillitis; no return of rheumatic symptoms before discharge.

CASE 5.—Clara H—, aged seventeen. On September 25th, 1880, had a bad sore-throat, with pain in swallowing. Was admitted for acute rheumatism on October 16th. Tonsils enlarged, and mucous membrane of fauces injected.

CASE 6.—Thomas L—, aged twenty-seven. On October 12th, 1880, had a sore-throat.—Oct. 19th: Admitted for acute rheumatism. Tonsils enlarged, uvula elongated, mucous membrane of pharynx injected.

The four following cases were under the care of Dr. Coupland, in the Middlesex Hospital:—

CASE 7.—August M—, aged thirteen. August 11th, 1880: Attended as out-patient under my care at the Middlesex Hospital for acute tonsillitis.—August 26th: Was admitted for acute rheumatism and endocarditis.

CASE 8.—George S—, aged twenty. Four years ago had acute rheumatism preceded by sore-throat.—Sept. 16th, 1880: Had severe sore-throat.—Sept. 28th: Rheumatic pains with effusion into knees, ankles, and nearly all joints of left hand.—Oct. 2nd: Admitted for acute rheumatism and endocarditis.

CASE 9.—Louisa A—, aged eighteen. Out-patient under my care for some weeks for enlargement of cervical lymphatic glands.—Aug. 28th, 1880: Had an attack of acute tonsillitis.—Sept. 11th: Complained of pains in knees.—Sept. 25th: Admitted for acute rheumatism and endocarditis. Relapse on Oct. 10th, accompanied by fresh attack of tonsillitis.

The following cases have been under my care in the out-patient department:—

CASE 10.—Henry F—, aged thirty-three. Five years ago had acute rheumatism; laid up for a month. Had severe sore-throat a week preceding the attack.—Oct. 9th, 1880: Slight pains in limbs.—Oct. 16th: Had acute tonsillitis, followed in a few days by return of pain.—Oct. 23rd: Complained of severe pain in all his joints.

CASE 11.—George L—, aged fourteen. Whilst out-patient, suffering from bronchitis, had on Oct. 23rd, 1880, a severe attack of acute tonsillitis, followed in three days by pain in nearly all joints.

CASE 12.—Elizabeth A—, aged nineteen. Oct. 7th, 1880: Had acute tonsillitis, with enlargement of glands at angles of jaw on both sides.—Oct. 28th: Came as out-patient. Tonsils enlarged, right shoulder fixed and very painful, pain in limbs and back.

CASE 13.—Walter T—, aged eight. Sept. 7th, 1880: Had a bad sore-throat with pain and difficulty in swallowing.—

¹ Clinical Medicine. Sydenham Soc. Trans., vol. ii., p. 466.

² Lectures on Rest and Pain.

Oct. 2nd: Complains of pains in nearly all joints. Temperature 101·8°. Tonsils enlarged.

CASE 14.—Harriet E—, aged twenty-seven. Oct. 27th, 1880: Had acute tonsillitis, followed in a few days by pains in nearly all her joints.

CASE 15.—Margaret M—, aged fourteen. Aug. 24th, 1880: Had sore-throat and pain in swallowing.—Aug. 28th: Pain in nearly all joints; tonsils inflamed and enlarged.

CASE 16.—Selina C—, aged twenty-eight. Oct. 7th, 1880: Had acute tonsillitis, followed on Oct. 16th by pain in the left shoulder.—Oct. 21st: Complained of severe rheumatic pains in joints. Tonsils enlarged; uvula adherent to left tonsil.

CASE 17.—Dorothy A—, aged twenty-eight. Oct. 17th, 1880: Throat-sore; pain and difficulty in swallowing.—Oct. 22nd: Had acute rheumatism; metacarpo-phalangeal joint of left hand enlarged and painful; left shoulder also painful.

CASE 18.—Bertha N—, aged four. Mother states that she had a sore-throat last summer, followed in one month by pains in her limbs.—Oct. 14th, 1880: Complained of sore-throat.—Oct. 16th: Pain in both arms and in knee-joints.

CASE 19.—Eliz. B—, aged twenty-eight. Had a rigor on Oct. 11th, 1880; on the following day acute inflammation of the tonsils commenced; a few days subsequently pains appeared in the limbs and joints.

CASE 20.—Jane M—, aged forty-two. Sept. 20th, 1880: Had sore-throat, which was better in a few days.—Oct. 14th: Had bad sore-throat.—Oct. 21st: Severe pains in right shoulder and arm. Laid up for ten days subsequently with acute rheumatism.

Clarges-street, Piccadilly.

THE CURE AND CARE OF THE INSANE.

By ROBERT BOYD, M.D., F.R.C.P.,

LATE SUPERINTENDENT OF THE COUNTY SOMERSET ASYLUM.

It is stated, on the authority of Pinel, that the greatest number of recoveries from madness take place in the first month of its duration.¹

My experience for several years in the St. Marylebone Infirmary is in accordance with this statement. It arose in this way. The Hanwell Asylum being full, a proposal was made by the guardians of the poor to the Visitors of Hanwell to exchange chronic for recent cases, to which the Visitors refused to accede. In relation to this matter, the following is from the Report of the Metropolitan Commissioner in Lunacy, page 879:—

“In the Lunatic wards of the Marylebone workhouse there were admitted in the years 1842 and 1843, 190 paupers considered as insane. The overseers being able to obtain admission into the Hanwell Asylum for only 27 of these 190 cases, they therefore ceased to apply for more admissions, and left a note at the asylum, requesting to be informed when any vacancy might occur. The overseers also requested permission of the committee of the Hanwell visiting justices to permit some of their old incurable patients at that asylum to be exchanged for recent curable cases from the Marylebone workhouse. This the Justices refused to do, on the ground that the diet was better at Hanwell than at the workhouse, and that the patients enjoyed more comfort at the County Asylum.

“In reference, then, to the populous parish of St. Marylebone, the magistrates of the Hanwell Asylum refused to exchange old incurable for recent and curable cases. But the professed and indeed main object of a county asylum is, or ought to be, the cure of insanity. The patient who has had the benefit of a trial in the asylum where he has become incurable, should, we submit, give way to the afflicted pauper who is in the workhouse or at home, and is probably curable, and equally entitled to be received at the asylum, where by prompt and proper treatment he might be restored to health and to his family, instead of being permitted to become an incurable lunatic, a source of expense to others, and of suffering to himself. A county asylum is erected for the benefit of the whole county, and is to be considered not merely a place of seclusion or safe custody, but a public hos-

pital for cure. A large number of the patients now at Hanwell derive no substantial advantage from the means of exercise and employment furnished in that asylum, and might be provided for in a separate establishment, thus making room for patients who are susceptible of cure.”

Thus the justices of the Middlesex Asylum cause a disastrous result, adverse to the interests of the insane, and, indeed, to the intention of that asylum; and, moreover, needlessly increase the expenses of the county. In short, the greater part of the recent cases are excluded in favour of the vast number that admit of no benefit from treatment, and, in fact, are merely hopeless incurables only requiring safe custody.

“We have called attention to the state of the County Middlesex with respect to its pauper lunatics, because, although the evils which exist there prevail to a very great extent in other counties, they have risen in the County Middlesex with a rapidity which has not been equalled elsewhere, and to a magnitude which appears to us to require the serious attention of the Legislature.

“The disease of lunacy, it should be observed, is essentially different in its character from other maladies. In a certain proportion of cases the patient neither recovers nor dies, but remains an incurable lunatic, requiring little medical skill in respect to his mental disease, and frequently living many years. A patient in this state requires a place of refuge, but his disease being beyond the reach of medical skill, it is quite evident that he should be removed from asylums instituted for the cure of insanity, in order to make room for others whose cases have not yet become hopeless. If some plan of this sort be not adopted, the asylums admitting paupers will necessarily continue full of incurable patients, and those whose cases still admit of cure will be unable to obtain admission until they become incurable, and the skill and labour of the physician will thus be wasted upon improper objects. The great expense of a lunatic hospital is unnecessary for incurable patients; the medical staff, the number of attendants, the minute classification, and the other requisites of a hospital for the cure of disease, are not required to the same extent. An establishment, therefore, upon a much less expensive scale would be sufficient.”

The noble chairman of the Commissioners in Lunacy and Mr. Proctor, also Dr. Prichard, the highest British authority on insanity, signed this report.

In my report as to lunatics chargeable to the parish of St. Marylebone in 1844, which was published after the usual annual visits to the County Asylum and licensed houses, where there were patients chargeable to the parish, it is stated that “there were in the Hanwell Asylum 79 cases, 35 males and 44 females, belonging to the parish of St. Marylebone. The whole of the males were incurable, with one exception, and that one doubtful; 3 of the females were considered curable, 3 doubtful; the remainder incurable; of these, 22 were so quiet and harmless that they might have been advantageously exchanged for recent cases as they occurred in the parish. Although this subject was brought before the guardians in 1841, and again in 1842, when the application was made to the Visitors of the asylum to sanction the exchange, nothing was done to remedy this growing evil. There was not a case in Hanwell of less than a year's duration, after which, according to statistics, a continuance of the disease may be expected. There were about 40 cases in licensed houses and in the infirmary, many of them of recent date. Relapses of convalescent patients, by the introduction of recent cases into the same ward, were of frequent occurrence in the parochial infirmary, the result of defective means of separation. This objection is not confined to the infirmary, for in the workhouse the want of separation of the epileptics, idiots, and imbeciles from the other paupers is equally manifest, and nearly led to suicide in an imbecile, who assigned as a cause the constant jeering of others in the workhouse yard. In the first half-year of 1844 the number of recent cases in the infirmary was about 20, and 31 patients had been sent to licensed houses. The cases admitted were mostly in the prime of life, often with families, and generally engaged in some active business or trade, the temporary depression of which had occasioned a sudden attack of the mental disease. It will be quite obvious that such comprise the most curable of all cases. This indicates another urgent reason why the best acknowledged means of recovery should be made available; for the issue of each case not only concerns its own social relation (a subject of serious reflection), but affects also, very materially, the economy of the parish funds. Convinced as I am

¹ Prichard's Treatise on Insanity, p. 129. London, 1835.

of the impossibility of the insane poor in this extensive parish ever having the advantage of proper treatment in the early and curable stage of their disorder until an asylum is provided for them, I earnestly entreat your Board to take the matter under your serious consideration."

A country establishment for 200 patients was recommended, and the retirement of the parish from further contributions to the Hanwell Asylum, to which it had already been taxed to the amount of about one-eighth of the whole cost of that institution, which it was then proposed to enlarge. It was found that without an Act of Parliament the separation could not be effected, and the matter was ultimately abandoned.

The statistics of the St. Marylebone Infirmary were published in THE LANCET, December, 1841, and in June, 1842, including upwards of 13,000 cases, and in the *Edinburgh Medical Journal*, No. 156, and several subsequent numbers. The infirmary was then a recognised medical hospital, having a staff of physicians and surgeons from the time of Dr. Hooper, and including Drs. Hope, Lee, Sims, Clendinning, Macreight, and Mayo, the President of the College of Physicians, also Dr. Harrison, a distinguished pupil of Laennec, who gave demonstrations in the wards on the use of the stethoscope. Post-mortem examinations were frequent. Dr. Sims was interested in cerebral diseases, Dr. Clendinning in the weights of the organs, and Dr. Mayo was an authority on mental diseases, and Dr. Chas. J. B. Williams, Professor Gulliver, Mr. Kiernan, and Mr. Hutchinson were also actively prosecuting their well-known pathological researches in the infirmary.

After the passing of the Lunacy Acts in 1845 a licence was obtained for ninety-five patients in wards prepared for their reception, with the approval of the Commissioners in Lunacy, in the workhouse and infirmary, where the recent cases of insanity were successfully treated for several years, the great obstacle to the present treatment, the delay in obtaining certificates, being thus avoided. From the necessary delay and the stringency insisted upon in filling up these obnoxious and unnecessary certificates I have known suicide to occur, the discharge of a patient being ordered owing to an informality in filling up the certificate not having been corrected within the allotted time; and I have known of a homicide from delay in obtaining an order of admission, and saw the patient rational after some years in Broadmoor Asylum, where he was retained until his death.

The certificate of the parish doctor, the entry in the registers of admissions at the asylum, and the signature of the chairman of committee of visiting justices to the registers after seeing the patients, would practically fulfil all that is necessary, without subjecting the unfortunate patient to the cruel delay, in many cases to be strapped down in bed by force, and left with broken ribs, whilst the relieving officer is traversing the country for miles to find a magistrate to have an order signed to take the patient to the asylum under the jurisdiction of the magistrates.

(To be concluded.)

AN EXAMPLE OF THE VALUE OF LISTER'S METHOD IN A PHTHISICAL PATIENT.

By GEORGE THIN, M.D.,

AND

J. KNOWSLEY THORNTON, M.B., C.M.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

MR. M—, wine merchant, aged twenty-six, consulted Dr. Thin on Nov. 5th, 1879, under the impression that his health was being undermined by syphilis. He had been under treatment for this disease during six months, and taking without intermission small doses of grey powder. There were no symptoms of syphilis, but he had had gonorrhoea, followed by copaiba rash. He was a feeble, sickly-looking man, with a peculiar waxy pallor, and was of a phthisical family. He complained of increasing debility, of cough, and of a fixed pain, situated over the fifth rib. Physical examination showed tenderness on pressure and pleuritic friction round the tender spot. He was also subject to attacks of asthma, which had troubled him for years. Towards the end of the month a slight boggy swelling appeared over the tender rib. A blister was applied, but gave only temporary

relief. The swelling increased, and by Dec. 7th fluctuation was distinct, when Dr. Thin asked Mr. Knowsley Thornton to see the case in consultation. Mr. Thornton made a small incision antiseptically and evacuated a few drachms of thick curdy pus, a probe was passed into the opening and a considerable surface of the rib was found to be bare and rough; the probe passed along the lower border of the rib for nearly two inches, and for this distance the whole face of the rib was denuded of periosteum. A small drainage-tube was inserted, the wound was dressed with gauze, and the discharge at the first dressing, on the second day after the incision, was considerable; after that it became entirely serous. The dressings were changed on the second, sixth, tenth, fourteenth, eighteenth, and twenty-third days after the incision; then once a week till Feb. 23rd, when the drainage-tube was extruded and the wound healed and Mr. Thornton ceased to attend.

Two weeks after the dressings were discontinued the patient complained for a few days of some discomfort—"a drawing like a boil"—in the old place, but it passed off of itself. During this satisfactory progress and termination of the surgical complication, the general condition of the patient had become steadily worse; night sweats and cough were troublesome; and the physical signs indicated advance of tubercular mischief in the right apex. He was much troubled with pains in the bones; sometimes in the ribs, sometimes in the hips, and once in one of the femora. These pains were localised to a spot tender on pressure, but no swelling was ever detected. A painful point generally lasted some days, and sometimes for more than a week.

In April Dr. Thin strongly advised a voyage to Sydney, and the patient arrived there fat and in good health; the bone pains no longer troublesome. Dr. MacLaurin of Sydney, writing on August 2nd, reported that there was "no trace of the necrosis of the rib, and that the affection of the lung was quiescent."

The following are special points of interest in the case:—First, the effect of a prolonged course of small doses of mercury on an already feeble and phthisical subject. Partial necrosis of one rib, and recurrent periosteal pains continuing for many weeks after the use of the drug had been abandoned and a tonic treatment adopted. Second, the complete restoration of the affected rib without exfoliation. This affords a beautiful illustration of the power of nature to repair, if only protection be afforded against fresh irritation. The diseased bone was kept free from all irritation, escape being provided for the discharges preceding and accompanying repair, and perfect asepticity being secured by the use of Lister's method. Had the abscess been opened without antiseptic precautions, prolonged fetid suppuration and exfoliation must have resulted. The immediate risk to the pleura during the early irritative stages of putrefaction would have been considerable, and had these been successfully passed the prolonged suppuration would probably have hastened the tubercle to such an extent as to render his condition too hopeless for the voyage which has proved of such signal benefit to him.

GREAT NORTHERN HOSPITAL.

INWARD COMPOUND DISLOCATION AT THE ANKLE-JOINT,
WITH FRACTURE.

(Under the care of Mr. GAY.)

For the following notes we are indebted to Mr. Wharry, house-surgeon.

The patient, a young man, aged twenty-one, fell from a scaffolding thirty-five feet high, in a skeleton building, and alighted, as far as it was possible for him to control his fall, on his feet. The results were, first, a comminuted fracture of the left leg about the middle, and, secondly, a compound

inward dislocation at the right ankle, with oblique fracture of the tibia. The joint was very much deformed. The sole of the foot presented itself inwards, as though the whole foot had made almost a quarter of a revolution on its long axis, and there was a large protuberance in place of the malleolus, with a hollow below. On the outer side there was a wound in the integument, through which the external lower end of the fibula protruded to the extent of more than two inches. The bone was denuded of periosteum, but was entire. The lateral ligaments were all torn through, and portions of the peronei muscles were exposed through the rent made by the fibula in the skin. This opening was barely large enough to allow the passage of the bone, so that the edge of the skin was puckered and tucked in behind and below in such a manner that the bone could not be retracted without some help. It is not often easy to study the displacement in these cases, but in this case, after the reduction of the fibula, it was not difficult to do so. The treatment in relation to the fibula was the first point to be considered, and Mr. Gay remarked that where reduction of a protruded bone can be obtained by *enlarging the wound*, he thought it was much better to do so than remove a portion of the bone, unless the question relates to a portion of bone, or bones, as the astragalus, that has been so separated from its connexion as to leave no hope of its retaining or regaining vitality. Mr. Gay made a vertical incision through the skin edge, below the point of the malleolus; but though the bone was easily passed through this opening, it met with resistance at that in the deep fascia. This had therefore to be enlarged in the same direction and to the same extent as that in the integument, when the bone was easily replaced. The nature and extent of the remaining injury could now be ascertained. The end of the tibia had sustained an oblique fracture, which had separated the internal malleolus and almost the whole of its articular surface; and the foot had made partial rotation on its long axis, so that the head of the astragalus was lying partially on its outer side, and had been carried inwards, driving the detached portion of the tibia with the malleolus before it. Mr. Gay could not discover that the astragalus had parted company with the calcis. It was, indeed, apparently Potts' fracture reversed. The reduction, *with the knee-joint flexed*, was easy, and the foot and leg were subsequently placed on a back iron splint with a foot support, and fixed by bandaging. A good dose of opium was given, with the effect of producing sound and salutary sleep. A series of abscesses (three) formed below the periosteum along the spine of the tibia, with a temperature of 105°. These were opened with the effect of a reduction of temperature, and are now discharging healthy pus. In all respects the patient is going on well, with the prospect of having a useful limb, if even the joint should ultimately be stiff.

FISTULA.

Mr. Gay lately operated on two cases of fistula. One in a boy ten years old—a blind track that originally led from the perineal side of the left buttock to a chronic abscess in or adjoining the gluteus, which had almost closed up. It had remained stationary for six years, and still discharged slightly. The opening that remained was found to be of very little depth. Mr. Gay laid it freely open.

Another case was that of a woman aged forty-five, who a month before was seized with symptoms of ischio-rectal abscess. It formed quickly, discharged a large quantity of unhealthy pus, and resulted in fistulous passages, one of which led up behind the sphincter into the rectum, and another—a considerable sinuous passage—which led from it towards the median perineal line, but which turned out to be a cul-de-sac. Mr. Gay cut through the sphincter as usual, remarking that the only unfortunate result to be apprehended in these cases is the occasional permanent loss of power over the sphincter, for which a reason might perhaps be given.

Fortunately it is not often that patients submit to an operation for rectal fistula until some time has elapsed; they find the part does not heal; and this perhaps supplies a reason why the consequence alluded to is comparatively unfrequent. Mr. Gay therefore objects to *early* operations in these cases, and to the use of any other instrument than the knife or sharp scissors; and thinks that, as a rule, they ought not to be resorted to until the walls of the abscess, and as well as of the consequent fistulous track, have assumed a condition of health and a *disposition* to take on a healing process. Unless such a disposition exists in

these parts, the division of the sphincter should not be attempted. It is clear, on reflection, that the *conditions* which *forbid* the healing of such a fistula do not include an *indisposition* on the part of the tissues in which it lies to healthy and reparative activity. These relate simply to the form, it might be, of the sore (the special fistulous track-surface), to the patient's general health, or it may be to the deterrent influences of sphincter activity. At all events, these do not extend to and include the action of the tissues in which the sore is situated. These must be in a sanitary state, and disposed to heal on being released from the operation of those conditions which interpose to prevent their healing, or an operation might be useless. The fistula should be dry, and not unctuous with purulent discharge. Hence Mr. Gay, in these cases, recommends operation being deferred, as a rule, until the sac of the abscess had filled in, and nothing is left but the mere sinuous passage. Operations done before this stage has been reached are those most likely to be followed with fecal incontinence, and this is readily explained by the amount of reparative action that, in the great majority of cases, is required before the parts are in a condition to resume healthy action, embracing a period which is partly occupied by tissue degradation and destruction, preliminary to that of repair, and perchance in part by processes which do not favour that kind of ultimate reunion of the divided textures, including the sphincters, which can alone ensure the restoration of their natural functions.

UNIVERSITY COLLEGE HOSPITAL.

AMPUTATION OF BOTH UPPER LIMBS; RECOVERY.

(Under the care of Mr. GODLEE.)

FOR the notes of the following cases we are indebted to Mr. Stanley Boyd, surgical registrar.

At about 10 P.M., or a little earlier, on the night of June 30th, the patient was crossing a railway line near Willesden Junction; he heard an engine approaching, and suddenly felt fixed to the spot. He became unconscious, and remained so for a time. When he recovered his senses he stated that he got up, and wanted to pick up his coat, which he had been carrying on his arm. He then discovered that he was unable to do so on account of the loss of both his arms. He walked about 250 yards towards the station, then met some friends, who put him in a cab and took him the rest of the way. Tourniquets were at once applied, and he was conveyed to hospital by the next train. At the time of the accident patient was perfectly sober. He was never subject to fits.

At about 11.50 P.M. he walked into the casualty room, assisted by two men. Both arms had been amputated through the upper part of the lower third, the left rather higher than the right. A long narrow strip of skin, which would apparently have reached to the wrist, hung from the left stump. The patient was much excited, but shock not at all marked.

At about 2 A.M. July 1st Mr. Godlee performed a modified circular amputation on each side, saving all skin which seemed likely to live. The bones were sawn near the meeting of upper and middle thirds. On the left side the incision passed through bruised triceps, and the skin seemed a little tight. The patient was a very muscular man. Drainage-tubes were introduced at the outer angles of the wounds, and antiseptic dressings were applied.

He slept well on the first night; ate fish on the second day. On the third full diet was allowed. On the sixth everything was satisfactory, but no firm union had occurred between flaps.

On the evening of the 7th the temperature rose to 100.4° sleep was disturbed, and epistaxis occurred on the following morning, when the temperature was 101°. Circumscribed erythematous patches were found about both knees and other parts.

On the 10th the rash had almost gone, and the temperature had again become normal. Three stitches were removed from the left and one from the right stump, and on the thirteenth day all the stitches were removed, and boracic dressings were substituted for the antiseptic gauze on the left side, the wound being almost healed. Two days

later the same was done for the right, and on the twenty-first day the man was discharged with only a single granulating point about one-eighth of an inch across on right side.

Remarks by Mr. GODLEE.—The case presents two or three points of some interest. It is difficult to understand, in the first place, how it is possible for a train to pass over the arms at the junction of the middle and lower thirds, without causing some injury to the head. In the second place it is worth noticing that with careful antiseptic management, the incision of an amputation may be carried much nearer to the seat of injury than would be at all safe if putrefaction were anticipated. On the left side, for example, the triceps at the point of section was black from extravasated blood, yet the stump healed without the appearance of the slightest blush or the discharge of a drop of pus. Lastly, it offers an interesting problem to the instrument-makers to supply a suitable pair of arms to be of any material service to a strong young man nineteen years of age. It is proposed that he should have a hook on one side, and on the other an arm with an elbow-joint which works stiffly, so that he can shift its position in such a way as to enable him to carry light parcels of varying shapes.

RUPTURE OF CENTRAL PORTION OF EXTENSOR TENDON OF RIGHT THIGH, JUST ABOVE PATELLA, THE LATERAL EXPANSIONS FROM THE VASTI MUSCLES BEING INTACT AND THE KNEE-JOINT UNOPENED.

(Under the care of Mr. Beck.)

The patient, a man of sixty, was going downstairs, lighting his pipe, and had reached the last step, when he fell forwards on both knees on to the landing. As he did so he heard a loud snap, felt no pain, but found that he could not rise on account of something wrong with his right leg. Being set upon his legs he walked to the hospital, keeping the right knee extended and getting off pavements sideways with the right leg first.

When seen he was lying with the right knee fully extended. A slight depression was visible above the patella, causing it to appear unduly prominent. A finger could be pressed on to the condyles of the femur at the depressed point; above the depression was the firm end of the transversely torn tendon; below it, and about one inch distant from the tendon, was the upper edge of the patella. No distinct portion of tendon could be felt on this; but, on the other hand, no scale of bone seemed to have been detached from it. The lateral boundaries of the depression above the patella were formed by the expansions from the vasti to the patella. These were rendered very evident when the patient endeavoured to raise the limb from the bed, keeping the knee extended—an action which he was quite unable to perform. The outer expansion then became a sharp fibrous band—the inner was softer and less prominent. The lower end of the tendon scarcely moved at all in the efforts at extension.

When the knee was flexed over the edge of the bed and the leg hung vertically the patient was able to extend the knee very slightly. He could prevent passive side to side movement of the patella by the vasti muscles.

There was not the least swelling of the knee-joint, no effusion between tendon and patella, no bruising of skin, and no pain or tenderness.

The limb was placed on a back splint, and both it and the body were well raised on inclined planes. There was never any effusion into the knee. Gradually the lower end of the tendon became a little swollen and rounded off, and a firm material filled up the gap to a certain extent, so that the finger could no longer be pressed on to the femur. There remained one-half to three-quarters of an inch separation between the tendon and the patella.

On the twenty-ninth day the patient was discharged, wearing a plaster-of-Paris splint from groin to ankle, and walking with crutches.

The plaster soon rubbed the skin over the patella, and was replaced by a simple back splint.

On the fifty-sixth day this was removed. The depression above the patella was very slight, and its boundaries, given above, were still distinct. The lower end of the rectus tendon was rounded and thickened. The interval between it and the patella was about three-quarters of an inch; apparently there were no adhesions in the knee.

ALNWICK INFIRMARY.

EXTENSIVE LACERATION OF BOTH FOREARMS WITH FRACTURE OF THE BONES; RECOVERY.

(Under the care of Dr. MAIN.)

For the following notes we are indebted to Mr. F. A. McEwen, M.B., resident medical officer.

G. T—, aged six years, was admitted into the infirmary on July 9th, 1880, suffering from extensive laceration of the soft parts of both forearms, with fracture of the bones. On the day before admission he had been in the hayfield, where his father (a farm labourer) was driving a hay-reaper. He had, unseen by his parent, got close behind the knife-board while the machine was in motion, and for some reason had reached over his left hand in front of the knives, and was caught by the middle of the forearm. Before the horses could be pulled up he tried with his right hand to extricate the left, with the result that it also was caught in the same way and frightfully mangled.

On examination it was found that the left forearm was diagonally cut right through in the fleshy part of the upper third, both bones being divided and the forearm all but severed. A rude splint had been bandaged along the outer aspect of the forearm, and the wound had been stitched. The right forearm presented the following appearance:—A large portion of the muscular tissue on the anterior aspect had been torn away in a mass, the ulna was fractured, and the thumb had been amputated besides a part of one finger.

The injured limbs were placed on pillows and the wounds were dressed with carbolic oil (1-20). In two days the stitches in the large wound on the right forearm had to be taken out and the wound gaped considerably.

For the first ten days after admission the pulse stood at 136, and the temperature varied from 99° to 100·2°. There was slight sloughing of the large wound on the right forearm, after which it granulated healthily, and twenty days after the accident that arm could be moved about. On August 15th the left forearm was put up in a starch bandage, the bones having united, and the wound having cicatrised to a considerable extent. The forearm was a little bent on its anterior aspect, and the hand could not be pronated and supinated. Patient was discharged on August 21st, with the promise of two useful arms.

Remarks.—The case was first seen on the spot by Dr. Main, along with the local practitioner who was called in at the time of the accident. It was thought then that double amputation was the only chance of saving the boy's life, though there was naturally an anxious desire to try to save one limb. There was a difficulty in deciding which limb had the better chance, and as the boy's surroundings at home were not at all conducive to success he was admitted into the infirmary. The result was most gratifying.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Osteitis Deformans—Rickets.

THE ordinary meeting of the Pathological Society was held on Tuesday, Dec. 7th, the President, J. Hutchinson, Esq., in the chair. Mr. Treves showed an interesting living specimen of osteitis deformans, and other specimens and cases bearing on the subject of rickets were exhibited. The Debate on Rickets was resumed by Dr. Dickinson, and was chiefly remarkable for a vigorous speech from Sir William Jenner, after which it was again adjourned.

Mr. TREVES brought forward a living specimen of Osteitis Deformans, the subject being a woman, aged forty-eight, whose mother had been crippled with "rheumatism" for six years before her death; with this exception her family had been very healthy and long-lived, and she herself had enjoyed robust health, and had not suffered from rickets or any serious disease. She was the mother of twelve children, the last was born when she was thirty-four years old, was very rickety, and died at two years and two months, four others

died in infancy, and two children, born when she was respectively twenty-eight and thirty-five, showed slight signs of rickets. Five years ago she had aching pains in her legs after standing and walking, quite absent at night; a year later she noticed that the left shin was growing out. She is now so weak that she cannot walk more than half a mile; the left tibia is much bent forwards and slightly out, quite smooth, and not tender; the right tibia less affected. The right femur is bent forwards and out, the left femur is unaltered in shape. There is no œdema. Both ulnæ are prominent, and the right is distinctly bent back. She stoops a little with a bend in the upper dorsal region of the spine, and her friends have noticed that she has grown shorter of late. There are no other bony changes.

The debate on Rickets was then resumed.

Dr. DICKINSON.—I will venture, Sir, in obedience to a request with which you honoured me, to say a few words upon the state of the viscera in Rickets. The enlargement of some of the abdominal organs which occurs with rickets was not very prominently referred to by Dr. Fagge, but I understood him to express an opinion in opening the discussion (I judge by the report of his speech, which I had not the advantage of hearing) that this visceral enlargement was rather an accidental accompaniment of rickets, brought on by similar causes, than properly a part of the disease. I do not hold this opinion, but regard the swelling of the organs just as much a part of rickets as the change in the bones, and believe the two to be closely analogous. This enlargement has attracted the attention of many observers, old and new. Whistler thought that "the obstruction" in the liver and spleen was the first departure from health. We, perhaps, know the condition best from the description of Sir William Jenner in his well-known lectures. I will briefly sketch an outline of the changes as they have come under my own observation. It belongs to the rickety period of childhood; I have notes which show it between the ages of seven months and four years, I daresay the range is actually wider. The spleen, liver, and lymphatic glands become enlarged; the spleen most so, the lymphatic glands least; of these the mesenteric glands show the most decided swelling, the superficial glands, perhaps, becoming shotty to the touch, but without more decided tumefaction. The enlargement of the spleen may be such that the organ fills half the belly, reaching from the ribs to the pelvis, and from the lateral aspect to the median line. All degrees of enlargement up to this are to be found, the lesser being the more common. The liver does not undergo the extreme enlargement which the spleen does, though it is common to find it projecting two or three inches below the ribs. The increase in the viscera is a form of hypertrophy which bears resemblance to that which occurs in the bones. There is no new growth or deposit, only an irregular development of the proper tissues of the organs. The interstitial substance is largely increased, and the epithelial and corpuscular elements somewhat. The portal cellular tissue of the liver is soft, loose, and visibly and measurably magnified, and displayed on the cut surface by a pattern of minute hexagons, one round each lobule. In the spleen the trabecular tissue is similarly increased, so that its threads, which should be in as slender proportion as those of a net, are sometimes as wide as the spaces they enclose. The swollen organs are not materially altered in shape or in smoothness of surface. The Malpighian bodies of the spleen do not undergo the same transformation characteristic of the lardaceous condition, nor do any of the affected structures give the iodine reaction. The rickety enlargement is totally different in all respects from the lardaceous. The earthy salts would seem to be diminished in the viscera as in the bones. I examined a well marked rickety spleen, and found the earthy salts in a given weight reduced by two-thirds as compared with a healthy spleen examined at the same time. I think there can be no reasonable doubt that the swelling of the viscera is as much a part of the rickety condition, and as essentially belongs to it, as that of the bones. It is, however, to be remarked that when the visceral change is most marked that in the bone is seldom extreme, as if its disease exhausted its force in one direction or the other. It is amenable to treatment, though slowly. Under cod-liver oil, iron, and hygienic measures a spleen which touched the pelvis may gather itself up so as to be nearly out of reach of the fingers. The symptoms of this form of organic enlargement are less marked than those of the lardaceous; jaundice and ascites are not known among its results, though when the spleen is greatly affected there may be marked anæmia.

Dr. GEE wished to dwell on one point, apparently a small one, but which he believed to be of great importance. When seeing the out-patients at the Children's Hospital he came to the conclusion that it was very uncommon for rickets to commence after the first year of life, but he was aware that some, as Trousseau, spoke of rickets as sometimes occurring in adult life, and he should be glad to have that question finally answered. Mollities ossium has been spoken of as a rickety change. He had no experience of the disease, but it was so uncommon that it hardly invalidated his view that rickets is really a disease commencing in the first year of life. He had been much struck with M. Parrot's statement—stronger in his printed paper than in his speech—that syphilis is not only a cause, but the cause of rickets. Amongst other objections to this view is the fact that rickets is met with in animals; he was familiar with it in dogs, where, as in the human species, it occurred in the young only. It was, of course, competent for M. Parrot to reply that this was a different disease, but the *onus probandi* of that would rest with him and his followers.

The PRESIDENT, in reference to the subject of mollities ossium that had been raised, handed round the photograph of a skeleton in the Brighton Museum, which he had received from Dr. Ormerod, which displayed the changes in mollities ossium in a very marked degree. The subject had two fractures during birth, and was believed to be rickety in infancy, but grew out of it, and was well till thirty, when mollities ossium developed, and before fifty, the time of death, every bone had become bent, and innumerable fractures had occurred. The subject had had two daughters, who were rickety, one of whom died after the operation of Cæsarean section performed on account of a typically rickety pelvis. He thought this case illustrated some connexion between mollities ossium and rickets.

Dr. NORMAN MOORE first referred to a point in the history of rickets suggested by a reference of Dr. Fagge to Whistler as the discover of rickets; this claim rests only on the assertion of Whistler that he printed a thesis on it in 1645, but there is no trace of this thesis, and in face of the fact that Whistler appropriated to his own use some of the funds of the College of Physicians, his own unsupported statement was of small value. Glisson is known to have been at work on rickets in 1645, and he published his work on it in 1650, a book which marked the dawn of medicine after the darkness of the middle ages. One development of rickets Dr. Moore thought had been overlooked, this was a heaping up of bone at the edge of the vertebral centra, which he had observed in the majority of cases. It is sometimes considerable when the beads on the ribs are small, and it leaves a permanent deformity, which is liable to be confounded with the results of rheumatoid disease. He had calcined in a platinum crucible equal portions of two rickety ribs, and of two healthy ribs, all from children under two years of age, and found the quantity of earthy residue as near as possible the same, so that he was inclined to believe that the quantity of earthy salts in rickety bones was but slightly, if at all, diminished. On May 2nd he examined minutely a child aged five, in whom whooping-cough was commencing; her chest was of normal shape, and she had no symptom of rickets; the cough was severe. On August 13th she had a distinct pigeon breast, and the case answered Dr. Fagge's question as to the necessary association of rickets with this deformity of the chest.

Mr. WARRINGTON HAWARD.—In dissertations and discussions upon rickets it has been usual to lay great stress upon the bone changes which accompany the disease, and this is very natural and proper when it is considered how large a part they play in the disease and in the production of its most obvious symptoms. Dr. H. Fagge, however, pointed out at the onset of his remarks that rickets was a general disease, of which the bone lesions are but a part. I would go further, and say that the bone changes are not always a prominent part of rickets, and that he who looks only for these signs of the disease will fail to recognise some of the most severe cases. It may be useful, therefore, to recall attention to the condition of some of the other organs, especially the muscles and ligaments. Rickets may be described as a special form of debility, the stress of which falls upon the organs of motion—the muscles, ligaments, and bones. A special form of debility because it has concomitants which distinguish it from all others, and make rickets a very definite disease. I allude, of course, to the marked tendency to certain convulsive affections, which is so great as always to bring rickets to our minds if we see

a child who has no marked fever attacked by fits or laryngismus; to the singular sweating about the head and upper part of the body; to the extreme tenderness, and often to the great fatness, of the children, which last symptoms make it less easy to detect what would otherwise be more often noticed—the enlargement of the viscera, and the slight enlargement of the lymphatic glands. With these symptoms are seen certain changes in the apparatus of motion, among which is a notable weakness of the muscles and ligaments. If a child who has walked becomes rickety one of the earliest symptoms is an unsteadiness of gait, soon followed by an inability to walk. The mother says, "The child is taken off its feet." This inability to walk is not because of the changes in the bone, which are probably coincident, but because of the muscular weakness, which shows itself in other ways—e.g., the bowed spine of rickets depends upon the weakness of the spinal muscles, which are not strong enough to keep the spine erect. So the prominent abdomen depends not only upon the visceral enlargements, but on the weakness of the abdominal muscles, which yield to the weight of the viscera they cover. The knock-knee and flatfoot are other instances of muscular weakness; the muscles being weak, undue stress is thrown upon the ligaments, which, being soft, readily yield. But the cases in which the muscular weakness is most marked are those of acute rickets in very young children. A case was related in illustration of this. A child, ten months old, rapidly and almost completely lost the power of moving its extremities. The lower limbs were everted and motionless, the upper limbs occasionally moved in a slow and languid manner. The child was enormously fat. The fontanelle was widely opened and depressed, it sweated profusely about the head and upper part of the body; it was intensely tender, so that it screamed if only gently touched. The spleen was palpable. The upper incisor teeth only were cut. The father was very healthy, the mother fragile, and had had children fast. This was the fourth child, the three others being healthy. Neither of the parents had been rickety. It had been brought up by hand and fed partly on Swiss milk and partly on a patent farinaceous food. Here the muscular weakness was so great as at first sight to simulate infantile paralysis, and the bone lesions were very slightly marked; but a careful examination revealed nodulated ribs and slight enlargement of wrists. It would be interesting to know the microscopical changes of the muscles in such cases of acute rickets. In less severe cases the only changes I have found are that the muscular tissue is pale and ill developed. With regard to the bone changes: doubtless a marked symptom of rickets is the widely open fontanelle and its long delayed ossification. But if we exclude the retarded ossification, I should say the changes of the cranium are usually more of shape than of tissue. The head is flattened at the top, and bulges at the front and sides. But we do not find the remarkable prominences around the fontanelle often associated with cranio-tabes, and which Drs. Lee and Barlow have shown to be often accompanied by marked symptoms of syphilis. Dr. Fagge objected to the observations of Drs. Lees and Barlow that they have been too ready to exclude rickets in their cases because of the absence of beading of the ribs, and that they did not weigh with sufficient minuteness the condition of the epiphyseal line by section of the bones. But it must be remembered that Drs. Barlow and Lees did not merely exclude rickets, but they found syphilis; it was not merely that they found rickets absent, but they found syphilis present in the majority of their cases, and they interpreted the meaning of the cranio-tabes by its concomitants, and gave strong reasons for regarding it as a symptom of syphilis rather than of rickets. So with the long bones. The enlargement of the long bones seen in some cases of inherited syphilis is of a quite different nature to that of rickets, and leads to separation of the epiphyses (of which specimens were shown, to contrast with the ricket changes), and the loss of power in the limbs in these cases is due to inflammation and not to muscular weakness, as in rickets; and the bone changes are associated with a quite different train of symptoms in the two diseases,—so that the cases of rickets and syphilis are quite distinct and separable.

Mr. PARKER considered that one of the most important points to decide was the age at which rickets first begins, and thought a good deal of the pathology depended on this. Was rickets congenital? English authors in the past had, for the most part, answered this question in the negative; but German authors, including Bednár of the Vienna

Foundling Hospital, Dr. Ritter, and Dr. Vogel, had recorded well-marked instances of congenital rickets. Then, if congenital, was rickets hereditary? It seemed difficult any longer to disregard hereditary influence, when one remembered what a large proportion of London children were rickety, and what an influence must be exercised by such parents on their offspring, especially when born under social conditions favourable to the further development of such constitutional peculiarity. Sir William Jenner had drawn especial attention to the influence which unfavourable hygienic causes acting on the mother must exercise on the fetus *in utero*. By congenital rickets he did not mean *fœtal* rickets. He had not seen rickets as ordinarily understood in children under one month, but that was due, perhaps, to the fact that in younger children the rickety manifestation escaped the mother's notice altogether, and never needed medical treatment. He agreed with Dr. Elsässer that cranio-tabes was a sign of rickets, and was found quite independently of syphilis. He could not, therefore, agree with Dr. Lees and Dr. Barlow in the view they had expressed that syphilis was the largest factor in the disease. Neither could he accept M. Parrot's doctrine, that rickets was a late stage of syphilis. He thought it might with greater truth be argued that the rickety lesion in bones predisposed to the syphilitic, in the same way that a blow not unfrequently seemed to develop the tubercular diathesis in a subject in whom it had previously been latent, or even unsuspected. There were points of contact between mollities ossium and rickets which rendered it impossible to ignore them, and he was pleased that the President had introduced that subject into the debate.

Sir WILLIAM JENNER.—Sir, I published three lectures on rickets in 1860, and I have nothing to add to or take away from them this evening, and I can therefore have no objection to any reference being made to those lectures in this debate; indeed, I wish there had been fuller reference to them. Contrary to the views of Dr. Fagge and Dr. Eustace Smith, I see no reason to regard rickets as other than a diathesis. Dr. Smith quotes a passage from Dr. Aitken as a definition of diathesis, and then shows how rickets differs from this definition, but I cannot allow that the question is thereby settled. By a diathesis I mean a certain disposition to disease. The child of an ill-nourished mother is disposed to become rickety when placed under unfavourable circumstances after birth, or even under favourable circumstances in some cases. I do not see how that differs from tuberculosis or scrofulosis—for I still recognise a difference between these—or congenital syphilis. A father acquires syphilis and begets a child with congenital syphilis, a mother gets weak and bears a rickety child; or the parents are tubercular, and their children if in unfavourable circumstances develop tubercle. I know that a word is nothing, but still I think we want a word to group these conditions all together. In reference to pigeon-breast, I would say that it very often arises from other diseases than rickets, but the two varieties are very easily distinguished. In rickets the deformity is due to the softening of the bones which yield at their growing ends and push forward the sternum as a rounded prominence, and the outline of the chest is a double curve. In pigeon-breast from non-rickets causes the yielding of the ribs takes place where there is a natural maximum bend, at their angles, the sternum is pushed straight forward, and the outline of the chest is angular. The tenderness of muscles has been referred to to-night; that is an old observation, and in my lectures I spoke of the tenderness being as great in the abdomen as in the thigh; I could not say more. At that time I examined the muscles in many non-acute cases, but did not find any special and distinct changes. The weakness of the muscles was one argument used years ago against Rokitsansky's view of the mode of production of pigeon-breast. Dr. Fagge has referred to the excretion of excess of uric acid as a possible cause of rickets; in my experience this is a very common condition in children whose health is disturbed, and I imagine it has little bearing on the disease. With reference to the question of syphilis, which is very important, I may observe that twenty years ago I pointed out one strong argument which I believe still holds good. If a person is syphilitic the first child often escapes from the continuance of the influence of the antisyphilitic remedies in the parent, but it is the early children who suffer from syphilis. In rickets, on the contrary, it is the latter ones that suffer, and among the poor, if one child has rickets, all the later ones are rickety. In the upper classes

this is not such an absolute rule, as the mother often ceases to bear children for a time, leaves home, and re-establishes her health before another pregnancy. Another strong argument is, that all of us know persons, whose word we can trust implicitly, who are incapable of deceiving us, who assure us that they never had syphilis, and yet they have rickety children. I could quote several such cases, and, for my part, I hold that syphilis and rickets are quite distinct. Dr. Gee's argument in this matter is very strong, but it is open to M. Parrot to assert that rickets in animals differs from the disease in man. With reference to the cranium, I think it has been stated that the bones of the skull are not much affected. On the contrary, I have found that they are often very seriously affected in rickets, and the change is found in front, often there is quite a depression over the suture between the two frontal eminences, the condition being identical with that in the ends of the long bones. Many rickety children are exceedingly fat, and I do not regard emaciation as due merely to rickets, but to the changes in the internal organs, especially in the lymphatic glands. Similar changes in these glands lead to emaciation in older children. I cannot think that what Dr. Dickinson has stated to-night about the changes in the internal organs explains what one sees. I have seen the liver like glue, and the spleen, when cut into thin slices, transparent, and these appearances cannot be explained by hypertrophy of the cells and fibrous structures of these organs. We see great development of fibrous tissue in cirrhosis of the liver, but the appearances to the naked eye and common lens are totally different from those of the rickety liver. True, it does not absorb iodine, nor does it show the characteristics of the amyloid or lardaceous degeneration of these viscera. I have seen a large number of spleens after ague and various Indian fevers, and the cut surface has not appeared to me identical with the structure of the rickety liver. With regard to the shape of the head, it has been stated by one speaker that if you flatten down the head from the top you get the head of rickets: my observation tells me that while the hydrocephalic head is increased in both its antero-posterior and transverse diameters, the rickety skull is long and narrow, and the forehead is unduly prominent in proportion to the breadth of the head; this is due to the development of much albuminoid substance in the white matter of the anterior lobes of the brain. As to the chemical characters of rickety bones I am no authority, and we have not heard much to-night from others on this part of the question; one speaker has examined two bones—that is not much. But there are two or three points which ought to be referred to; one is the statement of Lehmann, that on boiling rickety bones they do not yield ordinary gelatine, but an animal matter resembling that of malignant bony growths; he observed also an enormous quantity of lime excreted in the urine, even as much as six times the normal amount; such statements are well worthy confirmation or refutation. Is the yielding in cranio-tabes the result of the pressure of the brain or of the pillow? I always thought it was the pillow. I have seen rickets begin in children seven and eight years old.

Dr. BARLOW exhibited a tabetic cranium from a child who died of meningitis, at the age of seven months, the mother was a healthy woman with abundance of good milk, there were no signs of rickets whatever, and the fifth and sixth ribs—those specially liable to beading—were shown, there was no proliferation of the epiphyseal line, and they were quite healthy; if rickets were going to develop it would surely have shown itself by seven months. There was a pretty conclusive evidence of syphilis, and the cranium showed the development of a layer of very fine bony deposit following sinuous lines, as described by M. Parrot. Cranio-tabes is rarely seen earlier than three months, and by that time the early evidences of syphilis—the rash and catarrh—have disappeared, but a child was shown with marked cranio-tabes, who still exhibited a syphilitic rash over the body. In new-born children the bones of the skull are very firm and compact, and the tabetic condition is certainly an acquired one. No doubt many tabetic children become rickety, but his assertion was that very many of them have signs of congenital syphilis at some period; syphilitic children are, perhaps, specially exposed to the influences which produce rickets. There are three factors in the production of cranio-tabes—first, marked softening of the bone; second, weakness in the child; third, the pressure of the brain and the pillow on the softened bone.

Dr. TURNER exhibited anatomical and microscopical specimens of rickety bones.

Dr. DREWITT showed microscopical specimens of rickety bones.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

The Clinical Features of Pleural Effusions.

At the meeting on the 6th instant, F. J. Gant, Esq., President, in the chair—

Dr. DOWSE brought forward two patients suffering from nervous disease, in both of whom the eye symptoms were the most marked of the objective signs. *Case 1.*—A man, aged forty-nine, suffering from locomotor ataxy, who had been in good health with the exception of fulgurant pains up to two years ago. Defective vision and right ptosis came on in July, 1879. There was double optic atrophy, and the other signs of tabes were marked; and there was altered sensation in regions supplied by the fifth nerve. *Case 2.*—A man, aged forty-five, the subject of intra-cranial tumour. Four years ago he first complained of occipital headache and vomiting; there was optic neuritis with commencing atrophy.

Dr. BROADBENT then read a paper upon "Some Points in the Clinical History of Effusion into the Pleural Cavity." He first enumerated and explained the relative importance of the physical signs of pleural effusion, and pointed out that the curved line of dulness was due to the manner in which the lung shrinks around its root, and as the fluid rises the vocal resonance and vibration become exaggerated over that part of the chest-wall where the lung is still in contact. When the cavity is full of fluid the respiratory murmur may be conducted for a short distance across the back from the unaffected lung. Sometimes, however, the lung was prevented from collapsing by adhesions, by consolidation, or congestion; and he believed the persistence of bronchial breathing in such cases was due to imperfect collapse of lung, although the fluid was in large amount. The chief point he wished to urge was that while the ordinary signs of effusion into the pleural cavity—dulness, extinction of vocal fremitus, diminution of vocal resonance, and limitation of bronchial breathing to the region of the root of the lung—show that the lung retreats and shrinks before the fluid, loud tubular breath sounds at the base of the lung posteriorly and over the lateral and anterior aspect of the chest show that the lung has not entirely retreated, but that it retains a certain volume, and is more or less deeply immersed in the fluid. The patency of the bronchi and the partial condensation of the lung favour the transmission of sonorous vibrations. It is in these circumstances that egophony is heard most distinctly and widely—from the thin layer of fluid intercepting some vibrations and transmitting others—conditions which ordinarily exist only in the earlier stages of effusion. In some of these cases there may occur some degree of vocal vibration at a period when the amount of fluid is sufficient to give dulness on percussion over the entire lung. Paracentesis would be of comparatively little value in such conditions, for the quantity of fluid is small, and the consolidation of the lung would persist after its removal; and most cases of this sort get well without resort to paracentesis. In one such case only 30 oz. of fluid could be withdrawn. The conditions are met with in the pleural effusion of renal disease, often accompanied by congestion, and partial consolidation of the lung preventing its collapse; also, in effusions which rapidly became purulent, as in empyema in children. Apart from these cases, the signs indicative of a large congested lung deeply immersed in the fluid are prognostic of rapid absorption, and Dr. Broadbent had seen this now in a sufficient number of instances to enable him to predict with considerable confidence the recovery of the patient without paracentesis and in a comparatively short time. One of the first steps towards recovery is a rather sudden disappearance of the tubular breathing and the substitution of the more ordinary signs of simple effusion; and it is probable that the congested lung has relieved itself by diffusion of serum into the pleural cavity, and that the amount of fluid there is actually increased. In conclusion, Dr. Broadbent stated the rules which guide him in recommending paracentesis. It should be resorted to at once when there is serious con-

tinued or paroxysmal dyspnoea; but in the absence of urgent symptoms a week or ten days may be given after one side of the chest is full, on the chance that absorption may set in, and a longer period still when the lung has not greatly shrunk. Old age, phthisis, or a phthisical tendency, are reasons for early tapping, as also is the existence of disease of the kidneys. The spot for puncture is the eighth space, in a line with the angle of the scapula, and he had come to prefer the common trocar and cannula, with antiseptic precautions to the aspirator. The whole of the fluid should never be removed, or attempted to be. Where the effusion has lasted some time frequent partial emptyings are to be preferred.—Dr. C. T. WILLIAMS referred to a case of pleural effusion with presence of marked bronchial breathing and vocal vibration, and alluded to the valuable aid in diagnosis rendered by the use of a hypodermic syringe.—Dr. DE HAVILLAND HALL mentioned a case of sarcomatous growth filling the pleural sac and collapse of lung, yet with presence of vocal fremitus. In one case he had withdrawn 107 ounces of fluid, and he asked the author as to the amount he would recommend to be withdrawn.—Dr. MUIR asked for information as to other modes of treatment.—Dr. HABERSHON spoke of the various forms of pleural effusion—e.g., in renal and in cardiac disease, secondary to pneumonia or due to primary pleuritis. He recalled a case of Dr. Addison's where a small area of bronchial breathing existed, surrounded by complete dulness and absent breath-sounds. The autopsy revealed a portion of lung adherent to the chest-wall at that spot. He pointed out that many cases recover if left alone. If there were high temperature, hectic fever, and tendency to tubercular disease, and if dyspnoea were present, he would advise paracentesis, especially if empyema were suspected.—Dr. HARE said the physical signs were often misleading, especially in children; the presence of vocal fremitus and respiratory murmur on the affected side was only to be accounted for by conduction from the healthy side, through the compressed lung and fluid.—Dr. WHARRY asked how far vocal fremitus and tubular breathing were indications of the existence of uncollapsed lung in the fluid. He had seen at least one such case where these signs were absent. What were the author's reasons for assuming that exudation took place from the lung into the pleura in certain cases.—Dr. GILBERT SMITH agreed with Dr. Hare as to the difficulty of diagnosis in children. He instanced a case where the lung was wholly collapsed, notwithstanding presence of fremitus and tubular breathing, and asked whether a purulent effusion did not conduct vibrations better than a serous one. He also asked whether the disappearance of these signs would not be better explained by an increase in the effusion and pressure on the lung than by an exudation from the lung itself.—Dr. BROADBENT, in reply, said he had not seen cases of vocal vibration and bronchial breathing with collapsed lung, nor could he explain such. The persistence of vesicular breathing implied the existence of a non-collapsed lung. He did not consider that increase of pressure explained the disappearance of bronchial breathing, for almost invariably improvement quickly followed—ushered in by returning apical resonance. He had not practised injections into the chest in serous effusions, but had frequently and with benefit employed solutions of iodine in cases of empyema. He now preferred to use the simple trocar inserted near the angle of the scapula; this allowed of the withdrawal of the right amount of fluid, while the entrance of air did no harm. If the aspirator were used it was his practice to stop as soon as the patient became distressed or attacked with cough. Eighty-four ounces was the largest amount he had ever drawn off.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

Serous Cysts—Cases of Neuralgia dependent upon Non-erupted Teeth.

ON Wednesday, November 17th, 1880, A. W. N. CATTLIN, Esq., President, in the chair, brought forward a case of two separate Serous Cysts, complicated with an alveolar abscess, all in different parts of the superior maxillary bone, and each unconnected with the antrum. The palate on the right side was enlarged, and the first right upper molar and the right and left upper lateral incisors had been removed.

Over this latter spot were two small openings in the alveolar process through which flowed a clear serous fluid. Prior to the patient's leaving England Sir James Paget was consulted, who considered the case to be one of extremely rare cystic disease, and recommended the immediate extraction of the lateral teeth and further treatment deferred until his return from abroad. The President remarked he did not ever remember having seen a case in which the discharge from the cyst passed by a pulsating movement in jerks as it did on both sides in this particular instance.

Mr. AUGUSTUS WINTERBOTTOM then read a paper "On Cases of Neuralgia dependent upon Non-erupted Teeth," and stated that the diagnosis of the true seat of nerve pain is sometimes attended with extreme difficulty, and often (notwithstanding our utmost endeavours) its real cause remains buried in obscurity. The author then narrated three cases as bearing upon the subject:—Case 1 was that of a young woman, aged twenty-one, suffering from neuralgic paroxysms affecting the left side of the face. On examination a second bicuspid was found carious, which was extracted. The patient was not again seen for a year, when she returned and stated that she had suffered continuously more or less since the operation. A small fistulous opening was discovered in the position lately occupied by the bicuspid, and on probing there was a sinus about one inch and a quarter in depth, with a substance closely resembling dead bone at the bottom. The sequestrum, however, did not appear movable, but an offensive fluid could be pressed out from the antrum. Its solution was attempted, unsuccessfully, by means of sulphuric acid, and at length an operation was imperative. Under ether, Mr. Winterbottom introduced into the sinus a long, narrow-bladed pair of forceps, and succeeded in grasping a small roughened semi-detached fragment, which, on withdrawal, was found to be the partially developed germ of the second premolar tooth. The wound healed rapidly, and the pain did not return. Case 2 was that of a lady, age forty, with persistent neuralgia affecting the left upper jaw. The left upper central incisor, being loose, was extracted and the pain subsided. The patient returned in about eighteen months, having been free from suffering in the interim, but annoyed by a continual discharge proceeding from a small fistulous orifice over where the tooth had been taken out. On probing a piece of apparently carious bone could be detected, seemingly immovable. On dislodgment with strong stump forceps it was found to be a carious upper canine tooth; and the patient recovered her health.—Case 3 was one of greater severity, and demonstrates the fact that removal of the first cause does not always permanently cure the disease. D. B., aged forty, was admitted into St. George's Hospital suffering from intermittent facial neuralgia; and medical treatment failing, he was referred to the author prior to resorting to nerve-stretching. The disease had been active for twelve years, and the patient had to throw up his employment. On examining the mouth nothing abnormal presented itself, the gums being healthy, with the exception of a small fistulous orifice (which required a magnifying mirror to discover), no larger than a pin's-head, over the position of the right central incisor. On pressure a little glairy fluid could be squeezed out; and the sinus, some half an inch long, on probing a smooth round body could be felt. Mr. Winterbottom divided the tissues down to the bone, and excised a small portion of the alveolar process, and grasped what on examination proved to be a partly disorganised canine tooth, lying with its long axis parallel to the lower margin of the jaw. At the end of three weeks he was discharged cured, and for nine months remained free from pain, when his former symptoms recommenced. About a year from the date of his previous admission he re-entered St. George's Hospital, when Mr. Pollock removed a piece of bone from the superior maxilla, comprising that portion corresponding to the interval between the left central and canine teeth inclusive, leaving a chasm in the mouth some one and a half inches long and half an inch wide, with its deeper portion opening up the floor of the nares and interior of the antrum. The excised mass revealed nothing abnormal, and the man's condition was in no way improved. At this stage he again saw the patient and endeavoured to ascertain whether another buried tooth existed, but no resisting material was met with. The next step consisted in an operation for nerve-stretching, performed by Mr. Pollock, who cut down upon the second division of the fifth in the position of its emergence from the upper jaw, and, seizing the main trunk, applied considerable traction. This treat-

ment availed nothing, and the patient returned home in a worse plight than when he set out; Mr. Winterbottom had since been unable to gather any further particulars. In conclusion, the author remarked that often an exciting cause may be overlooked, and its removal, as in Case 3, be insufficient to establish a cure; that, as a rule, he could not too strongly insist upon the necessity of eradicating the source of mischief at the earliest opportunity; that often great difficulty is experienced in determining whether diseased bone or a carious tooth lies at the bottom of the sinus, and that it is sometimes advisable to cut down upon foreign bodies and attempt their extraction, even if not movable. The deductions to be drawn from these cases are, that careful microscopical examination should always be made of the mouth and gums, and that the presence of diseased bone alone does not usually produce persistent neuralgia; that when we find in the mouth a sinus leading down to exposed roughened material (coincident with continually-recurring neuralgic paroxysms), our suspicion should be aroused, and that it is our duty to cut down upon and investigate the true state of affairs.—The PRESIDENT, on behalf of the Fellows, thanked Mr. Winterbottom for his instructive paper, and stated that in these cases he always used and preferred trephines (of various sizes) to cutting forceps. A discussion ensued, in which Mr. Hamilton Cartwright, Mr. Edgelow, Mr. E. Bartlett, Mr. Keene, &c., took part.

Reviews and Notices of Books.

Croonian Lectures on some Points in the Pathology and Treatment of Typhoid Fever. By WILLIAM CAYLEY, M.D., F.R.C.P. London: J. & A. Churchill. 1880.

THOSE who attended these lectures when they were delivered will be glad of the opportunity given for a perusal of the many suggestive facts and reasonings which they comprise. Dr. Cayley has constituted himself the champion of the cold-bath treatment of typhoid fever. He is almost the first among modern English physicians to advocate this treatment in the thorough and systematic manner in which it is carried out by Brand of Stettin and many others abroad; and the whole drift of his argument tends in this one direction: that by the use of antipyretic measures (of which none is more reliable or certain in its action than the cold bath), a very palpable effect is produced in lessening the mortality from typhoid fever. The distinction which he draws between the primary fever following upon the taking in of the poison and the secondary fever due to the processes of intestinal ulceration and sloughing is one of the main arguments in favour of the early adoption of these measures, and he claims to show that the good effects of such treatment are better marked, and success more certain, when the febrile process is controlled almost from the beginning. So far as statistics go, and with due allowance for fallacies, it would certainly seem that the adoption of such measures has lowered the rate of mortality; but in order to get the best results it is necessary that every case should be submitted to the treatment, for no one can predict at its onset whether a case of typhoid fever will be severe or not. It seems hard to accept this, knowing that from past experience at least 80 per cent. of the cases of typhoid fever will recover under careful nursing, diet, and "expectant" treatment; but if it be true that at least a further 10 per cent., if not more, will be rescued from death, there should be no shrinking from the employment of a method, however irksome in its application, that leads to such a result. As to the dangers of the treatment itself, these seem to be comparatively few. Chronic pulmonary and cardiac diseases contra-indicate the method; so also does intestinal hæmorrhage—not, Dr. Cayley thinks, because the application of cold causes increased vascular turgescence of the abdominal organs, but because of the absolute

necessity for complete repose to favour the arrest of the hæmorrhage.

The lectures, however, are not limited to this one subject of treatment, although that forms the main topic to which the others lead up, but they detail valuable facts in the etiology and pathology of the disease, and place the whole subject in so clear a light that they will have a permanent value for reasons other than those involving the advocacy of a particular line of treatment.

General Paralysis of the Insane. By WM. JULIUS MICKLE, M.D., M.R.C.P. London: H. K. Lewis. 1880.

THE elucidation of the true nature of the morbid conditions resulting in "general paralysis of the insane" has long been attempted by writers on mental pathology. The subject is one of the most difficult in medicine; the views propounded have been most varied; the lesions described most numerous. To collate all that has been written on the subject, and to combine therewith the fruits of his own experience, has been the effort of the author of this book. As a solid contribution to the subject, the book is one of considerable value; but it is far too heavily laden with doctrines which have long been abandoned to be serviceable; and the author's style is not attractive in itself. It testifies to a profound acquaintance with the literature of the subject, and will be mainly valued as a work of reference. Nothing seems to have escaped his observation, and in the chapters on symptomatology, etiology, diagnosis, and morbid anatomy, the facts that he has accumulated are detailed with a degree of care that is at once commendable and painful. The book, however, is not intended for the student; and the very features which would render it unsuitable for him will make it more acceptable to the mental physician.

Space will only permit us to state briefly the views to which the writer has been led upon the pathology of this disease. It is primarily (in the majority of cases at least) an affection of the cerebral cortex, the meninges being more or less involved at the same time. In many cases the morbid change is partial at first, in others it is more widely diffused, and the parietal and frontal regions chiefly suffer. The change affects the nerve-cells; it underlies their functional derangement and exhaustion; and in so far as it involves those elements which are most concerned in mental operations, and those which have to do with motor and sensory functions, so in proportion do mental, motor, or sensory derangement follow. This, in brief, is the sum and substance of a long argument filling several pages. No doubt there is a definite and special lesion underlying the phenomena of general paralysis, but these phenomena are so varied and complicated, involving, too, the most as well as the least complex of the cerebral functions, that a satisfactory pathological interpretation is a matter surrounded by the greatest difficulty. It would be desirable, doubtless, to introduce a system of classification and nomenclature whereby the different forms of this disease could be more clearly differentiated. This may be possible some day; and the data contributed by Dr. Mickle will be found of service to whomsoever undertakes the task; and when this is done for general paralysis a great step in advance, as regards the pathology of insanity in general, will be made, for in its manifestations this complex disease reproduces the characters of many of the forms of insanity. Dr. Mickle pushes the theory of cerebral localisation to its extreme limits, applying it to account for mental disorder as for motor; and in so doing he has given an impetus to inquiry [which may result in great gain to knowledge.

The volume concludes with full notes of several cases illustrative of the various forms of the disorder.

Conspectus of Organic Materia Medica and Pharmacal Botany. By L. E. SAYRE, Ph.G. Detroit: George S. Davis. 1880.

THE present time is scarcely opportune for the appearance of a work, intended for medical students, which deals only with the botanical and pharmaceutical relations of organic drugs. It is not, indeed, too late. Botany and commercial pharmacy still constitute subjects on which the student has to exhibit a knowledge in his professional examinations, and to which, therefore, he has to devote a portion of his too scanty time, acquiring at infinite pains an acquaintance with botanical facts and with commercial characteristics of raw samples, which, as Dr. Michael Foster said in his address at Cambridge, "might admirably qualify him for a situation as buyer to a wholesale drug-house." But signs are to be discerned that a change is not far distant. On all sides is heard a protest against useless knowledge acquired at pains which are only equalled by the ease with which the knowledge is lost. Into the mind of the student of average capacity there can only be packed, in a limited time, a limited number of facts, and the unessential knowledge displaces that which is important. The changing conditions of practice are fast removing all practical reason for retaining, among the subjects of compulsory study, the facts which constitute the subject of the work before us. When the motive of practical utility is gone, the retention of these subjects cannot be justified on the ground of the mental training which they afford. This is equally and better furnished by other subjects, which cannot be dispensed with. It is true that these objections to such a treatise are of less weight in the country in which it is published than here. The business of the chemist and the doctor is less widely separated in America than in England, at least if we are to judge by the appearance of a journal which we lately noticed, which is intended to be a common organ for druggists and physicians. In this country a treatise on such a limited subject may be useful to the student of pharmacy, but scarcely to the student of medicine.

A "conspectus" is always a more or less uninteresting work, suitable for reference rather than for perusal. This quality may reasonably be expected to be specially marked in a work which deals only with the driest of dry subjects. Such an expectation is not falsified by the work before us. Written throughout in a terse and condensed style, while even abbreviations are employed to economise space, it comprehends only an outline of the bare facts of botany and the chemistry of drugs. It commences with a chart of the materia medica which is obtained from the organic world. Here, in successive columns, are described the natural order, officinal name, botanical name, common name, habitat, part used, constituents, medical properties, dose, and officinal preparations of each drug. The seventh of these columns includes the only facts of direct medical interest contained in the work. We have next a table of the geographical grouping of the organic materia medica. The facts given in this table are probably entirely useless for practical, and even for examinational, purposes; for we trust that no examiner is yet, or will be, so cruel as to expect a candidate in medicine or pharmacy to enumerate all the drugs which come from the shores of the Mediterranean or from Central America. The next chapter is occupied by a brief outline of structural botany, too condensed to be of service, by an explanation of various botanical terms, and by an outline of the various natural orders. The rest, and chief part, of the volume is occupied by an account of the characteristics, constituents, adulterations, &c., of the various drugs of organic origin. These are arranged, not according to the natural orders from which they are derived, or according to their action, but according

to the part of the plant from which they are obtained. Thus we have successive descriptions of those which are obtained from roots, rhizomes, tubers, bulbs, stems, wood barks, leaves, herbs, flowers, &c. Hence jalap and aconite, turmeric and ginger, mustard and Calabar bean, lemon-peel and pomegranate bark, colocynth and capsicum, are severally described in juxtaposition, and opium is classed with india-rubber and gutta-percha. On the other hand, forty pages intervene between the descriptions of the leaves and root of aconite. It is evident that a work on such a plan can be useful to druggists only, and not very useful to them. A conception of the character of the information given may be gained from an extract. We take, at random, that of *Pilocarpus*, which is described under the section "Leaves," subsection "Nearly sessile, lance oblong, retuse, base unequal."

"*Pilocarpus pinnatifolius*—Jaborandi leaves are nearly sessile, pinnate with a terminal leaflet, general outline ovate. The leaflets, which are from two to five in number, joined at the axis by short petioles, are uneven at the base, about two inches in length, lance-oblong in outline, apex marginate or retuse, veins quite prominent, always parallel near the margin, and unite near the apex, covered with oil-cell; coriaceous, aromatic. *Pilocarpia*, an alkaloid, and a vol. oil are its constituents."

But although the general scope and style of the work render it scarcely suitable for medical students, the design is executed with care and precision. The descriptions of plants and of drugs and their adulterations, although not fuller than is to be found in most standard text-books of materia medica, are accurate as far as they go. The work is well printed, and we can only regret that so much care and pains have been bestowed on a work which must be of limited utility.

OUR LIBRARY TABLE.

Ringworm: its Diagnosis and Treatment. By ALDER SMITH, M.B. (Lond.), F.R.C.S., Resident Medical Officer, Christ's Hospital. London: H. K. Lewis. 1880.—This little book, which is a reprint with many additions of the excellent observations contributed by Mr. Smith some little time back to the columns of THE LANCET, deserves to meet with wide acceptance at the hands of those members of the profession who from time to time have to treat cases of ringworm. It does not profess to be an elaborate treatise on vegetable parasitic diseases, but it is a short, thoroughly practical, and sound exposition of the diagnosis and treatment of the several kinds of common ringworm, with especial reference to ringworm of the head (*Tinea tonsurans*). On this subject Mr. Alder Smith is peculiarly able to speak from his large experience amongst the candidates for admission to Christ's Hospital, and such experience has taught him, and in this all who have had much to do with ringworm must agree, that a very great number of medical men, from one cause and another, fail to make themselves thoroughly acquainted with the method of growth of the fungus and its consequences, and so do not appreciate sufficiently the desirability of an early treatment and the extreme difficulty in curing chronic cases, and that they are, more or less, in the dark as to when a case is really cured. It surely ought to be the duty of every medical man to be thoroughly acquainted with an affection so common amongst young children of all classes, and so apparently trivial, yet so productive of worry and annoyance, and we can cordially recommend the guidance offered by Mr. Smith. A special feature of the work is the advocacy of an undoubtedly effective plan of treatment for *very small inveterate patches of chronic ringworm*. This consists in the artificial production of kerion, chiefly by means of the careful application of croton oil, a remedy much favoured in France, but rather

for the production of pustules around the hair-follicles than real kerion. The class of cases in which this treatment is desirable, and explicit directions for carrying it out, are described with great clearness and care. A further useful plan for eradicating the diseased hairs in "disseminated ringworm" is suggested—viz., the thrusting of a gold needle dipped in the croton oil into the follicle itself. The concluding chapter on Ringworm in Schools, including the questions of "certificates" and "isolation," ought to be of great value, coming from one in Mr. Smith's position. In any future edition we should be glad to see discussed the management of that not uncommon and troublesome class of cases in which ringworm flourishes over a head attacked by eczema or seborrhœa.

Clinica Oftalmologica del Dr. PEDRO F. ROBERTS. pp. 282. Buenos Ayres: Coni. 1880.—Dr. Roberts's clinic is conducted for the present in the Hospital de Mujeres, and in the course of the year 1879, 582 new patients were under treatment, with 25,550 attendances and 102 operations. The number of the affections of the orbit and lacrymal apparatus treated amounted to 31; of the eyelids to 74; of the conjunctiva 273, of which no less than 83 were cases of trachoma; of the cornea 211; of the iris 21; of the sclerotic, choroid, and vitreous humour 16; of the optic nerve and retina 11; of the lens, including cataract, 15; of strabismus 9; of the whole eye 6; of amblyopia from alcohol 2; ciliary neuralgia 1; and of errors of refraction 15. Besides these Dr. Roberts gives the numbers seen in his own private clinic, the total of which was 411, with 64 operations. Dr. Roberts states that he has made much use of jaborandi as a means of producing sweating in acute iritis, in some cases employing its active agent, pilocarpin. The dose in which this was employed was ten drops of a solution containing forty centigrammes of pilocarpin chlorhydrate dissolved in twenty grammes of water. In the course of three minutes the patient begins to experience a sensation of heat in the skin; the forehead then becomes moist, and sweating soon becomes general, with abundant discharge of saliva. It sometimes produced a sensation of tenesmus, and a painful feeling in the perineum. He finds scrofula a very common affection in Buenos Ayres, as elsewhere. His cases of cataract he treats with the linear incision and iridectomy, and he seems to have obtained fairly good results. He has practised with success the operation of canthoplasty in several cases of granular lids. A considerable portion of the book is occupied with a series of lectures, giving a general account of ophthalmic diseases and their relation to medicine. We hope that next year Dr. Roberts will find both his public and private clinic increased in numbers, and that we will be able to give an equally good account of his cases.

Elements of Astronomy. By ROB. S. BALL, LL.D., F.R.S. pp. 459. Longmans. 1880.—The editing of the Text-books of Science of Messrs. Macmillan has been committed to very good hands, as the "Electricity and Magnetism" of Professor Jenkins, the "Theory of Heat" by J. C. Maxwell, and the "Structural and Physiological Botany" by Thorne, amongst others, testify. The first chapter of the work is devoted to a consideration of the instruments employed in astronomy, without going more deeply into their construction than any ordinary reader can easily follow. The earth is then briefly described, with the diurnal motion of the heavens, and the means at the disposal of the astronomer for determining it. The several luminaries are successively described, as the sun, moon, planets, comets and meteors, stars and nebulae. The last chapter treats of "Astronomical Constants." Many of the facts mentioned are very interesting. Amongst others, the following may be mentioned:—The heat from the moon has been found to be equal to one-third of a candle

placed at a distance of 4.75 metres, and by Lord Rosse to be the same as if its surface were at a temperature of 360° F. = 182° C. The mean distance of the earth from the sun, as concluded from the observations of the transit of Venus made by the astronomers sent out in 1874 by the British Government, is 93,300,000. From this the diameter of the sun may be calculated to be 860,000 miles, or about 110 times the diameter, or 1,330,000 times the volume, of the earth. The spectroscopic characters of the sun's rays are discussed. The work is illustrated by a large number of diagrams and sketches. Those of the spots on the sun are particularly well executed.

The Mouth and the Teeth. By J. W. WHITE, M.D., D.D.S.—This little work is one of a series of health primers edited by Dr. Keen of Philadelphia. The author deals with the subject of which he treats in a simple and popular style. His book cannot, as we assume it does not pretend to be, a scientific work upon diseases of the mouth and teeth, and consequently we are disinclined to criticise its pages. But as it has been brought prominently before us, we feel compelled to caution the student against trusting to such an imperfect treatise as a guide to practice. The book, however, contains some good advice as to the care and preservation of the teeth in childhood and adult life. Had the author confined his attention almost exclusively to the subject matter of the seventh and eleventh chapters of his book (the former treating "Of the Care of the Temporary Teeth," and the latter "Of the Food in its Relation to the Teeth") and regarded his remarks as being addressed to nursing women, we might probably have been able to write in approval of his labours.

Cottage Hospitals. By H. C. BURDETT. Second Edition. London: J. & A. Churchill. 1880.—The benevolent founders of village hospitals are very often entirely ignorant of the principles upon which such institutions should be constructed and managed. Mr. Burdett's book contains a mass of information, statistical, financial, architectural, and hygienic, which has already proved of great practical utility to those interested in cottage hospitals, and we can confidently recommend this second edition to all who are in search of the kind of information which it contains. The chapter which touches upon hospital mortality is, we believe, entirely misleading, and we could wish it had been omitted, for so difficult a subject is manifestly beyond the province of one who is not a member of the medical profession. Chapter 15, which gives plans and details of some of the best cottage hospitals, is perhaps the most useful in the book, and should be carefully studied.

London Smoke and Fog. By FREDERICK EDWARDS, jun. London: Longmans. 1880.—This little pamphlet about the "burning question" of the hour is written in a lively style, and the author criticises, not without justice, many of the grates and stoves which have of late been introduced to public attention. The grate which the author recommends is provided with a brick bottom, perforated, not solid. He further provides a valve in the chimney, which can be worked by a handle over the mantelpiece, to regulate the draught. There is further an arrangement, similar to that in Galton's grate, for admitting heated fresh air into the room.

A STRANGE OUTRAGE.—The following paragraph appeared in *The Echo* of the 8th inst. A gentleman, named Rosslyn, residing at Reigate, Surrey, having sent a servant who was ill to the hospital to be nursed, incurred the indignation of a number of roughs, some twenty of whom surrounded his house late at night, broke several windows, and did other damage, causing great alarm. The men left in a noisy and riotous manner, threatening to repeat the outrage. The affair has created considerable indignation.

THE LANCET.

LONDON: SATURDAY, DECEMBER 11, 1880.

In the *Gazette* of the 3rd inst. a Royal Warrant was published, establishing rules for the future promotion, relative rank, and allowances of the officers of the Indian Medical Service. These have now been assimilated to those in force in the Army Medical Department, and thus one of the just causes of complaint to which we recently called attention (*THE LANCET*, October 2nd) has been removed. Among the benefits conferred by the Warrant is the institution of the grade of Brigade Surgeon; and to remove any feeling of injustice arising from the delay which has occurred in the promulgation of this measure, it is ordered "that the promotions to the rank of Brigade Surgeon, made in the first instance under this our Warrant, shall have effect from the 27th of November, 1879." By this clause the Surgeons-Major, who would have been promoted with those of the Army Medical Department, had the Warrant been extended in the first instance to the Indian Medical Service, will regain the position on the seniority list to which they would then have been entitled. The invidious distinction of keeping the Surgeon-Major of twenty years' service in the position of *junior* Lieutenant-Colonel has been abolished, and he will henceforth take relative rank according to the date of his commission, with the single reservation that he cannot sit as *president* of a court-martial, an exception existing also in the Army Medical Department. The Surgeon is also to have the relative rank of Captain, according to the date of his commission; and a step of honorary rank to medical officers on retirement is sanctioned after twenty years' service instead of after twenty-five, as under the late regulations. All promotions from the rank of Surgeon-Major to that of Brigade Surgeon, from that of Brigade Surgeon to Deputy Surgeon-General, and from the latter to Surgeon-General, "shall be given by selection for ability and merit," and in the case of the two senior grades the grounds of selection are to be stated in writing and recorded in the office of the Secretary of State for India in Council. This definition of the manner in which promotions are to be made appears to us to prevent the possibility of the recurrence of the promotion of a Surgeon-Major to be Surgeon-General, overstepping the intermediate grade, a proceeding which recently gave rise to much, and we are bound to say justifiable, discontent.

The Warrant further introduces into the Indian Service the regulation now in force in the Army Medical Department, of compulsory retirement of Surgeons-Major and Brigade Surgeons at the age of fifty-five, and of Deputy Surgeons-General and Surgeons-General at the age of sixty. But in the case of executive officers who entered the service before January 13th, 1860, and who have not been promoted to the administrative grade before reaching the age of fifty-five, power is given to retain them in the service for three years more on their perfect competency and fitness being

certified to the satisfaction of the Secretary of State for India.

We congratulate the Indian Medical Officers upon the promulgation of this Warrant. There are still some grievances which call for redress, such as the examination of surgeons for promotion, the time spent on sick leave at home not being allowed to count for retirement, and the inadequate rates of retired pay, but these are not of a nature to have been included in the new Warrant. They will require careful consideration on the part of the Indian authorities, and will, we have no doubt, receive due attention from the Marquis of RIPON. The steps already taken by the Government may be accepted as evidence of their intention to act in a liberal spirit towards this important branch of the service, and to remove, as far as in them lies, all just causes of complaint.

THE Warrant regulating the appointment, promotion, and retirement of the medical officers of the Household Troops, which was understood to be ready in May last, but the issue of which was for some reason suspended, has at last been promulgated. It provides, as might have been anticipated, that the medical officers may be borne on the establishment as regimental officers, and that the grades, the relative rank, and the rates of pay, temporary half-pay, and non-effective pay shall be the same as laid down by the Warrant of 1879 for the Army Medical Department. The promotion is to be by seniority in the medical establishment of the brigades of cavalry and infantry respectively, without limit as to length of service, but only on a vacancy occurring in the senior ranks. To meet the case of surgeons who may complete fifteen years' service before such an event occurs a special rate of pay of 17s. 6d. per diem is granted them until promoted. The nomination of medical officers will remain, as at present, in the hands of the colonels of the regiments, but must be made either from the successful candidates at the army competitive examination, from those nominated by the Secretary of State under the provisions of the Warrant of 1879, or from surgeons already serving in the army; all surgeons thus nominated must have passed through the course of instruction at Netley before being gazetted. In the case of officers transferred from the Army Medical Department, the seniority in the brigade for promotion will be reckoned from the date of being gazetted to the regiment. Exchanges with army medical officers are to be permitted, provided that in the case of those above the rank of surgeon the conditions as to foreign service required by the Warrant of 1879 have been complied with. There is nothing special laid down in the Warrant as to brigade surgeons, but in the Secretary of State's instructions it is stated that "the brigade surgeon of the brigade of Guards will be an executive officer, though available for administrative charge." We infer from this that the senior surgeon-major of the Guards will be promoted to be brigade surgeon, and will be considered the head of the Guards' medical officers, and the recognised adviser in all professional matters of the general commanding the brigade. The Warrant appears to have been well considered, and removes in a satisfactory manner those grievances to which we lately called attention (*THE LANCET*, May 22nd and June 12th), while it at the same time affords an opportunity of establishing within the brigade itself an efficient supervision in sanitary matters.

WE are within a month of the meeting of Parliament for the "despatch of business," and it is of great consequence to the medical profession, and still more to the public, to know whether this comprehensive expression is to include the settlement of long-pending questions connected with the efficiency of the medical art. There are many who talk as if Parliament had nothing else to do than to discuss the troubles of Ireland, and to devote an occasional evening to the sins of Turkey and the unfulfilled clauses of the Berlin treaty. People who talk so are guilty of the greatest disparagement of Parliamentary work, which has to do primarily with everything affecting the security of life. Care for the efficiency of the medical profession is one of the prime duties of the State, inasmuch as such efficiency has the most obvious bearings on the mitigation of human suffering and the protection of human life. It has been shown before a Select Committee of the House of Commons that some of the principal examining bodies of the country—in virtue of possessing whose diplomas men practise in all branches of the medical profession—do not examine men at all, or examine them very inadequately, in one or two of the great departments of medical duty. It has also been shown that large numbers of men who commence the study of medicine never succeed in entering the profession, and that many of those who do enter do so only after one or more failures. Much proof has been adduced that this unsatisfactory state of matters is largely due to the inefficiency of the General Medical Council, which has shown itself more tender towards the pecuniary interests of the numerous corporations of which it is principally composed, than to the medical students whose education it was meant to supervise and to improve. These facts have been more or less admitted by two Governments and two Parliaments, and by the Medical Council itself, and they are matters of universal belief in the medical profession.

The question is, What is to be done? Some say, Nothing. The wish is father to the thought. Corporations that notoriously think themselves perfect see no justification for change. Half diplomas have existed from time immemorial. Half diplomas require two Corporations, with two sets of officers and two sets of fees. Why should one examining body do its work thoroughly, when by half doing it excuse can be found for two? What does the medical profession exist for but to keep up its Corporations and to magnify the men who manage the affairs of these ancient bodies, and look after their interests in the General Medical Council? If such arguments prevail with the present Government it will be the first instance in history in which a Government whose boast it is to adapt institutions to the times, and so to preserve them, has refused to effect a reform indicated alike by those who demand it and by those who oppose it. The Government has an opportunity of passing a measure which will really benefit the public and be approved by two-thirds of the medical profession. It is inconceivable that if this fact is clearly brought home to the Government it should hesitate to reappoint the Select Committee and complete the investigation already so far advanced. One thing is certain. The Government must not excuse itself from initiating medical legislation by alleging any serious want of unanimity in the medical profession. Barring the Corporations, or a few of them, whose opposi-

tion is always forthcoming, and, indeed, to be expected, the profession is most harmonious in demanding the abolition of half diplomas, of competition in medical licensing examinations, and the reform of the General Medical Council, by which it shall have more will and more power to initiate and carry out improvements in the medical schools and in the Medical Register. Even the Scotch Universities, which have shown, as we think, unnecessary and unworthy fear of medical legislation, have made proposals which show that they will not finally stand in the way of a great measure of reform if it be brought on earnestly by a strong Government. They have expressed their willingness to have examiners appointed by the Conjoint Board on the Medical Council, associated with their own examiners, or to have it enacted that candidates for their degrees shall not be licensed till they have passed the examination in clinical subjects of the Conjoint or State Boards which it is proposed to appoint. This question touches England much more largely than Scotland, inasmuch as we want 15,000 practitioners in England, and have little help from English universities, whereas in Scotland there are less than 2000, and the majority of Scotch students are educated in the Scottish universities. But the concessions above referred to are enough, with a distinguished representative of the Scotch Universities in the Government, to justify us in concluding that terms can become to with them. Under these circumstances the medical profession will be disappointed, and will blame the Government, if another session passes over without such an amendment of the Medical Act as will abolish for ever half diplomas, and create a Medical Council that the profession and the public can respect.

NURSING is not a craft; still less can it be regarded as a profession. There are specialties in cooking and other departments of domestic work; and there may, therefore, be professed cooks, and waiters, and housemaids, and washerwomen; but there ought to be no specialty in nursing, and there can be nothing professional in the work. The sole qualifications required for tending the sick are kindness, gentleness, and quiet cheerfulness of manner, patience, physical strength, a light and dexterous hand, and the sort of intelligence which renders it easy to take in ideas of work quickly, and to pick up ways of doing what has to be done in a cleanly fashion and decently. For the rest, the nurse ought to be the servant of the doctor, and should carry out his instructions.

If our younger brethren do not themselves know how to direct the making and application of poultices, the snipping and dressing of blisters and bedsores; if they are unacquainted with the details of bandaging, of bathing and changing their patients,—they have not mastered one of the most important branches of their profession. When an engineer commences the study of his business, he works in the pattern-shop and perfects his knowledge of the practical parts of his profession before he essays the higher branches; so that in after-years he not only directs but supervises, and if occasion needed he could with his own hands do what he requires from those who serve under him. We of the medical profession adopt a different course. We begin at the top, and as it is not pleasant working downwards, it too

often happens that the physician who has never been a general practitioner, and the surgeon who has "shirked" as much as possible of his dressing, can *only direct*, and must depend on the assistance of a "professed nurse" for the carrying out of his remedial *intentions*. Instead of knowing, from having himself handled, every rope in the ship, he is a quarter-deck seaman, who can shout scientific orders through a speaking-trumpet, but could not himself execute one of them properly even at a pinch. It may seem rough on our profession to write thus plainly, but it is the truth we are telling, and a little plain speaking now and again can harm no one, and may perchance do some good. The fact is, the practical training of physicians and surgeons, to which we have alluded, lies at the root of the supposed, or rather the assumed, need for "professed nurses."

The "trained nurse"—that is, the woman trained to nursing as a specialty—is an anomaly. Every scrap of information she possesses beyond the mere routine service of sick-tending is not merely useless, but mischievous. It is almost sure to be brought to bear on the patient, to the injury of the case and the disadvantage of the medical attendant. A trained nurse is a half-educated woman, who has acquired just enough knowledge to make her dangerous. The sick person is regaled with reminiscences of other "cases" attended by the trained nurse, *with this or that* physician or surgeon. She is the chief and the prominent figure in the pictures painted for the edification of the patient and the friends. The "doctor" occupies a subordinate place, and is changeful. Sometimes it is one, and sometimes another practitioner, and the nurse does not scruple to state her preference, which is generally for the medical attendant who most defers to her judgment and leaves the patient practically in her hands. She has no scruple in forming an "opinion" of the case, and little, if any, hesitation in expressing it. In reply to the very natural question, "What do you think, nurse?" she delivers her dictum as a skilled authority, and both patient and friends are much impressed by what she has to say on the subject. Not a few of these intruders into the sick chamber employ their own methods, and even administer their own remedies. The sick are wholly at their mercy. They are trusted and obeyed because they are "trained nurses." The medical profession is keeping up and extending this evil by recognising the trained nurse. The policy adopted is opposed alike to the best interests of the sick and of the profession. If practitioners either lack the knowledge or the inclination to give personal and explicit directions for the "nursing" of their cases, they must at least understand that by entrusting the duty to trained nurses they are jeopardising the lives or the health of the patients who confide in them, and sacrificing their proper professional influence.

The remedy for this state of matters is simple, but we fear it will rarely be found easy to carry it into effect. The more independent and *experienced* of practitioners should set their faces against the employment of "nursing helps" and "professed nurses" who lay claim to any special knowledge or *profess* to have studied nursing as a craft. The "sisterhoods" are, in fact, organisations for the propagation of special religious views, and to extend the influence of particular ecclesiastical schools and systems.] The sick chamber

seems to them a "field" or "vineyard" for this work. They cannot so easily get into private families or hospitals as by assuming the *rôle* of nurses, and with them the end justifies the means. We must take it for granted that no self-respecting medical practitioner would aid in this underhanded mission by recommending the employment of a member of any sisterhood except in a family of her own way of thinking. There is no lack of respectable women who are not professional, and who are well qualified and willing to obey implicitly the instructions of the medical attendant. It would be well if the names of such persons were duly recorded in the Visiting List for 1881, so that no embarrassing need for a nurse should compel the practitioner to fall back—as often happens—on the aid of a "professed nurse" in the emergency. Another matter of interest to which we are anxious to call attention is the expediency of employing male attendants for male patients. It is a mistake to suppose that women are necessarily the only good nurses. In the opinion of some persons who claim to be judges of the question, they are neither so quiet, so self-possessed, so precise, nor so strong as men. It is alleged that no man who has been nursed by a gentle-handed male servant would desire, in any subsequent illness, to be attended by a female. It is said that whatever element of the female character or influence is desired in the sick-chamber, can be best contributed by the presence of a mother, a wife, or a sister. When the circumstances exclude these forms of the luxury it can seldom be a necessary. If the employment of men to nurse men were encouraged a great difficulty would be surmounted, and a good social reform begun. The whole subject is one of pressing interest, and the hints we have now thrown out are intended to state the question rather than to discuss it. There is urgent need to uproot growing prejudices, and to amend grave errors and misconceptions to which special circumstances have given rise.

IN a recent epidemic of relapsing fever at Königsberg Dr. LUCHHAU has investigated the frequency of ear and eye complications. Since no less than three hundred cases were treated in the town hospital, the field for observation was unusually favourable. Only one hundred and eighty cases were specially examined as to the existence of ear complications, and these were found in fifteen only, and in all the middle ear was the part affected. In most cases there was suppuration, and the pus was evacuated through the tympanic membrane. In most cases of disease of the middle ear in acute maladies the inflammation appears to arise by extension from the throat; but it was found that, in relapsing fever, pharyngeal catarrh is absent, as a rule, in the cases in which the middle ear suffers, and there was no evidence of disease of the Eustachian tubes. The prognosis is not unfavourable if prompt treatment is adopted.

Only six cases presented eye symptoms out of the hundred and eighty examined (3½ per cent.) In three there was iritis, which was unilateral in every case. All these cases did well. In one case, however, some weeks later the patient complained of failure of sight, and opacities were discovered in the vitreous. In two other cases optic neuritis occurred. In one the affection was discovered in the first relapse. The second relapse was severe, and some time afterwards there was atrophy of the optic nerves, and vision was reduced to $\frac{1}{16}$.

In the other case the neuritis also occurred during the second febrile attack; a few days after it had ceased the swelling of the optic papilla was discovered, dirty-red in colour, with arteries narrowed, and veins distended and somewhat tortuous. Vision was reduced to $\frac{1}{2}$ in one eye and $\frac{1}{3}$ in the other. Another patient came into the hospital during the first relapse with iritis and hypopion. The ocular trouble healed completely, but after the relapse the patient insisted on leaving the hospital, and passed through the second relapse at home, under very unfavourable conditions. When it was over he returned to the hospital with double iridocyclitis. Numerous thick flakes were seen in the vitreous, the fundus was very indistinct, but the papillæ were seen to be red and swollen, and there were numerous retinal hemorrhages. The account of these cases is published in the October number of Virchow's *Archiv*.

THE Registrar-General of Jamaica has somewhat recently issued a report upon the vital statistics of that island for the period from 1st April, 1878 (the date on which civil registration commenced) to 30th September, 1879. This report, which is the first that has been published for Jamaica, is on that account the more interesting. It is, however, to be seriously regretted that the report was not made up to the end of the year, in order that future reports might relate to the natural year; reports for other and irregular periods being to a considerable extent useless for comparative purposes. One of the most interesting features in the report is that which deals with certification of causes of death in the island, and the information which is furnished bearing upon the number and proportion of medical practitioners. It appears that in only 1608 of the 13,011 deaths registered in Jamaica during the year ending September, 1879, was the cause certified by registered medical practitioners; in 9565 cases the cause was supplied by the person registering the death; and in the remaining 1838 cases no satisfactory cause was assigned. This large proportion of uncertified causes of death is in great measure attributed to the difficulties of travelling, which prevent the general attendance of the sick by medical men, but the Registrar-General calls attention to the fact that in some of the chief towns, where skilled aid is at hand, there is also a marked excess of uncertified causes of death. At Morant Bay so many as 304 out of 339, at Port Antonio 89 out of 102, at Annotto Bay 224 out of 242, at Chapelton 232 out of 253, at Lucea 233 out of 269, and at Montego Bay 263 out of 283 were uncertified. Even in Kingston itself 46 per cent. of the deaths registered during the year under notice were "non-medically attended cases"; it is, however, noted with satisfaction that during the seven months ending April last this proportion declined steadily from 40.1 to 18.4 per cent. It is, however, beyond doubt that the medical profession is very inadequately represented in the island, and that a large accession to their numbers must be made before medical aid is brought within the reach of all classes. The report states that there are in Jamaica 66 registered medical practitioners, or one to every eight or nine thousand of the population. In Kingston there is a medical man to each 3000 inhabitants, while in the remainder of the island exclusive of Kingston there is but one medical man to more than 11,000 persons. It may be stated that according to the last issue of the Medical

Register the proportion of medical practitioners in the United Kingdom averaged one to every 1532 persons. More than twenty-five years ago, the scarcity of medical men in Jamaica was the subject of an elaborate report drawn up by the Central Board of Health, the result of which was the establishment of the dispensary system, with provision for the establishment of district medical men. It is now, however, proposed to extend the dispensary system, and the subject of a further supply of medical aid throughout the island is under further serious consideration.

Annotations.

"Ne quid nimis."

THE YORK-ROAD LYING-IN INSTITUTION.

FOR some time this institution has been passing through a severe crisis. We have forbore to discuss the personal questions raised, as we cherished the hope that ultimately the troubles which beset the management might be surmounted. It is now, happily, possible to believe that this desired consummation has been reached. The lately vexed question has been settled, and two good men have been appointed to fill the responsible posts of physicians. Dr. John Williams and Dr. F. W. Champneys have been elected unanimously. We hail the selection of these gentlemen as a promise of good management in the future. They are men of high repute among their brethren, and the interests of the hospital and of the profession are safe in their keeping. We heartily wish them success.

MEDICAL "INDULGENCES."

IT is amusing to notice how, as the season of festivity approaches, the advertising columns of the newspapers, and more particularly of those essentially modern luxuries the illustrated Christmas annuals, teem with testimonials to the efficacy of divers remedies for the effects of excessive indulgence in "the pleasures of the table." It seems as if the main body of the nation—men, women, and children—must needs consume the largest possible quantities of the delicacies of the season, and the art of the drug-compounder is taxed to provide what may be described as "indulgences." It is not the church that grows rich at this Christian festival, but the vendors of curiously devised potions having, or at least claiming to have, virtues available for the cancelling of debts contracted with Nature in the shape of indigestion, gastric disturbances, bilious fevers, and the like, entailed by over-eating and too free drinking. This is a very silly business. Why cannot people be sensible in their enjoyments? If plum-pudding disagrees with them, why, in the name of common-sense, do they eat it? If punch, heavy wines, and spirituous beverages upset the system, how comes it to pass that "the season" is held to excuse the folly of taking these things and daring the consequences? It is too much to expect that any English household will have the moral courage to dine without a plum-pudding on Christmas-day, nor is it to be desired that any should do so, but the conventional dish might at least be made digestible. It is not necessary to stint the proportion of sound fruit in the concoction. The way to render the mass less injurious than it is wont to be to the consumer is to boil it longer and to leave out of the composition some of the more hard and irritating ingredients—for example, the lumps of candied peel that no amount of boiling will soften; and to make and serve it without the ale, spirits, and rich sauces which, however appetising, are not essential, and probably do the worst of the stomach-disturbing and blood-heating.

Then, again, as to beverages, surely there might be a little more than common caution observed in imbibing unaccustomed drinks and regaling children with liquors which do not form part of their ordinary diet, and are essentially exciting. It is a wrong practice to injure the health at Christmas, trusting to the aid of remedies at once nauseous and debilitating for the relief which, it is foreseen, will be surely needed afterwards. It may seem strange to write thus, but there are considerable sections of the community among whom there is a steadily growing demand for these medical indulgences.

SUFFICIENT ASYLUM-ACCOMMODATION FOR LUNATICS.

THE mania—for such it must assuredly be—which impels the justices of counties to persevere in the chase of that will-o'-the-wisp “sufficient asylum-accommodation for lunatics,” is still one of the most noticeable evidences of the alleged “increase of lunacy.” It does not seem to occur to the justices of any one county that it might be worth while to try the experiment of establishing a small hospital in each district, through which all occurring cases should be passed, remaining not longer than six months, before adding these fresh units to the ever-accumulating population of registered lunatics. This plan of procedure has been again and again recommended, and we venture to predict that it would lead to a saving of thirty per cent. in the total expenditure for the maintenance of lunatics in any county where it was properly tried. The essential conditions are that the hospital should not contain more than three hundred beds, that it should be worked as a hospital in every respect, receiving only “recent cases” being supplied with every convenience and appliance for the cure of insanity, that it should be served by nurses, male and female, instead of “asylum attendants,” versed in every trick of their trade, and that the establishment should be under the direct and responsible management of a medical committee composed not exclusively of specialists, but including general physicians and surgeons, as well for the purposes of administrative control as the direct treatment of the inmates. Let this plan, which was strongly urged by our Commission in 1876, be adopted experimentally, and we can have no doubt of the beneficial result. It is a simple waste of public funds to go on building huge asylums which are refuges and nothing more.

THE SURGICAL AID SOCIETY.

THE annual meeting of the Surgical Aid Society was held on the 3rd instant, under the kindly auspices of the Lord Mayor, who evidently does not wish to judge severely any of the institutions of the country, from the House of Lords down to the Surgical Aid Society, which, however, is by no means the worst institution in the country, and would be a very valuable one indeed if surgical aid were not a necessary instead of being a mere luxury. The committee resent the criticisms that are constantly passed on them on account of their regulation requiring a number of letters, expressing in money value the cost of the particular appliance needed. It can be easily understood that this is a very irksome rule to persons who, with ruptures, or with the loss of one leg or of two legs—as in an instance quoted a few days ago—are greatly disabled for travelling over London to get the requisite number of letters. So great was this scandal that the Hospital Sunday Fund has had to go somewhat out of its way to do the work of the Surgical Aid Society in a more direct and easy manner, to the great delight of all cripples. The Surgical Aid Society think the charges against them sufficiently answered by saying that they have given their surgeons and secretary discretion to deal promptly with urgent cases, without waiting for the full complement of letters. Having done this much in the direction

of public opinion, they proposed somewhat warmly to decline any further “communication with the parties referred to.” At the instigation of the Lord Mayor these words were left out of the resolution expressing the confidence of the society in the administration by the committee—wisely, because “the parties referred to” are pretty synonymous with the public. We sincerely hope that the Surgical Aid Society will come to the conference arranged to be held in the spirit of the Lord Mayor, and of willingness to make such changes in its rules as common sense and humanity dictate.

THE WEATHER.

ALTHOUGH snow has been eliminated from the paraphernalia of an English Christmas, so effectually that even in the annuals snow scenes are sketched as in Russia or Canada, it must not be assumed that the weather is wholly unseasonable. We are just now subjected to a process even more trying than the ordeal by cold. On the whole, the temperature is warm, but the atmosphere, in London at least, is enervating. The weakly are tempted to run risks of exposure and fatigue, which may by and by produce a startling crop of evil consequences. It is not a gracious task or a thankful duty to prophesy disappointment and disasters, but we greatly fear that after this spell of “green weather” has past there will be more than the customary amount of heavy sickness, of an exhaustive type, in the community, and more especially in families and among individuals who, counting themselves healthy and the weather exceptionally genial, have not observed the usual precautions either as to the amount of exercise they take, the food they consume, or the avoidance of unduly late hours, and reckless exposure.

PUBLIC CONVENIENCES.

A REQUIREMENT which has long been felt by London pedestrians, especially those of the female sex, has been attempted to be supplied by a company formed for the purpose of providing public lavatories and retiring-rooms. The census of 1871 showed that some 300,000 women were engaged in pursuits which involved the necessity of being much out of doors. To this number, now largely increased, must be added those who, for purposes of shopping or of recreation, are frequently, and sometimes for considerable periods, away from home. To such the accommodation offered by the chalet supplied by the company referred to will often be most welcome. It is described as a light and handsome structure in wood, iron, or brick, of Swiss rustic style, and will include lavatory, retiring-rooms and other needed conveniences. There are obvious difficulties in the way of carrying out with efficiency a plan to meet the want indicated above, and previous attempts have resulted in failure, but it is absurd to suppose that the idea is impracticable.

THE HEALTH OF THE VICEROY.

WE trust repeated statements that the Marquis of Ripon is ailing first with “fever,” then with “sunstroke,” do not portend serious illness. He has thrown himself into his work with more than common energy, and it is quite possible that, relying on a robust constitution, his vigorous will may impel him to a course of action which must needs be hazardous. Even strong men require to observe moderation in their expenditure of brain and nerve force in India. It will be a cause of sincere regret in England if Lord Ripon, for whom we all feel much respect, and from whose official work in India we expect great and permanent results, should endanger his success by unwise zeal and too great enterprise. It would be better far to put the drag on a little than to risk a breakdown at this conjuncture.

ALLEGED POISONING BY CHLORODYNE.

THE death of Thomas Pash, aged sixty, of Oxley-street, Bermondsey, with all the symptoms of narcotic poisoning, after taking several doses from a bottle marked "Dr. J. Collis Browne's Chlorodyne," and the verdict of the jury of "Death by misadventure from an overdose of chlorodyne," open a very important question. Chlorodyne, it is alleged, contains morphia in very large quantities (according to Dr. Browning some varieties contain as much as ten grains to the ounce !), and yet it is not included under the provisions of the Poisons Act, and is sold indiscriminately to the public with the pseudo-guarantee of safety and value which the Government stamps afford. The infant mortality, directly or indirectly, due to so-called "soothing remedies" is probably enormous, and no one can say how many adults owe their death to the ignorant use of patent narcotic remedies. Now that we have a Public Prosecutor such questions certainly ought not to be allowed to rest, and we should hope that the sale of any of the articles mentioned in the Poisons Act, without compliance with the terms of the Act, will be looked upon as a contravention of the Act, and be punished accordingly. This vending of secret preparations is a condition of things which calls for instant remedy, and the only remedy, we believe, is to absolutely disallow the sale of any articles of consumption (whether dietetic or therapeutic), the composition of which is not fully and accurately stated on the bottle or packet.

RABIES.

A *RABID* retriever (according to the *Leeds Mercury*) committed terrible ravages in the neighbourhood of Leeds a few days ago, in the early morning when people were going to work. It was still dark, and the movements of the dog could not be well distinguished; most of those bitten were attacked unawares. The animal approached one man from behind, jumped up to the back of his head, but failing to get a hold there it sprang at him a second time and seized him by the thigh. The dog then rushed on, snapping and biting everyone whom it approached. One man was walking down the street when the dog rushed at him from behind with such violence as to throw him on his face, and in that position commenced to worry him, and the poor fellow was severely bitten on his legs before he could make his escape. One man obtained a bar of hot iron with which to kill the dog; but while he hesitated to strike, being in doubt as to whether it was the same animal, the dog rushed at him, and bit him severely in the finger and thumb. At least twenty persons had been bitten when a policeman, who had been pursuing the dog, attacked it with his staff, and ultimately succeeded in killing it with a poker. During the last month the borough police captured in Leeds no fewer than 287 stray dogs.

PULMONARY REFLEXES.

ACCORDING to Dr. Sommerbrodt of Breslau every increase of the intra-bronchial pressure, in loud speaking, singing, cough, exertion, or the inhalation of compressed air, causes stimulation of sensory nerves of the lung. From this there results a reflex depression of the vaso-motor nerves, shown in a diminution of the vascular tone, dilatation of the vessels, and fall in the blood-pressure. There is also a reflex depression of the cardiac inhibitory nerve, which is the cause of the increased frequency of action of the heart. Both these effects lead to an increase in the rapidity of the blood-current, and a consequent increase in the secretion of urine. The effect of these reflex actions is to over-compensate for the obstruction to the circulation which the increased intra-pulmonary pressure causes, and to provide an increased supply of oxygen, &c., to the muscles which

are in functional activity, and also to the central nervous organs. The stimulation of these nerves will, moreover, alter the rhythm of the heart's action. Knoll found that in animals increased arterial pressure was capable of causing a retardation in the action of the heart, and a bigeminal pulse; according to Sommerbrodt, the same effects are demonstrable in man.

SEA-WATER BATHING IN LONDON.

ONE of our humorous contemporaries a few days ago depicted a London backyard arranged with all the appliances of a sea-coast bathing station barring the beach and the sea, and the family, accurately appraised in bathing-costumes, going gravely through the various procedures of bathing according to their taste and fancy, while paterfamilias, enjoying himself with the rest, was further rejoicing in the fact he need no longer take his family to the sea, but that the sea by a much less costly process was being brought to him. The burlesque threatens to become in some sort a truth, for notice has been given of a Bill being brought before Parliament for the incorporation of a company to bring sea-water in pipes, &c., from Lancing, in Sussex, to Victoria-street, Westminster, with branches that will admit of its distribution in many parts of London.

SECONDARY MUSCULAR CONTRACTION.

ACCORDING to M. Ch. Richet, if the fresh muscle of a crayfish is taken and extended by a slight weight, and the muscle is then stimulated for one or two seconds by strong and frequent induction currents, the muscle relaxes as soon as the stimulation ceases. But this relaxation is not final. After some seconds, although there is no fresh stimulation, the muscle contracts afresh, and returns more or less completely to its previous tetanic contraction. This lasts nearly half a minute, and at the end of one or two minutes it is finally and completely relaxed. In favourable cases it may be noted that this secondary contraction comes on by successive rhythmical and progressive waves. It does not occur if the stimulation has been slight, if the muscle is fatigued, or if the weight is too great. It is probable that this secondary contraction always occurs, but cannot be registered unless it is of a certain degree of intensity. It explains how it is that successive stimulation renders the muscle more and more sensitive.

ON December 5th, 1880, Mr. Hughes, of Plymouth, amputated at the right hip-joint in a girl, aged seven, for extensive disease of the head and shaft of the femur. The girl could ill afford to lose any blood, as the disease had existed for eighteen months, and her urine was albuminous. Dr. A. H. Bampton, house-surgeon to the South Devon and East Cornwall Hospital, controlled the hæmorrhage with the greatest ease by means of Davy's lever; only three ounces of blood were lost, principally venous, and what was necessary to enable the operator to see where the arteries were. The operation was not performed under the spray, on account of the sinuses. The abdominal aortic tourniquet was quite inapplicable in the present case. Mr. Jackson, F.R.C.S., and Mr. Edlin assisted. The girl is progressing favourably.

IN consequence of the general and strong feeling among the friends of Mr. G. D. Pollock that the occasion of his retirement from the position of Senior Surgeon to St. George's Hospital is an appropriate opportunity for some public recognition of his eminence in the profession and the kindness and rectitude of his character, a meeting of Mr. Pollock's colleagues and some other friends has been held, at which it was decided to call a public meeting, the date of which will shortly be announced for the furtherance of this object.

AT the final meeting of the Dublin Mansion House Relief Committee, held last Tuesday, a resolution was adopted that a grant of £150 each be made to the families of Drs. Donovan and Robinson, of Skibbereen, and Greely, of Oranmore, who died of fever in the discharge of their duty as dispensary medical officers. We understand that Mr. Gladstone has recently forwarded £150 from the Royal Bounty Fund to the family of Dr. O'Donovan, and £250 to the family of Dr. Robinson.

A SERIOUS defect in the construction of the building of the Woodford Convalescent Home has come to light. Owing to some accident connected with the pipes, dry-rot has, it seems, gone far to destroy the beams supporting some of the ceilings. The timely discovery of the damage done, the repair of which will involve considerable expense, has probably averted a terrible calamity. The home shelters nearly 160 patients.

A COMPLETE return of the collections for the Dublin Hospital Sunday Fund has not yet been issued, but from the amount already acknowledged, a considerable falling off may be expected as compared with the preceding year. The depression in trade and the land agitation are causes, however, which will sufficiently explain decrease in the sums to be distributed among the Dublin Hospitals on this occasion.

At a meeting of the members of the Brixton Medical Book Society, held on Friday, Dec. 3rd, it was unanimously resolved:—"That this meeting desires to express its sympathy with Dr. Habershon and Mr. J. Cooper Forster in their retirement from their positions on the staff of Guy's Hospital, and their appreciation of the self-sacrifice which they have shown in support of the dignity of their profession."

At a large and representative meeting of the students of Queen's College, Cork, the following resolution, we learn, was unanimously adopted:—"That we, the students of Queen's College, Cork, do hereby express our disapproval of the conduct of Dr. Charles in requesting medical students of Dublin University to withdraw from the dissecting room, which they had been invited to visit by the Cork medical students."

THE death of Mr. Robert Thomas, L.S.A., medical officer of health for Rawdon, is announced in the local papers. The deceased was seventy years of age, and had been a great part of the night of Dec. 1st in attendance on a patient. In the morning his housekeeper found him sitting in a chair in his surgery quite dead.

WE learn that Dr. S. O'Sullivan, of Cork, has been appointed by the Government to the vacant Chair of Surgery in Queen's College, Cork. Dr. O'Sullivan is a graduate in Medicine and Surgery of the Queen's University in Ireland, and the appointment made is one which may be regarded with satisfaction.

A CASE of some importance was decided this week in the Oldham County Court. Dr. Thomson sued a party for professional attendance. The judge, looking at the bill, observed that no items were furnished, and, in consequence, allowed only one-half of the amount claimed.

At a meeting of the Medical Society of the College of Physicians in Ireland held last week, a resolution of condolence with the family of the late Dr. Hudson was adopted. Dr. Hudson was an honorary member and ex-president of the society.

It is stated that Dr. Grimshaw, Registrar-General for Ireland, recently received a letter threatening his life unless he dismissed a gardener whom he employed, and that he is now under police protection.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Gravesend.—Dr. J. H. Gramshaw's report on the health of Gravesend for the year 1879 shows an exceedingly healthy condition of the 24,000 inhabitants who are estimated to have occupied this highly favoured locality, "dear to the hearts of vagrant Londoners, during the period in question. The death-rate for the year barely exceeded 15 per 1000 of the population, and only five deaths from diarrhoea occurred in the twelve months, a remarkable falling off in the mortality of this disease, which Dr. Gramshaw attributes to the efficient sanitary administration which now obtains in the place. "Those who remember the town ten years ago," he says, "must readily bear witness to the improvements which have taken place, not only in the main streets, but in those close, ill-paved, and badly-ventilated purlieus where disease always abounded." The town also now possesses an abundance of pure water, that its refuse is more efficiently removed, and that it is more systematically cleansed. If it were only systematically drained and freed from the stinks from heaps of London manure brought into its vicinity for the convenience of farmers, Gravesend, according to Dr. Gramshaw's account, need not blush even if it were next door neighbour to Hygeiaopolis.

Islington.—In his report for 1879, as medical officer of health for this metropolitan district, Dr. Meymott Tidy has happily little more to do than present a formal statement of its healthiness, as measured by the mortality. The death-rate for the year is estimated at 19.1 per 1000 population—a death-rate not varying from that of the previous year. Measles was the principal epidemic during the year, 219 deaths from this disease being recorded; while small-pox, "more or less prevalent throughout London," caused only 7 deaths. But on these deaths Dr. Tidy observes:—"Although it is true the deaths recorded in the table from small-pox are few, nevertheless it is important to bear in mind that the prevalence or not of small-pox in any given district cannot be accurately gauged by the mortality alone. And the reason of this is obvious—viz., that it is the one disease where so soon as it makes its appearance patients of the poorer, and even middle classes, are removed to hospitals. Thus a parish may apparently be, so far as death returns indicate, actually free from the disease, whilst all the time patients are being removed to the various hospitals fitted for their reception. No more important sanitary question can occupy the minds of our legislators at the present time than the paramount necessity of not only registering deaths, but of registering cases of sickness as well. It is the absence of this information that makes sanitary work difficult; and the public cry of the neglect of sanitary authorities most often means that they do not possess the necessary information on which they can act, because our laws have given them no power to obtain it. And, in illustration of this, the hiding up of local outbreaks of infectious disease affords the best possible illustration."

Whitechapel.—Mr. John Liddle's report for the quarter ending Oct. 2nd shows that in his district the weekly average of births was 45.3 and of deaths 42.7, as compared with 50.6 and 40.9 in the corresponding quarter of the previous year. The deaths of children under one year of age formed 24.8 per cent. of the total mortality. Differing from most medical officers of health, Mr. Liddle expresses an opinion that the discrimination of typhus from typhoid fever is of less importance in sanitary than in medical practice. He holds, moreover, that the privies in the poorer neighbourhoods of Whitechapel should be provided only with pans and traps, and should be flushed by hand—that is, by pails of water thrown into the pans once or twice a day. He objects to fixed apparatus for flushing (service cisterns, &c.) on account of

the destructiveness of the people in the poorer neighbourhoods; but he says nothing of the sort of inspection required to keep the paucers reasonably clean with a system of hand-flushing, although elsewhere such a system has been found an unmitigated evil unless regularly supervised by the sanitary authority.

THE HEALTH OF NORTH ORMESBY.

At a recent meeting of the Ormesby Local Board, the medical officer of health, Dr. Sleightholme, presented a special report on the health of the place, in which he formally contradicted several statements prejudicial to it which had lately gained currency. He observed that these statements were entirely without foundation, and said that the mean annual death-rate of Ormesby during the last six years had been 19·5 per 1000 population, and during the last four years 16·7. Typhoid fever, once common in the district, is now a very rare disease. He concluded his report by the following summary statement:—"1st. That during the four years ending December 31st, 1879, the sanitary state of the district was highly satisfactory and the death-rate very low. 2nd. That in the present year, and in the last two months of the past year, a severe epidemic of scarlatina has been present in the district, and that this epidemic ceased early in September. 3rd. That there are no circumstances in the district which would induce me to think that in the next four years the mortality of the district will be above that of the four years immediately preceding the present year."

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES IN DUBLIN.

A number of medical gentlemen interested in this subject had a conference with the Lord Mayor and Corporation of Dublin on the 2nd inst. The matter had been previously before the Town Council, who had a difference of opinion as to whether the notification should be given by the householder or by the medical attendant. The Council of the Dublin Branch of the British Medical Association, who initiated the project, wished that the duty of declaring that an infectious disease existed in a household should not be thrown on the medical attendant but on the householder; but from the discussion which took place last week at the Town Hall, it is evident that the majority of the speakers consider that if the compulsory notification of infectious diseases is to be thoroughly successful it must be carried out by the practitioner in attendance, and not left to the head of the family where the contagious disease exists. A deputation from the Corporation of Dublin had an interview with the Chief Secretary on Wednesday, the 8th inst., on this subject.

THE HEALTH OF PRESTON.

"Why should it be that the proportion of infant deaths in Preston is nearly double that of a town like Oldham? What is there inimical to young life in the domiciliary arrangements and surroundings of Preston which causes 700 or 800 infants to die here in a year, who, if they had the luck to be born in Oldham, would not die?" So questions the *Preston Guardian*, and we think that we may safely promise our contemporary that if he will institute an inquiry, by a commission appointed for the purpose, into the intimate sanitary state of the town, and into the doings of the sanitary authority for a few years back, he will soon obtain a clue to the difficulties which now perturb it. If, moreover, he would give the report of such a commission freely and frankly to the public he would confer an incalculable benefit on the town.

A CONFUSED LOCAL AUTHORITY.

The District Board of Works of Woolwich is evidently under the impression that it rests with itself to appoint or not appoint a medical officer of health, or to use the Poor-law medical officers to do medical officers of health's duties, or to impose those duties on its inspectors of nuisances or other sanitary officials. Its doubt as to the law of the matter is an indication of its confusion with regard to the functions to be exercised by the several sanitary officers. If this be the condition of things at Woolwich with regard to so comparatively a simple matter as to the appointment and duties of officers, what must be the state of sanitary administration in the place?

INFECTIOUS DISEASE HOSPITAL PROVISION AT SALFORD.

It would appear from a recent report of the Corporation of Salford that they have made provision, partly in the borough and partly with the fever hospital belonging to the Manchester Royal Infirmary, for accommodation for no less than 220 patients suffering from infectious disease, the population of the borough being under 200,000. This is an admirable example to have set. The hospital within the borough, known as the Wilton hospital, had received during the year ending September 30th, 1880, 496 patients, of whom 254 had been sent by the Poor-law Guardians, the latter contributing £1138 to their maintenance.

SLIGO WATER SUPPLY.

The Sligo Corporation has received a communication from the Local Government Board (Ireland), stating that they have recommended a loan of £28,000 to be lent them as the sanitary authority by the Board of Works, for the construction of the proposed waterworks for that town.

Maidstone is evidently a remarkable place, sanitarily considered. Last week we had to announce that it had spent £50,000 in the production of two cases of typhoid fever; now we have to state that the local board is proposing to memorialise the Home Secretary (!) in favour of precautions being taken against the danger to the public health arising from the importation of rags which may contain the germs of disease, Maidstone being so favourably situated in its position and county, and so isolated from personal communication with the rest of the world, that several cases of "disease" (infectious, we presume) which have lately occurred there, notably small-pox, could only (it is locally believed) have come there by importation of the contagion in the rags brought into the neighbourhood for the paper manufacturers.

Sir Sydney H. Waterlow has written to the Home Secretary correcting a statement made in a memorial addressed to that Minister by several vestries and district boards in the metropolis, in which it is stated that the Improved Industrial Dwellings Company, Limited (of which Sir Sydney is chairman), had made no offer for any of the sites cleared under the Artisans and Labourers' Dwellings Improvement Act, 1875. Sir Sydney says that this statement is an error, and that his company has over and over again tendered for sites for workmen's dwellings under the Metropolitan Street Improvement Act, 1872, but that none of their offers have been accepted "although seven or ten sites set apart by Parliament are still uncovered, and, in addition to being a heavy loss on the rates, are dreary and unsightly wastes."

The difficulty of dealing with irregular practices in trade is curiously illustrated by a fact stated in the last report of the medical officer of health (Dr. Sedgwick Saunders) of the City of London to the Commissioners of Sewers. It appears to be the practice of the licensed salesmen in the Central Meat Market to allow the licensed porters of the market and journeymen butchers to sell meat of an inferior description—offal and odds and ends—to their own profit in the licensed shops after the legitimate business of the market is over. Thus a most discreditable trade in meat of dubious character has been established under the licensee's cloak.

Poplar, we learn, is congratulating itself on the prospect of its new infectious disease hospital being taken off its hands by the Metropolitan Asylums Board. The District Board of Works having sacrificed so conspicuously to sanitary virtue in building the hospital, and placed itself on the highest pitch of fame in this respect among metropolitan sanitary authorities, is now prepared to rid itself of the troublesome responsibility of maintaining the hospital, and is eager to seize upon the opportunity of turning a honest penny by it.

The Metropolitan Board of Works is about to discuss the question of selling the carcasses of animals affected with pleuro-pneumonia for human food. The *Metropolitan* anticipates the discussion of the Board, and settles, very much to its own satisfaction, and doubtless to that of, at least, one section of its readers, that "the evidence is conclusive that no harm arises from the consumption of the flesh of such carcasses, unless it exhibit signs of disease or degeneration in itself."

Dr. Rogers, the medical officer of health for Limehouse, reporting to his authority the reappearance of small-pox in the district, said that in one instance he found that the disease had appeared in a house where a laundress resided. At the time there were on the premises no less than 600 articles of clothing belonging to a school. He had impounded them, and after they were washed he proposed to pass them through the authority's disinfecting apparatus.

A very unpleasant report comes to us from Leicester of the discharge of a female patient suffering from "fever" from the Leicester (Corporation) Fever Hospital, while in a state of "insanity," and of her being removed first to a brother's home, and then to the lunatic asylum, into which she was admitted "covered with sores, and in a very filthy condition." As the case will be the subject of an inquiry, we suspend remark for the present.

A plan for the disposal of the sewage of the Rhondda Valley has, it is stated, received the approval of the Ystrad-yfodwg and Pontypridd Urban Sanitary Authority. The scheme is estimated to entail a cost of £10,000, a sum which has excited the alarm of the ratepayers of the district, and provoked active resistance to the proposal.

An inquiry is proceeding, conducted by Dr. Bridges, under instructions from the Local Government Board, into a disagreement which has occurred between the medical officer and assistant medical officer of the St. George's-in-the-East Workhouse Infirmary. We postpone an account of the inquiry until it is completed.

The Bethnal Green Sanitary Authority recently applied for, and obtained from, the sitting magistrate at Worship-street, an order to remove four children suffering from small-pox to the Homerton Hospital who were lying in a room occupied by six other persons, and whose parents objected to their removal.

The Kensington Board of Guardians, with the assent of the Local Government Board, have purchased, at a cost of £56,000, the premises belonging to the Vestry of St. Margaret and St. John, Westminster, adjoining their present infirmary, for conversion into a new infirmary.

A serious epidemic of measles is reported to be prevailing in Frome. A suggestion to close the schools, made at the last meeting of the board of guardians, was, however, not acted upon, on the ground that the crisis of the outbreak was past.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4968 births and 2961 deaths were registered last week. The births were 217, and the deaths 314, below the average weekly numbers during 1879. The deaths showed a decline of 214 from the number returned in the previous week; and the annual death-rate per 1000, which had been equal to 21·2 and 22·1 in the two preceding weeks, declined last week to 20·6. The lowest death-rates in the twenty towns last week were 13·6 in Brighton, 14·4 in Wolverhampton, 16·9 in Bristol, and 18·1 in Sheffield and Plymouth. The rates in the other towns ranged upwards to 24·0 in Nottingham, 24·3 in Norwich, 24·8 in Hull, and 25·5 in Sunderland. During the first nine weeks of the current quarter the death-rate in these twenty towns averaged 22·1 per 1000, against 22·9 and 22·1 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 367 and 405 in the two preceding weeks, declined to 358 last week; they included 139 from scarlet fever, 72 from measles, 58 from whooping-cough, and 40 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2·5 per 1000 in the twenty towns, and ranged from 0·7 and 1·0 in Wolverhampton and Sheffield, to 4·8 and 6·7 in Salford and Sunderland; no zymotic death was recorded in Brighton. The fatal cases of scarlet fever, which had been 138 and 162 in the two previous weeks, declined again to 139 last week, and showed the largest proportional fatality in Sunderland, Leicester, Bradford, Liverpool, and Leeds. Measles fatality was largest in Salford, and that of whooping-cough in Hull

and Nottingham. The highest death-rates from fever, principally enteric, were recorded in Leeds and Leicester. The 15 deaths from diphtheria showed a further decline from recent weekly numbers; 10 occurred in London, 3 in Birmingham, and 2 in Portsmouth. Small-pox caused 10 more deaths in London, whereas no death from this disease was registered in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased in the five preceding weeks from 77 to 210, further rose to 246 on Saturday last; and 67 new cases of small-pox were admitted to these hospitals during last week, against 99 and 57 in the two preceding weeks. The number of patients in the Highgate Small-pox Hospital had also further increased to 21 on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 332 and 367 in the two preceding weeks, declined again to 334 last week, and were as many as 170 below the corrected weekly average; 210 resulted from bronchitis, and 87 from pneumonia. The annual death-rate from lung diseases was equal to 4·9 per 1000 in London, and 7·6 in Liverpool.

In the twenty towns last week 60 deaths were registered without the production of the certificate either of a registered medical practitioner or of a coroner; these were equal to 2·0 per cent. of the total deaths registered. The proportion of uncertified causes of death did not exceed 1·4 per cent. in London, whereas it averaged 2·6 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Brighton, Portsmouth, Norwich, Plymouth, Wolverhampton, or Nottingham, while the largest proportions occurred in Sheffield, Sunderland, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 22·1 per 1000, against 20·9 and 24·7 in the two preceding weeks, and was 1·5 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 15·6 and 16·8 in Perth and Dundee, to 26·7 and 42·5 in Leith and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 95 and 112 in the two previous weeks, declined to 95 last week; they included 34 from scarlet fever, 16 from diphtheria, 16 from diarrhoea, 12 from fever, 8 from measles, 8 from whooping-cough, and one from small-pox. The annual death-rate from these seven diseases averaged 3·8 per 1000 in the eight towns, and exceeded by 1·3 the average rate from the same diseases in the twenty English towns. In the eight Scotch towns the zymotic death-rate last week ranged from 1·0 and 2·0 in Aberdeen and Dundee, to 5·9 and 8·0 in Greenock and Leith; no zymotic death was registered in Perth. The fatal cases of scarlet fever in the eight towns, which had been 53, 45, and 37 in the three preceding weeks, further declined last week to 34, of which 14 occurred in Glasgow, 12 in Edinburgh, and 7 in Leith. The 16 deaths referred to diphtheria exceeded the numbers returned in recent weeks, and included 4 in Glasgow, 4 in Edinburgh, and 3 in Greenock. The 16 deaths from diarrhoea again showed a marked excess for the season; 7 occurred in Glasgow, 3 in Edinburgh, and 3 in Paisley. The total deaths from fever showed an increase of 2 upon the number in the previous week, and included 5 in Glasgow, 3 in Edinburgh, and 2 in Greenock. Seven of the 8 fatal cases of measles, and 5 of the 8 of whooping-cough, were returned in Glasgow. The death from small-pox was recorded in Greenock; this is the first fatal case of this disease that has occurred in these eight Scotch towns since the middle of July. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 137 and 166 in the two preceding weeks, were 155 last week. The annual death-rate from these lung diseases was equal to 6·3 per 1000 last week in the eight Scotch towns, against 4·3 in London; the highest death-rates last week from these diseases in the Scotch towns occurred in Paisley, Greenock, and Glasgow.

HEALTH OF DUBLIN.

There was a considerable decline in the excessive death-rate in Dublin last week. The annual rate of mortality from all causes in the city, which had been equal to 39·6, 33·3, and 37·8 in the three preceding weeks, declined last

week to 29·8, a lower rate than has prevailed in any week since the end of July last. During the past nine weeks of the current quarter, however, the death-rate in the city has averaged no less than 34·3 per 1000, against 21·3 in London, and 22·3 in Edinburgh. The 180 deaths in Dublin last week showed a decline of 48 from the number in the previous week, and included 28, or 16 per cent., which were referred to the seven principal zymotic diseases, a decline of 14 from those returned in the previous week; 10 resulted from fever (including typhus, enteric, and simple), 7 from scarlet fever, 4 from measles, 3 from whooping-cough, 2 from diarrhoea, 2 from small-pox, and not one from diphtheria. The annual death-rate from these zymotic diseases was equal to 4·6 per 1000 in Dublin last week, against 2·6 in London and 5·2 in Edinburgh. The deaths referred to fever, which had been 10 and 17 in the two preceding weeks, declined again to 10 last week; but the death-rate from this cause was no less than six times as great as the average rate in the twenty English towns last week. Fever, mainly typhus and enteric, has been especially fatal in Dublin since the beginning of this year. The 7 deaths from scarlet fever in the city last week showed a decline of 4 from those in the previous week, while the fatal cases of small-pox and measles corresponded with the numbers then returned. The deaths of infants in the city were fewer than in any previous week of the year, while those of elderly persons were again excessive.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

BACKERGUNGE GAOL.

Backergunge Gaol has a sort of horrible reputation in Bengal for unhealthiness, especially for cholera and dysentery. The sanitary advisers of the Indian Government and the Army Sanitary Commission have been much exercised with the place, and have advised the expenditure of considerable sums of money in the reconstruction of barracks, and no little ingenuity has been exercised in accounting for the unwholesomeness of the gaol by its geographical position. But it would appear that while measures were ineffectually based upon vague speculations as to occult causes, probable causes lying under the nose were unheeded. A correspondent of the *Pioneer*, under the familiar signature of "Scrutator," tells us that in 1878 drinking-water was ordered to be brought from the Burrisal river, but on close examination it was found that it really came from the mouth of a small tidal nullah just at the point where it discharged into the Burrisal river. The town of Burrisal stands on this nullah, and the water for the prison was taken a couple of hundred yards below the town. This nullah is, in fact, the sewer of the town. When the water reached the interior of the prison, it underwent filtration through chatty filters, and this process was evidently superintended with constant and unremitting attention. But the result was only partially successful, for a very considerable amount of opalescence remained in the water. But there soon appeared reason to doubt whether the convicts really used this elaborately filtered water at all, for a large party of them were seen coming into the prison by a side door, each provided with a *lotah* of water, which proved on inquiry to have been taken from a tank on the gaol premises in which the convicts bathed, and which communicated with the tidal nullah before mentioned, or in other words the sewer of Burrisal. The convicts said that the tank water was very good, though every tide must have washed quantities of impurities into the tank. Such was the water-supply which official reports, written by men of ability, the clearness of whose mental vision had been obscured by old Indian prejudices, described as good. "This case conveys a warning," says "Scrutator," "as the defects of the Backergunge Gaol water-supply—the worst I have ever seen in the course of a pretty wide experience—have been so long overlooked, notwithstanding the earnest efforts of the Government at any cost to abate the unhealthiness of the prison. Is there not reason to apprehend that less obvious defects in the water-supply arrangements of the European troops may have escaped notice, and that to those defects, as surmised by the theorists against whom the Army Sanitary Commissioner lately warned the Government, may be due the calamities which have lately occurred at Allahabad and other places, and in which cholera proved destructive to a greater portion of our gallant soldiers than fell under the bullets of the Afghans throughout the late war."

"ACUTE ANÆMIC DROPSY."

We have received a copy of a supplementary official report on "Acute Anæmic Dropsy," from Mauritius. The report contains a copy of Surgeon-Major K. McLeod's report, as Health Officer of Calcutta, on the subject of the "new disease" that has lately appeared in that city, which has been held to be "beri-beri," and believed to be similar to the so-called "acute anæmic dropsy" of Mauritius. The additional information contained in this supplementary paper goes far to traverse this notion, and tends to the conclusion that the disease in Mauritius is not beri-beri, and to throw doubts upon the "new disease" in Calcutta being beri-beri; also that "acute anæmic dropsy" was introduced into Mauritius probably by emigrant coolies from Calcutta, and that it is a contagious affection. Judgment, however, must still be suspended on these questions, and we wait further and fuller information.

PLAGUE IN RUSSIA.

A rumour has been current in Vienna that plague had appeared in the neighbourhood of Moscow. A similar rumour obtained during the outbreak of the disease in the Lower Volga in 1878-79, and we trust that the rumour may prove as unfounded now as it did then. The disease, whatever it may be, is said to be highly contagious, and not improbably true typhus may be in question, a disease which has been recently somewhat widely distributed in Russia, we believe. The dearth of medical men is so great in the country districts in Russia, that it may be some time before the actual meaning of the rumour is brought to light.

St. Lucia and Gaudaloupe are now stated to be free from yellow fever, and the quarantine restrictions, which have been very detrimental to the interests of trade in the Antilles, have been removed.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Brigade-Surgeon Wm. Carden Roe has been granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major James Watson is granted retired pay, with the honorary rank of Brigade-Surgeon.

Brigadier-Surgeon Wolseley, Surgeon-Major Graves, and Surgeon Smythe, of the Army Medical Department, have taken passage to Bombay to join their respective corps.

MILITIA MEDICAL DEPARTMENT.—Surgeon Major Wm. Ord Mackenzie, the Highland Rifle Militia, resigns his commission; also is permitted to retain his rank, and to continue to wear his uniform on retirement.

ADMIRALTY.—Surgeon Henry Beaumont, to be staff Surgeon, with seniority of the 1st of December, 1880; Surgeon William Tait, M.B., to the *Téméraire*, when commissioned; Staff-Surgeon James H. Martin to the *Indus*, in lieu of a surgeon; Staff-Surgeon Eugene V. de Méric, to the *Boscawen*, additional, for sick quarters at Portland; Surgeon Henry R. Guppy to the *Royal Adelaide*, additional, for temporary service; Surgeon H. L. Crocker to Plymouth Hospital.

Correspondence.

"Audi alteram partem."

ON MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—Mr. Savory's letter opens a question for discussion which cannot fail to interest every teacher in our medical schools. I can scarcely yet bring myself to admit the necessity of an extension of the students' hospital work for seven years, and chiefly on these two grounds:—

First, because it does not appear that the advantages held out to medical men and the incomes derived from their profession are sufficiently great to justify a lengthening of study so extreme. Nor is there any reason to believe that the public would be prepared to pay more highly for even

decidedly better practitioners than are supplied to it at present.

Second, because I do not fear to challenge that army of champions which Mr. Savory predicts will rise when a proposal is made to remove or limit any single subject of medical study. I have never yet understood why the study of botany is compulsory in our schools. Nor do I know why it is thought essential that practitioners should be acquainted with the histology of all the tissues and organs of the body. I should be glad to see the first of these subjects removed from the curriculum, the second strictly limited. I would suggest, too, a limitation of the range of anatomy, physiology, and chemistry, and the publication of a syllabus stating the exact amount of each required by the student. Further, I have hitherto failed to comprehend the precise advantage which students are supposed to gain by having learned in lectures or from a book how to prepare the various salts, and, worse still, the alkaloids employed in medicine.

If the object of medical education is to produce good average medical practitioners, and the time now bestowed upon the work is insufficient, the first direction which reform should take is to sweep from the curriculum all work which does not tend *directly* to that object. I leave it to those who teach these subjects to prove how far they are essential, and remain, Sir, yours obediently,

HENRY T. BUTLIN,

Assistant-Surgeon and Demonstrator of Surgery,
St. Bartholomew's Hospital.

Dec. 7th, 1880.

To the Editor of THE LANCET.

SIR,—Mr. Savory's cry, "Give us more time," will be echoed by every teacher who has the welfare of the student at heart; but, as he says, the obstacle is the increase of expense which will be necessary were the curriculum prolonged. I wish to point out, however, that the difficulty would be greatly met were the council of the College of Surgeons to modify its regulations, and require two full years to be passed in the study of medicine, surgery, and midwifery *between* the first and second examinations.

Theoretically this is the case at present, and a hard-working student who passes his primary or anatomical and physiological examination at the end of his second winter has then two winters and three summers for the study of the practical subjects of his profession before he goes up for his diploma. But the majority of students do *not* pass the primary examination in their second year at all; many go on to their third, some to their fourth, and a few to their fifth year before they scrape together enough anatomy and physiology to pass. In the meantime their lectures on medicine, surgery, and midwifery are all duly sat out, and by a pleasant fiction their hospital practice and clinical study run on contemporaneously, so that, six months, three months, or even only a week, after passing the primary examination, a candidate (who has completed his four years' study and got his schedule in due order) may present himself for two diplomas, and possibly obtain them!

A regulation that two years *must* elapse between the first and second examinations would prevent this scandal, and if permission were given that six months of this time might be spent in a country hospital, or with a qualified practitioner, the regulations allowing such attendance before entry at a medical school might be advantageously revoked.

Yours obediently,

CHRISTOPHER HEATH.

Cavendish-square, W., Dec. 7th, 1880.

To the Editor of THE LANCET.

SIR,—In a letter on the above subject Mr. Savory seems to think that the lack of knowledge possessed by many members of our profession is due to want of time spent in study and hospital practice. He is, I believe, right to a certain extent, but our examinations and the so-called higher ones are responsible for very much practical ignorance of ordinary duties. There are many men in London who give six, seven, or more, years to acquire a competent knowledge of their profession, and, naturally wishing to have some diploma to show they have done so, turn their attention to the F.R.C.S. or the London University. But what is necessary to pass either of these boards? A gigantic system of cram-

ming—taking the Fellowship, and speaking of so-called Surgery only. Each candidate who wishes to pass takes care to make himself as familiar as possible with the pet questions of the examiners, and as there are several gentlemen at the college, and their whims various, much time is wasted. Thus one examiner is fond of asking the structure of a lymphatic gland; another thinks highly of the treatment of lacrymal stricture by styles; certain laugh at a good deal of the "antiseptic treatment," whilst others like to hear it praised. The examination itself is, to a certain extent, a lottery; for I have known good house-surgeons and demonstrators of anatomy, &c., rejected. The operative surgery this last time bears the chance character of the examination out; for I was told, on very good authority, that about twenty-four candidates had each two operations, and as there were only two bodies such a trifling operation as an amputation of a finger could obtain the same number of marks as a colotomy! Judging by the results of the last few examinations, it has been a rule to reject about half of those who presented themselves. What effect has this upon the unfortunate ones, and so upon the profession? An extremely bad one in the majority of cases, for rejection only serves to them as a stimulus to obtain the diploma. They study afresh those minute points which please their examiners and carefully give their undivided attention for at least a whole twelvemonth to this single subject, surgery, and most limited surgery too—in fact, to that part of it represented by their examiners; for if we leave out two very recent gentlemen added to their body, both of whom are engaged in ophthalmic work, and one of these two, who is an authority on skin diseases, would any general practitioner venture to consult any one of them on such ordinary matters as ulceration of the vocal cords, inflammation of the membrana tympani, disease of the choroid, or psoriasis? I say nothing about craniotomy, which I suppose is not a surgical operation. It is very certain that scarcely any "hospital surgeon in London" would be called in to do it. Thus failure at the examination almost forces a candidate to tie himself for a long time to a very small branch of his profession. What does success lead to? Often good hospital appointments. I will take those attached to one of our largest and most famous metropolitan hospitals. For years past I have constantly noticed that a physician has to be called in to see if the presence of tubercular diseases of the lungs negatives an operation, an ophthalmic surgeon to diagnose hypermetropia after receiving an injury of the head, an obstetric physician to help with an uterine fibroid, &c. Thus failure or success often means wasted time and but a very small knowledge of the "healing art." What should be the remedy? Students who have successfully passed such examinations as the M.R.C.S. should be encouraged to remain longer at our hospitals by the prospect of obtaining some higher diploma without being obliged to ruin such valuable time by cramming for examinations.

I am, Sir, yours obediently,

Dec. 7th, 1880.

Z. Y. X.

CHIAN TURPENTINE AND THE MIDDLESEX HOSPITAL.

To the Editor of THE LANCET.

SIR,—There is, perhaps, nothing remarkable in the medical board of the Middlesex Hospital adopting a resolution in the following terms: "That as the results of a prolonged and careful trial of Chian turpentine in the treatment of cancer prove the drug to be quite useless as a cure for that disease, directions be given to the dispenser not to obtain any more of the drug for the cancer patients." But as the resolution has been extensively published in the medical press, I must be allowed to say that it seems to point to a prejudice against the Chian turpentine treatment, not justified by the facts disclosed in the cases recorded in the last two numbers of the LANCET by Mr. Morris, who is the honorary officer of this department at the Middlesex Hospital. Mr. Morris heads his paper "On Chian Turpentine and its uselessness in Cancer," and, therefore, goes further than the resolution of the medical board, who have only declared the drug useless as a cure. The uselessness of the drug is the point at issue, as I have never yet affirmed it to be a positive cure for cancer, but have simply expressed my belief that it is possible by its

aid to formulate a plan of treatment for the removal of cancer in certain forms of that disease in the uterus.

To do Mr. Morris justice, no fault probably can be found with the manner in which he has executed the task of publishing his cases, for the honesty and candour he displays cannot but be commended; but it would have given greater satisfaction to myself, and I think also to the profession, if the cases selected by him for experiment had been worthy of equal approval, so that the experiments could have been conducted on a purely scientific method, and perhaps more in accordance with the "tradition" of the Middlesex Hospital trust. From such a selection of cases as Mr. Morris gives no one could be surprised at the results obtained. It was never contemplated by me that the remedy should be used in the treatment of cases verging on death, as five of the uterine cases reported by Mr. Morris evidently were; nor did I ever suggest or imagine that Chian turpentine would build up a new uterus, or repair a cancerous fistula of the intestines, or patch up a great cavity into the bladder, or restore a large recto-vaginal fistula with the fundus of the uterus extensively destroyed. Yet several of the cases described by Mr. Morris were of this character; and in these and in other cases of the same extreme gravity the remedy might well be deemed useless. I venture to suggest that in order to give the remedy a "prolonged and careful trial" it should not have been employed in such cases as those just described from Mr. Morris's report, but that three or four cases of uterine cancer should have been selected in which the destructive agency of the disease had not involved any other vital organs, and in which in all probability an extended trial of the remedy could have been secured.

Referring to my own experience—and it is abundantly confirmed by the published statements of other practitioners, as well as by numerous private communications in my possession—Chian turpentine, in cancer of the uterus, does relieve pain in the majority of instances; hæmorrhage is arrested; in some cases there is a marked diminution of the cancerous mass; and in others there is an apparent entire disappearance of it, as well as a marked improvement of the general health. In nearly all the cases which I have had under treatment for some time there has been a notable absence of glandular and secondary complications. Two of the cases, originally reported in THE LANCET, which came under treatment respectively fourteen and thirteenth months ago, are known to be still living, and in them there is no sign of a return of the disease, although one of the patients suffers from a difficulty in defecation from a stricture of the rectum; and a large number of cases have been under treatment at the Queen's Hospital during the past eight months which fully justify the previous observations as to the relief from hæmorrhage, &c., by the administration of Chian turpentine. These results have been so uniform and constant that I cannot understand Mr. Morris saying that "I am not able to report that there is a single symptom over which the drug seems to exercise even frequently, not to say constantly, an influence. It cannot be relied upon to assuage pain, to diminish or alter the character of the discharges, to check hæmorrhage, or promote the destruction of the growth by ulceration or sloughing." Relief has been afforded in cases of cancer in other parts of the body under observation, but then Mr. Morris would attribute this to a temporary arrest of the disease, of the possibility of which I have not been able to thoroughly satisfy myself.

I think I am justified in coming to the conclusion that Chian turpentine is far from being "useless" in the treatment of cancer, and that as no other drug administered internally has hitherto been equally efficacious in relieving pain, arresting hæmorrhage, and causing the disappearance of the growth—thus showing that it does "touch" the disease—it is the duty of the profession to ascertain and determine its properties thoroughly by beginning the treatment early, and continuing it patiently, and to record the results; for I am fully convinced—leaving the ultimate results out of the question, as time can alone determine them—that, if only for affording relief, the Chian turpentine is of inestimable value in the treatment of many cases of cancer.

No apology is necessary for treating this question in a general way; consideration for your space, and the fact that I intend shortly to bring the results of my experience before the profession, make it needless for me now to enter into details.

I append the following extract from a communication to the November number of the *Medical Brief*, an American journal, from Dr. A. V. Banes, who has employed the

Chian turpentine in seven cases of cancer of the generative organs. Dr. Banes writes:—"I have been waiting for some abler pen than mine to start the ball rolling and proclaim to the medical world that even if we have not a specific for that dread disease, we have at least an agent that palliates symptoms and affords relief to the victim, which had never been secured before the remedy was exhibited."

I am, Sir, yours obediently,
Birmingham, Dec. 7th, 1880. JOHN CLAY.

TREATMENT OF PHTHISIS.

To the Editor of THE LANCET.

SIR,—Dr. G. H. Mackenzie's interesting letter in THE LANCET of November 27th seems to me to give very valuable hints for the treatment of phthisis. Tar, or its derivatives, have been found useful not only in phthisis, but also in bronchitis, by Sidney Ringer and others. I myself have used creasote inhalation a good deal in phthisis, and tar internally in chronic bronchitis and chronic phthisis, and, I believe, with benefit. I have no doubt Dr. Mackenzie's inhaler will be found to be an important addition to our therapeutic resources, though a very similar appliance has been invented by Dr. William Roberts of Manchester.

I must, however, object to the statement "that it is generally accepted that phthisis is a parasitic disease." I think there are still some who believe, with Niemeyer, Virchow, and others, that phthisis, in many, if not most, cases, is the result of catarrhal pneumonia following upon an ordinary bronchial catarrh, and who do not think it necessary that the catarrhal discharge should form a nidus for a parasite.

If we admit that in catarrhal pneumonia there is a rapid production of cells which take on a particular character, why should we not go a little further, and infer that these cells, when discharged from the body, may retain a certain amount of vitality sufficient to cause them to take root in a healthy lung, and reproduce their kind? Such a process would be similar to that seen every day in skin-grafting, only that in the latter case the cells are in their normal condition. I am inclined to doubt that caseation is any more rapidly fatal to vitality and reproductive power on the one set of cells than the natural development and induration of cell-wall are in the other. That cells in an abnormal condition can reproduce themselves very rapidly is seen in cancer, &c.

I, for one, think that the introduction of the parasites into the theory of causation of phthisis is quite unnecessary. I also think that there is a danger of being misled in our treatment by such a theory. Processes of a septic or quasi-septic nature, no doubt, enter largely into the clinical history of phthisis, and antiseptics are useful; but I think we should be careful not to have our eyes blinded to even more important indications.

I, who am myself a Scotch Highlander, can assure you that there are many other changes in the social condition of my countrymen besides the absence of peat-smoke that affect their tendency to phthisis.

I am, Sir, yours respectfully,
DUNCAN J. MACKENZIE, M.D.
Glossop, Derbyshire, Nov. 30th, 1880.

ALL SAINTS CONVALESCENT HOSPITAL AND THE HOSPITAL SUNDAY FUND.

To the Editor of THE LANCET.

SIR,—Kindly allow me to inform all who are interested in this hospital that we have been compelled to return the grant lately made us by the Hospital Sunday Fund, on the ground that the conditions imposed upon its acceptance are such as to preclude the possibility of our availing ourselves of it. We have arrived at this conclusion after much lengthy and earnest consideration, and not without the co-operation and counsel of very influential friends, well able to assist us by their advice.

The "conditions" I refer to are that we give to the Hospital Sunday Fund 250 "letters" in return for the 500 guineas. The grant would thereby be reduced in value to 250 guineas, or, at the rate of thirty shillings, which is paid

by each patient not having a subscriber's "letter" and which is hardly sufficient to defray the cost of a patient for three weeks, to £150.

First, by such an act we should be contravening two of our rules, and be dealing unfairly towards our numerous subscribers. Secondly, the issue of 250 "letters," in such a wholesale way, would involve a demand upon the hospital accommodation with which it would be unable to cope, even with its present dimensions. Thirdly, this stipulation was not laid before us when making the application, or it certainly would not have been made. These are some of our reasons for thus acting.

We are preparing, as speedily as possible, for the enlargement of the hospital in two of its departments, which will increase the number of our beds to over 300, and this additional accommodation is necessitated by the present applications for relief, many of which we are compelled to refuse, simply for want of room.

A free gift of £500 to our funds would be a most invaluable help at any time, especially just now, but if all our subscribers and donors were to impose the terms of the Hospital Sunday Fund, this institution would have to be immeasurably enlarged, while the question of maintaining its efficiency would become a very serious problem.

I am, Sir, yours faithfully,

EDMUND IBBOTSON, Chaplain.

Eastbourne, Dec. 6th, 1880.

* * It is quite intelligible that the Eastbourne Convalescent Hospital should object to give so large a number of letters for the grant awarded to it by the Hospital Sunday Fund. But it is greatly to be regretted that the authorities of this hospital did not acquaint themselves with the conditions of the grant before asking for an award. The Fund cannot be expected to give a grant unconditionally to any hospital, and certainly not to the Eastbourne Convalescent Hospital. The rule of the Fund on this subject has been generally accepted, we believe, by other Convalescent Homes, and the Council should not make any special exception in favour of this hospital without grave consideration. It looks as though this hospital could not bear the restrictions of an ordinary public institution.—ED. L.

PARIS.

(From our own Correspondent.)

PROFESSOR BROWN-SÉQUARD resumed his lectures on Medicine at the Collège de France on the 7th inst., taking as his subject the Dynamic and other changes arising in the Animal Organism from Distant Irritation. The Professor was received with a hearty welcome from a select but sympathetic audience. The lectures will be continued on the Tuesday and Thursday of each week.

At the Society of Surgery a paper was read a few weeks since by M. Verneuil, on the Impropriety of Medical Treatment of Cancer of the Tongue. The only remedy which can give a good result is thorough extirpation of the diseased structure, which can but be aggravated by topical applications or general treatment. Other members of the Society were unanimous in subscribing to the same views.

An interesting discussion is expected next Friday at the Société Médicale des Hôpitaux, when Dr. Debove will give details of a case of, and read a paper on, Sciatic Nerve-stretching for Locomotor Ataxia. A report of the meeting will be found in a subsequent number of the *Gazette Hebdomadaire*.

A decision of some interest to the medical profession, and still more so to dispensing chemists, was given last week by the Tribunal Correctionnel of Paris, in a case of accidental poisoning. A prescription for a certain quantity of hydrobromate of quinine was given by a physician to one of his patients, a *conciérge*. The chemist to whom it was taken to be dispensed weighed out the drug from a bottle labeled "quinine," but which turned out to contain sulphate of morphia. In consequence of the mistake the patient lost his life, and legal proceedings were instituted by his widow against the *pharmacien*, who endeavoured to shift the responsibility upon the wholesale druggists with whom he dealt. The Court, considering both equally culpable, sentenced each to a week's

imprisonment and to a fine of 600 francs, and at the same time awarded as damages the sum of 4000 francs and an annuity of 900 francs a year.

The same tribunal has had also to deal with a case which has excited great indignation both in and out of the profession. A young man suffering from typhoid fever with symptoms of mild delirium was taken to the Hôpital St. Antoine. He there fell into the hands of a brutal and irritable *infirmier*, who, disturbed by the patient's agitation, applied a strait-jacket to keep him quiet. According to the evidence of the other patients the circumstances of the case were peculiarly atrocious. After tying the unfortunate young man hand and foot, the attendant appears to have used the utmost violence to his victim, whom he finally left almost inanimate on the bed, remarking as he went away from the scene of action, "Il est cuit"—literally, "He is cooked." The patient died the following day, and Dr. Dujardin-Beaumetz considered that, if not due to the ill-usage, his death had at any rate been accelerated by it. In defence it was maintained that the hospital attendants were in the habit of applying the strait-jacket at discretion in the interest of the other patients, and, strange to say, the director of the institution endorsed this statement. A year's imprisonment was the decision of the judge, and considering the inadequacy of the sentences which are always passed in France for the punishment of homicide, the offender may be said to have got his merits.

The *Gazette Hebdomadaire* in its *feuilleton* of the 3rd of December relates a case of ovariectomy, where the operator met with three ovaries. All three were extirpated, and the patient recovered.

The first number of a new review, the *Archives d'Ophthalmologie*, has just appeared. It is published by Professor Panas with Drs. Landolt and Poncet, and will certainly become the leading journal on that subject in Paris.

It is also rumoured that another serial publication is forthcoming on Mental and Nervous Medicine. It will be directed by Professor Ball and Dr. Luys, and will borrow its title from an English contemporary *Brain*, figuring in French as *L'Encéphale*.

Paris, Dec. 7th, 1880.

SKETCHES IN CONTINENTAL HOSPITALS.

(By our Special Correspondent.)

LYONS.

LYONS, the second city of France, is well supplied with hospitals, and they are all in active operation. The larger consist of the Hôtel Dieu, with 1061 beds; the Hospice de la Charité, with 1217 beds; the Hospice des Incurables, with 205 beds; the Hospice Antiquaille, with 1893 beds.

The Hôtel Dieu dates from the sixth century, having been founded by King Chilbert and Queen Ultrogotha, statues of whom decorate the façade of the hospital. The present building, which is of great size, and is built in the classical style, was begun in 1737, and finished in 1842. It faces the broad and rushing river Rhone, and presents an imposing stone front of great length. Squares separate the various blocks of wards from each other, and in these squares both flowers and shrubs grow and flourish. In one of them is a monument to M. Bonnet, the former distinguished surgeon of Lyons, and in another there is a statue of Eliza Lee, the Narcissa of our poet Young.

The hospital comprises 929 free beds (*gratuits*), 130 beds for patients paying two francs each per diem, and two special wards to accommodate patients who are able to pay twenty francs a day. To attend to the sick there are eight physicians, with six assistants (*suppléants*), one surgeon-major, one aide major, and one major titulaire; besides these principal officers there are 42 pupil house-surgeons, 200 *sœurs de charité*, and 50 *frères de charité* (Anglican hospitalers or nurses). Children are not supposed to be admitted, although this rule is not strictly adhered to; patients with mental diseases, including epilepsy, are also excluded, and skin diseases and syphilis are treated at the Antiquaille Hospital.

One of the best known officers of the Hôtel Dieu is M. Ollier, whose subperiosteal resections have made his name famous throughout Europe. He is an admirable clinical

teacher, and is listened to with marked attention by a large class of students, to whom his instruction is given in a most courteous and winning manner. His hospital visit occupies from 8.30 to 11.30 A.M., and during that time he operates as well as teaches at the bedside. His wards seemed crowded, some of the male wards having as many as 42 beds, while those for females were less crowded, averaging from 20 to 25 beds. I propose to give a short account of some of the more interesting operative cases I saw under M. Ollier's care at the time of my visit:—

CASE 1. Resection of shoulder-joint.—Done six weeks previously; the wounds were united and the movement considerable. One incision had been made along the front of the deltoid, and another, smaller and shorter, inwards along the outer end of the clavicle. M. Ollier always preserves the periosteum in this as in all other resections. In the Museum are numerous specimens showing his experiments upon rabbits, to illustrate the power of the periosteum in reproducing bone. Probably the good results obtained were due, as Goodsir pointed out ("Anatomical and Pathological Observations," 1845), to the adherence of some osseous granules to the periosteum; but there is no doubt about the fact of M. Ollier having given great attention to this subject, and of his having by his writings established this as a new department of conservative surgery.

CASE 2. Strumous disease of the head of the humerus in a boy, which had been treated advantageously by the application of the thermo-cautère to the interior of the carious cavity, and by free drainage right through the bone.

CASES 3 and 4. Resection of elbow-joint.—One was a man of middle age, for whom the operation had been done the previous day, and in whom there had been secondary hæmorrhage, consequent upon the use of Esmarch's bandage. M. Ollier makes a bayonet-shaped incision, and dresses the wound antiseptically.

The second case had been done two months previously, and there was free movement at the elbow, with a very useful arm.

Lister's dressing is in general use, and since its introduction M. Ollier avers that erysipelas and septicæmia have disappeared.

His method of applying the dressing differs slightly from that of Lister. The carbolic spray is used, many drainage-tubes of various sizes, both large and small, being introduced instead of one or two main tubes; then he applies six layers of dry carbolised gauze, and over them the protective, which is cut larger than the gauze, so that it covers every part of it, and keeps in all discharge. He then fixes the whole with gauze bandages. The excision of the elbow done two months ago had had the arm slung to the head of the bed in a semi-flexed position by a pulley, and to this slinging M. Ollier attributed the free mobility which had resulted.

CASE 5. Genu valgum.—This condition had been treated by simply fracturing the lower end of the femur by bending the thigh forcibly across the edge of a table. Is not Ogston's plan or McEwen's better than this? I inquired; but M. Ollier said he had achieved some very good results by his plan of treatment.

CASE 6. Resection of ankle in a man for compound fracture of the lower ends of the tibia and fibula, done a month ago, with antiseptic precautions; an inch and a quarter of the bones had been taken away by two lateral incisions; there had been no constitutional excitement, but there was not much evidence of bony consolidation.

CASES 7, 8, 9. Excision of the wrist.—In these cases a single long incision had been made from the base of the first finger to a point midway between the lower ends of the radius and ulna, and a second short incision on the ulnar side of the hand, chiefly for drainage purposes, the carpal bones having been all extracted through the larger wound. In each of the three cases motion of the fingers had been begun early, and all were after the lapse of some weeks showing signs of recovery with useful hands.

CASE 10.—*Syme's amputation of foot*, in a boy, done twenty-four days ago, with an excellent result, the periosteum over the os calcis having been left. This modification has been practised by M. Ollier for the last sixteen years with good results, a sort of false joint forming which enables the patient to move the stump slightly. He prefers Syme's operation to Pirogoff's, only adopting the latter in traumatic cases.

I have occupied so much space in the description of the surgery of the bones and joints, that being M. Ollier's

specialty, that I must not attempt to detail any other of the lines of practice which he has introduced. I will therefore content myself with calling attention to his method of treating bronchocele, which is both novel and efficacious. He dissects off carefully all the coverings of the tumour, and then applies to its surface an oval piece of Canquoin's paste, a quarter of an inch thick, and just the size of the exposed part of the tumour; after the paste has been on four hours, it is removed, and the tumour dries up and shrivels away, without constitutional disturbance or pain, the cure being effected in from three to four months.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At an ordinary meeting of the Council, held on Thursday last, the minutes of the preceding meeting (held on the 11th ultimo) were confirmed. It was proposed that the portion of the minutes relating to Sir James Paget's motion (see THE LANCET, Nov. 20th, p. 822) be not confirmed, but, after some discussion and a division, the minutes were confirmed. Accordingly, Sir James Paget's motion was carried, and a committee was appointed to consider the resolution and the regulations relating to the several preliminary examinations recognised by the College, whether for the Membership or Fellowship, and to report thereon to the Council.

On the recommendation of the Committee on Examinations in Anatomy and Physiology, the following Fellows were elected members of the Board of Examiners in Anatomy and Physiology:—For Anatomy: Messrs. A. E. Durham, Walter Rivington, John Langton, T. P. Pick, and Edward Bellamy. For Physiology: Messrs. W. Morrant Baker, B. T. Lowne, J. McCarthy, and F. Gerald Yeo. There were ten other candidates. Mr. Butlin and Mr. Frederick Treves were appointed Erasmus Wilson Professors for the ensuing year, the former to deliver two lectures on the Structure and Nature of certain Tumours; and the latter one lecture on the Pathology of Scrofula. A letter from Dr. Haldane, a member of the General Medical Council, suggesting the institution of a compulsory preliminary scientific examination, was referred to the Committee on Preliminary Examinations. Mr. Holden's motion that the Annual Report of the President on the affairs of the College be discontinued was carried, with the following modification and addition:—"That an abstract of the proceedings of the Council and of any documents presented to the Council relating to matters not otherwise contained in the Calendar be prepared by the Secretary; and, subject to the approval of the President, be published annually in the Calendar of the College; and that the abstract be headed 'Secretary's Report.'"

Obituary.

ROBERT CEELY, F.R.C.S.

ROBERT CEELY has gone to the grave full of years, but far fuller of the honour which the personal regard of his profession and the affection of the people among whom he lived have attached to him. He was a noble illustration, happily not by any means a solitary one, of what the *general practitioner* of medicine may be, can be, and ought to be. No field of life, not even excepting the clergyman's, offers such opportunities for the development of all that is best in man as that of the general practitioner of medicine. He has his cares, his anxieties, his responsibilities as other men, and it may be that some of these responsibilities are of a nature which tell more severely upon the mind than upon the body. But he has opportunities for the scientific and practical study of his profession which fall to his lot almost alone among his brethren if he care to cultivate them; and above all, he alone has the opportunity of exercising his profession under such circumstances as tend to develop to the fullest extent the holiest aspects of humanity in its relation with his fellow-men and the highest gifts of charity. Of all this Robert Ceely was a grand illustration; and we hope the biographer will be forthcoming who will set forth in details the events of his life for the instruction of the younger

members of the profession, who have their lives before them, and who may gather from his example how large the opening for a great, good, nay, famous life exists in what is coxcomically held to be the *lower* ranks of the profession (Heaven save the mark!). Here, within the limits at our command, it is possible to glance only at the leading features of Robert Ceely's life.

He had already been several years in the practice of his profession at Aylesbury (having been diverted there from a project and hope of entering the East India Company's service) when the great outbreak of cholera of 1832 occurred. Aylesbury suffered in this outbreak, and Mr. Ceely displayed qualities of head and heart in contending with the disease that left a mark among the community ever after, and endeared him to rich and poor. It is reported that Lord Hardinge, the then Commander-in-Chief, in admiration of his conduct at that time gave Mr. Ceely's nephew a commission in the 42nd regiment. The year after the outbreak of cholera Mr. Ceely interested himself in the establishment of the Bucks General Infirmary, which has proved so inestimable a boon to the county, and to which he continued attached to the end of his life. Soon after he began those series of researches on vaccinia and variola with which his name will be imperishably attached, and respecting the author of which Mr. John Simon said he "has done more to advance the natural history of vaccination than any other individual since the days of Jenner"; and at a later date Dr. Seaton said, "The natural history of vaccinia in the cow has been studied more or less by various observers, but by none so accurately or so comprehensively as by our distinguished countryman Robert Ceely." His interest in this subject was maintained, and the accuracy of his judgment in regard to it appreciated, to the last day of his life. Many will remember his venerable presence at the medical conferences on "Animal Vaccination" a short time ago, and just before his death his advice was sought by and freely given to the Government in respect to cases of suspected natural cow-pock in Essex. There, in his eighty-third year, he was to be seen bringing his unequalled experience and skill to the assistance of the public in an Essex byre.

In 1865 he was associated with Earl Spencer, Mr. Robt. Lowe (now Lord Sherbrooke), Dr. Lyon Playfair, Dr. Parkes, Dr. Quain, and others in the Royal Commission on the Cattle Plague.

The principal works he published were as follows:—"Observations on the Variolæ Vaccinæ, with an Account of some Recent Experiments" (1840); "Further Observations on the Variolæ Vaccinæ" (1842); "Account of Contagious Epidemic Puerperal Fever" (1835). He also contributed articles to the *Med. Times and Gazette* "On the Vaccine and Equine Diseases" (1841); "Case of Malignant Fungoid Disease of the Tongue" (1847).

He was surgeon to the Bucks General Infirmary and County Gaol, and a member of both the Epidemiological Society and of the British Medical Association, at the last meeting of which, at Cambridge, he was present, and exhibited and described many of his exquisite drawings relative to vaccinia and variola.

Such, briefly, is an indication of the work he did from the scientific side of his character—work which will never be forgotten. But who will tell the history of his relations with the people among whom he lived for the threescore years of his active and useful medical life? Let the crowd at the grave, and their emotion as the coffin was placed there, and the flowers which covered it, suggest this phase of his existence—a phase, perhaps, which no pen can ever trace, but which, passed, has left an irreparable gap in the life at Aylesbury. The simple inscription on the coffin-plate will best end this notice:—Robert Ceely, died Sunday, November 28th, 1880, aged 83 years.

Medical News.

UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent B.S. Examination for Honours:—

SURGERY.

FIRST CLASS.

{ Day, Donald Douglas (Gold Medal), St. Barthol. Hospital.
{ Money, Angel (Gold Medal), University College.

SECOND CLASS.

Sheppard, Charles Edward, St. Thomas's Hospital.
Pollard, Bilton, University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following members having passed the Final Examination for the Fellowship on Nov. 25th, 26th, 27th, and 29th, were, at a meeting of the Council duly admitted Fellows of the College:—

Black, James, M.B. Cantab, Aytoun-road, Stockwell; Membership dated Jan. 1875.
Clippington Samuel Dodd, M.C. & M.D. Aberd., Church-street, Kensington; July, 1875.
Dunn, Hugh Percy, Guildford-street, Russell-square; Jan. 1876.
Greenish, Robert Wm., L.R.C.P. Lond., New-street, Dorset-square; July, 1875.
Lammiman, Cleland, L.R.C.P. Lond., Mount Ephraim, Tunbridge Wells; July, 1875.
Lloyd, George Jordan, L.S.A., Coventry-road, Birmingham; July, 1878.
MacDonnell, Jas. O'Malley, M.D. Queen's Univ. Irel., H. M. Indian Army; Nov. 1880.
Miles, Walter Jennings, L.R.C.P.L., Wynham-place, Bryanston-square; July, 1877.
Newby, Chas. Henry, L.R.C.P. Lond., Adelaide-road, Regent's-park; July, 1873.
Turner, Geo. Robertson, L.R.C.P.L., Sussex-gardens, Hyde-park; July, 1877.
Weiss, Hubert Foveaux, L.R.C.P. Lond., Church-row, Fulham; Jan. 1876.
Whitehead, Hayward Reader, L.R.C.P. Ed., Cadogan-ter.; Nov. 1877.
Young, Alfred Harry, M.B. Ed., Sankey-street, Warrington. (Not a member.)

Of the 25 candidates examined on the above-mentioned days, 12 failed to reach the required standard, and were referred for one year further professional study.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Dec. 2nd:—

Cooper, Richard Gilpin, Park-road, Southport.
Everard, Horace Nathaniel, Leicester.
Field, Cornelius, Fortress-road, Kentish-town.
Jerome, John William, St. Heliers, Jersey.
Orton, Arthur, Queen's College, Birmingham.
Osborne, Harold Rochester, St. Ives, Huntingdon.
Unsworth, Francis Henry, Derby.
Willis, Arthur, Soham, Cambridgeshire.

The following gentlemen also on the same day passed their Primary Professional Examination:—

William B. Baker and John Holroyde, London Hospital; H. William Campbell, Guy's Hospital; David William Jones, University College; Montagu Williams, Middlesex Hospital.

THE PARKES MUSEUM OF HYGIENE.—The Executive Committee of this Museum have, in response to a suggestion made by the Nineteenth Century Building Society, arranged for a course of lectures in the museum to the members of Building Societies. The subject of the lectures is to be "Dwelling-houses," and the first lecture of the course will be given next Saturday by Mr. Edward C. Robins, F.S.A., on "Situation and Construction." Free tickets for the lectures are being distributed by the several Metropolitan Building Societies. Captain Douglas Galton, C.B., F.R.S.; Mr. Robert Rawlinson, C.B., of the Local Government Board; and Mr. E. C. Robins, F.S.A., have just been elected members of the Museum Committee.

INSTRUCTION IN NURSING.—The first class of soldiers' wives for instruction in nursing under Lady Strangford's scheme, which has been approved by the Duke of Cambridge and by the Secretary of State for War, met yesterday at Woolwich, at 29, The Common, Lady Strangford superintending. The instruction was given by Mr. H. Crookshank, F.R.C.S., one of the lecturers for the St. John Ambulance Association, and author of a work on "Nursing and Hygiene." Great interest was shown by the pupils.

THE following are the disbursements of the different coroners of the Middlesex sessions, as presented on Wednesday:—Mr. Humphreys, for 175 inquisitions, from Oct. 1st to Nov. 10th, £307 2s. 8d.; Dr. Hardwicke, for 156 inquisitions, from Oct. 1st to Nov. 9th, £318 9s. 6d.; Dr. Diplock, 69 inquisitions, from Oct. 1st to Nov. 10th, £127 18s.; Mr. Bedford, 30 inquisitions, from Oct. 1st to the 29th, £65 18s.

GUY'S HOSPITAL REFORM.—We are informed that the Committee (chiefly of Vestrymen and Guardians of Southwark) formed for the purpose of dealing with this subject will meet to-day (Friday); and that a public meeting will be convened at eight o'clock on Wednesday evening, 15th December, at the Bridge House Hotel, Southwark, Arthur Cohen, Esq., M.P., Q.C., in the chair.

THE Bread Reform Association, with the permission of the Lord Mayor, is about to hold a Conference at the Mansion House.

ROYAL MEDICAL SOCIETY, EDINBURGH.—At a meeting of the above Society, held on the 26th ult., the following gentlemen were elected Presidents for the ensuing year:—W. Henry Dobie, M.B., C.M.; R. A. Lundie, M.A., B.Sc., M.B., C.M.; A. H. Barbour, M.A., B.Sc., B.M., C.M.; and A. L. Macleish, M.A.

THE managers of the Charing-cross Hospital, St. George's Hospital, St. Thomas's Hospital, and the Dreadnought Hospital, Greenwich, have received from the Prince of Wales and the Duke of Edinburgh presents of game for the use of the patients in the respective charities.

THE medical officer of the Bow Infirmary has received a gratuity of £50 from the City of London Union, the sum he had expended in preparing his defence in the case of the murder of Alfred Harris.

THE amount of the Hospital Saturday Collection at Wolverhampton, on the 4th inst., so far as is yet ascertained, is £900; but it is expected that when the accounts are complete, the sum realised will be at least double.

MR. T. COLLINGWOOD, M.R.C.S. Eng., late Medical Officer for the Wardleworth District and Workhouse of the Rochdale Union, has received a superannuation allowance of £75 a year.

VACCINATION GRANT.—Dr. Lionel A. Weatherly has been awarded a Government grant for efficient vaccination in No. 6 District, Bedminster Union (second time).

SIR GEORGE B. OWENS, M.D., J.P., has been appointed High Sheriff of the County of the City of Dublin for 1881.

A NEW chapel, affording accommodation for 200 persons, has just been opened in connexion with the Clewer Convalescent Hospital.

LAST week a concert was given at the Royal London Ophthalmic Hospital, Moorfields, for the entertainment of the inmates of the institution.

MR. W. H. BENNETT, F.R.C.S.E., has been elected a member of the Royal Institution.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ANDERSON, J. W., M.B., C.M., has been appointed Resident House-Physician to the Royal Infirmary, Edinburgh.

BALFOUR, J. C., L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Resident House-Physician to the Royal Infirmary, Edinburgh.

CAMPBELL, J. P., M.B., C.M., has been appointed Resident House-Surgeon to the Royal Infirmary, Edinburgh.

CROSSLEY, C. R., M.R.C.S.E., L.S.A.L., has been appointed a Medical Officer to the Leicester Provident Dispensary.

FLINN, D. E., L.K.Q.C.P.I., L.R.C.S.I., L.M., has been reappointed Medical Officer of Health to the Brownhills Urban Sanitary Authority.

GODFREY, A. C., L.R.C.P. Ed., L.R.C.S. Ed., has been appointed a Surgeon to the Southampton Dispensary and Humane Society.

GOLDING, J. P., M.D., L.M.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer to the Munster Lodge of Odd Fellows, vice Cremen, resigned.

GREASLEY, J., L.R.C.P. Ed., L.R.C.S. Ed., M.R.C.S.E., has been appointed Medical Officer for the Knighton District, in connexion with the Leicester Provident Dispensary.

HARDIE, R., M.B., C.M., has been appointed Resident House-Surgeon to the Royal Infirmary, Edinburgh.

HARGITT, H., M.D., L.R.C.S. Ed., has been appointed Medical Officer for the Humberstone District, in connexion with the Leicester Provident Dispensary.

HARRISON, E., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Hordley District of the Ellesmere Union.

HORNE, J. F., F.R.C.S. Ed., L.F.P.S.G., L.S.A.L., has been appointed Honorary Surgeon to the Beckett Hospital and Dispensary, Barnsley, vice Stanman, deceased.

JARDINE, A. M.B., C.M., has been appointed Assistant Medical Officer to Longmore Hospital, Edinburgh.

JONES, Mr. A. E., has been appointed a House-Physician at the London Hospital, vice Hardy, resigned.

LOGAN, J. R., M.B., C.M., has been appointed Resident House-Physician to the Royal Infirmary, Edinburgh.

LUNDIE, R. A., M.B., C.M., has been appointed Resident House-Physician to the Royal Infirmary, Edinburgh.

MOORE, C. A., M.B., M.R.C.S.E., L.S.A.L., has been appointed a Medical Officer to the Leicester Provident Dispensary.

MORTON, S., M.B., M.R.C.S.E., has been appointed Surgeon to the W Division of Metropolitan Police at Croydon, and Examiner of Recruits for the Militia and Regular Army in the Croydon District.

O'REILLY, J., M.B., C.M., has been appointed Resident House-Physician to the Royal Infirmary, Edinburgh.

OSWALD, H. R., M.B., C.M., has been appointed Medical Officer at the Royal South London Dispensary.

PALK, H., M.D., M.R.C.S.E., L.S.A.L., has been appointed a Surgeon to the Southampton Dispensary and Humane Society.

PARKINSON, C. H. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Wimborne and Cranbourne Sanitary District, Dorsetshire.

PARRY, R., M.R.C.S.E., L.S.A.L., has been appointed Assistant Medical Officer and Dispenser to the Central London Sick Asylum, Cleveland-street, vice Hewett, resigned.

POTTS, L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Leatherhead and Fetcham District of the Epsom Union, vice Owen.

ROBIE, H. W., M.B., C.M., has been appointed Resident House-Surgeon to the Royal Infirmary, Edinburgh.

ROSE, J. M., M.B., C.M., has been appointed Resident House-Surgeon to the Royal Infirmary, Edinburgh.

ROWLAND, J., M.D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Lower District of the Tregaron Union, vice R. Rowland, resigned. £35 per annum.

SCOTCHBURN, A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for Great Driffield Urban Sanitary District.

SMYTH, S. J., L.R.C.P. L., F.R.C.S.E., has been appointed Consulting Surgeon to the Infirmary for Sick Children, Sydenham-park, upon resigning as Honorary Surgeon.

SNOAD, E. H., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Aylestone District, in connexion with the Leicester Provident Dispensary.

TOWNSHEND, C. B., M.D., L.K.Q.C.P.I. & L.M., L.R.C.S.I., has been appointed a Surgeon to the Southampton Dispensary and Humane Society.

TURNER, R., M.B., C.M., has been appointed Resident House-Physician to the Royal Infirmary, Edinburgh.

WADE, A. B., M.B., C.M., M.R.C.S.E., L.S.A.L., has been appointed a Surgeon to the Southampton Dispensary and Humane Society.

WATERS, J. L., M.B., C.M., has been appointed Resident House-Surgeon to the Royal Infirmary, Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

BROWNE.—On the 2nd inst., at the Royal Naval Hospital, Great Yarmouth, the wife of Dr. Thomas Browne, of a daughter.

COCKELL.—On the 5th inst., at Forest-road, Dalston, the wife of Frederick E. Cockell, jun., M.R.C.S.E., of a son.

GAIRDNER.—On the 28th ult., at Bridge-street, Stratford-on-Avon, the wife of John Gairdner, M.R.C.S.E., L.S.A.L., prematurely, of a son (stillborn).

GROSVENOR.—On the 2nd inst., at Ladbroke-grove, Kensington-park, Notting-hill, the wife of George Fox Grosvenor, M.D., of a son.

MAY.—On the 26th ult., at Moreton-Hampstead, South Devon, the wife of Albert E. May, L.R.C.P.L., of a daughter.

PHILIPPS.—On the 1st inst., the wife of Alfred Philipps, M.R.C.S.E., of Maitland-park, of a son.

MARRIAGES.

BAIRD.—WINTER-WOOD.—On the 1st inst., at St. George's, Hanover-square, William James Baird, M.D., Fleet-Surgeon, R.N., to Edith Elina Helen, daughter of T. Winter-Wood, Esq., of Mariestead, Netley Abbey, Hants.

COX.—CROWLE.—On the 7th inst., at St. Mary Abbott's Church, Kensington, by the Vicar, Frederick Augustus Cox, M.R.C.S.E., of Dean-street, Park-lane, to Elizabeth Patience (Bessie), only daughter of the late T. R. Crowle, of Kensington. No cards.

FISHER.—TABOR.—On the 2nd inst., at Christ Church, Streatham, Frederick Bazley Fisher, M.R.C.S.E., L.R.C.P.L., of Dorchester, fourth son of Stephen Fisher, of Tiverton, Devon, to Cecilia Metcalf, third daughter of the late William Tabor, of Rose Mount, Brentwood, Essex, and Mrs. William Tabor, of Heathfield Lodge, Queen's-road, Clapham-park.

KERR.—FIELD.—On the 9th inst., at St. John's Episcopal Church, Edinburgh, by the Rev. Canon Sandford, LL.D., Incumbent, Surgeon-Major Kerr, M.D., to Katharine Burch, younger daughter of the Rev. Edward Burch Field, of Moreland, Kinross-shire.

KIBBLER.—LEECH.—On the 4th inst., at St. John of Jerusalem, South Hackney, William Ambrose Kibbler, M.B., of Mordaunt House, Mare-street, Hackney, to Rosina, youngest daughter of the late William Leech, of Terrace Lodge, South Hackney.

MOXON.—TUCKWELL.—On the 1st inst., at South-street, Exeter, by the Rev. F. Bosworth, M.A., assisted by the Rev. J. Tuckwell (brother of the bride), Dr. William Moxon, of Matlock, Derbyshire, to Julia, youngest daughter of Henry Tuckwell, Esq., of St. Leonard-road, Exeter, Devon. No cards.

DEATHS.

GENET.—On the 4th inst., at Hollywood-road, Frederick James Genet, M.R.C.S. and L.S.A.L., in his 61st year.

JONES.—On the 29th ult., after a long illness, at his residence, Waterloo-place, Leamington, Richard Jones, F.R.C.S., in his 81st year, deeply lamented.

TAYLOR.—On the 2nd inst., at Holland-road, Kensington, Henry Taylor, M.D., H.M.'s Indian Army (retired), aged 78.

WEEKES.—On the 3rd inst., at Carey Hall, Hurstpierpoint, Sussex, George Weekes, F.R.C.S., Deputy-Lieutenant for the County, aged 63.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

Monday, Dec. 13.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL. — Operations, 1½ P.M. each day, and at the same hour.
 METROPOLITAN FREE HOSPITAL. — Operations, 2 P.M.
 ROYAL ORTHOPÆDIC HOSPITAL. — Operations, 2 P.M.
 ST. MARK'S HOSPITAL. — Operations, 2 P.M.: on Tuesday, 9 A.M.
 BROWN INSTITUTION (in the Theatre of the University of London). — 5½ P.M. Dr. W. S. Greenfield (Professor-Superintendent): "Further Investigations on Anthrax and Allied Diseases in Man and Animals."
 MEDICAL SOCIETY OF LONDON. — 8½ P.M. Dr. Allchin, "On a Case of Gastric Ulcer." — Dr. Habershon: "Notes of a Case of Obstruction of Colon from Contraction of Calibre of Intestine."

Tuesday, Dec. 14.

GUY'S HOSPITAL. — Operations, 1½ P.M., and on Friday at the same hour.
 WESTMINSTER HOSPITAL. — Operations, 2 P.M.
 WEST LONDON HOSPITAL. — Operations, 3 P.M.
 ROYAL MEDICAL AND CHIRURGICAL SOCIETY. — 8 P.M. Ballot. — 8½ P.M. Dr. Bantock, "On Hyperpyrexia after 'Listerian' Ovariectomy." — Mr. Lawson Tait, "On Hydatids of the Liver treated by Abdominal Section and Drainage." — Dr. Thin will show the subject of an unusual form of Skin Disease.
 ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND. — 8 P.M.

Wednesday, Dec. 15.

NATIONAL ORTHOPÆDIC HOSPITAL. — Operations, 10 A.M.
 MIDDLESEX HOSPITAL. — Operations, 1 P.M.
 ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.
 ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.
 ST. MARY'S HOSPITAL. — Operations, 1½ P.M.
 KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.
 LONDON HOSPITAL. — Operations, 2 P.M., and on Thursday and Saturday at the same hour.
 GREAT NORTHERN HOSPITAL. — Operations, 2 P.M.
 UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.
 BROWN INSTITUTION (in the Theatre of the University of London). — 5½ P.M. Dr. W. S. Greenfield (Professor-Superintendent): "Further Investigations on Anthrax and Allied Diseases in Man and Animals."
 ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY. — 7½ P.M. Council. — 8½ P.M. Mr. Edmund Owen, "On Maxillary Abscess and Necrosis in Childhood."
 SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE. — 8 P.M. Mr. E. Price Edwards, "On the Use of Sound for Signals."

Thursday, Dec. 16.

ST. GEORGE'S HOSPITAL. — Operations, 1 P.M.
 ST. BARTHOLOMEW'S HOSPITAL. — 1½ P.M. Surgical Consultations.
 CHARING-CROSS HOSPITAL. — Operations, 2 P.M.
 CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.
 HOSPITAL FOR WOMEN, SOHO-SQUARE. — Operations, 2 P.M.
 HARVEIAN SOCIETY. — 8½ P.M. Second Harveian Lecture, by Dr. J. E. Pollock, "On the Prognosis and Treatment of Chronic Diseases of the Chest in relation to Modern Pathology."

Friday, Dec. 17.

ST. GEORGE'S HOSPITAL. — Ophthalmic Operations, 1½ P.M.
 ST. THOMAS'S HOSPITAL. — Ophthalmic Operations, 2 P.M.
 ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M.
 BROWN INSTITUTION (in the Theatre of the University of London). — 5½ P.M. Dr. W. S. Greenfield (Professor-Superintendent): "Further Investigations on Anthrax and Allied Diseases in Man and Animals."

Saturday, Dec. 18.

ROYAL FREE HOSPITAL. — Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

SEAWEED AS A SUBSTITUTE FOR JAM.

AMONG the few serious political papers published in Paris, we note that the *Temps* occasionally renders good service by describing, in popular language, frauds that gravely compromise public health. Thus on the subject of jellies we have some startling disclosures. We should remark that in France fruit preserves are generally sold as jellies, and not as jam, in which the seed, stones, and sometimes the outline or skin of the fruit itself can be discerned. Falsification is, therefore, more easy. For this purpose gelatine made from fish naturally suggested itself, but was found too expensive. Of late years, however, since the importation on such a large scale of Chinese and Japanese porcelain, &c., a new solution has been found to the problem. The objects imported are generally packed with a common maritime plant that is used instead of straw. This seaweed possesses, however, peculiar properties. When placed in a tumbler of water, it absorbs the water in a few minutes; then a number of shoots grow, and constitute a jelly nearly as transparent as the water from which it is made. This plant, the *Arachnoidiscus japonicus*, only costs the trouble of bringing it over. The jelly it yields is easily sweetened with glucose, and cochineal or other colouring matter is added with equal facility to imitate the colour of the fruit. The perfume and the taste were the only real difficulties that remained to be overcome. After considerable study it was discovered that by mixing four parts of acetic ether and tartaric acid with four parts of glycerine and one part of aldehyde, formic ether, benzoic, butyric, amylic, acetic, cyanhydric, mythal-salicylic, nitrous, reberythric, and succinic, a perfect imitation of the odour of raspberries was produced. By putting a little of this essence to the seaweed which has been allowed to develop itself in water, a substance is obtained which has the consistence of fruit jelly, though no fruit has been used, which is sweet, though no sugar has been employed, and which has the colour and fragrance of raspberries, though altogether destitute of that fruit. When this ceases to please, another very good fruit flavour is produced by treating castor oil with nitric acid! Fortunately, though wonders are wrought with the *Arachnoidiscus japonicus*, the result is not absolutely perfect. The jelly still retains a little of the fibrous nature of the plant, and has a tendency to split and fall to pieces, instead of forming adhesive lumps. Examined with the microscope, it has no resemblance to the jelly made from fruit. Then, as the jelly must be coloured, it is easy enough to discover the presence of an artificial dye. Without resorting to the laboratory, it suffices to dissolve a little of the suspected jelly in some tepid water, and dip a white silk ribbon in the solution. If it is a natural jelly, the ribbon will simply be a little soiled; but if the jelly has been artificially coloured, the ribbon will also be coloured. By giving publicity to all these details, the frauds practised will be constantly discovered, and the perpetrators brought to justice. We fear also that the falsifications the French have contrived, the English will not be slow to imitate, unless it is generally known that the public are on the *qui vive*.

FEES TO INSURANCE AGENTS.

Mr. T. Cawley Eager. — We entirely agree with our correspondent, and will take some pains to represent the system to the directors in its true light.

W. X. Y. — Dr. George Wilson's "Handbook of Hygiene," published by Messrs. Churchill, will probably meet our correspondent's wishes.

M.D. — We believe not; but the question should be addressed to the Clerk of the Union or the Local Government Board.

A HARDSHIP IN THE POOR-LAW MEDICAL SERVICE.

Mr. Charles Cooper, (Needham Market).—The case submitted to us we have no hesitation in saying is against the spirit of the Poor Law, although it may appear to carry out the letter. We have some doubts whether the Local Government Board would regard it in this sense. We should strongly advise our correspondent to submit the correspondence to the Local Government Board. If he hesitate to do this, it should be possible in part, in his district, to protect himself from the hardship of which he complains of by insisting on some who are paupers, and expecting confinement, and who look for his attendance, applying for an order to the guardians two or three weeks before the time the confinement is due, as recommended by the Local Government Board.

THE NAVAL MEDICAL SERVICE.

A Tanner.—We do not think the publication of our correspondent's letter would in any way be advantageous to the department. On the contrary, it might possibly exert a prejudicial influence at a time when the question of modification of the service is under the consideration of the authorities. Other subjects of at least as much importance as increase of pay must be dealt with if the existing state of discontent is to be remedied.

SANITARY WORK.

To the Editor of THE LANCET.

SIR,—Just as a red flag waved before the eyes of the tortured and tired bull will always madden him for fresh exertion, so I think whenever the questions of milk, sanitary regulations, and medical etiquette as connected with the duties of medical officer of health are brought prominently before the medical world, as in the late case at Surbiton, a great many of us will feel inclined to growl out complaints, and that must be my excuse for breaking a lance in the following lengthy letter.

It is now some years since a great stir was made in the outside as well as in the medical world concerning the health of the nation, and how much it might be improved by arranging a more perfect code of sanitary laws, and appointing officers to see them enforced. Boards of health sprung up in every town, medical officers were appointed, inspectors of nuisances created, and additional salaries and additional duties given to surveyors. Has the result justified the expenditure? Much honest work has been done; many evils removed; good men have sacrificed their time, health, and lives in their very eagerness to discover the causes that give rise to the disease germs. The work is still going on; but is it fast enough, cannot more be done to rescue this thickly-populated land from the spread of the devastating zymotic diseases? I think it can, but not under the present regulations. Whilst medical men and their patients are allowed to cover up these diseases with the blanket of secrecy, zymotic diseases will flourish like and deadly in our midst. Amongst small communities, some small town I would say, especially where the medical men of the place are on friendly terms with the medical officer of health, many precautions can, and are, taken that it is hopeless to look for in large towns under the present regulations. Could anything be more ridiculous than the present regulations made to guard our homes from invasion by contagious and infectious diseases? For instance, let scarlet fever lie dead, or, better still, let it in imagination be entirely blotted out from amongst us in London for a few months, then reintroduce it in single cases in a few crowded districts. If such could be, are our sanitary laws stringent enough, are our medical officers of health numerically strong enough and sufficiently on the watch to grasp the nettle on its first appearance, and destroy it? With such a disease as the plague, &c. &c., when everyone is frightened, they would get every assistance from the populace; but with the common fevers of the land, familiarity, if it has not bred contempt, has at least made many careless; and whilst there is no regulation, no law that every case shall be reported, secrecy will do its work. Our sanitary authorities possess much power, and they use it wisely and well; but whilst they have to fight in the dark until they are able to grapple with the foe, "Secrecy," many of their best efforts will be defied and barren. Now, the knowledge of how fever frequently spreads amongst us is patent to all, and yet without raising a finger, without striking the smallest of blows in defence, we receive the enemy—in fact, run open-handed to him. We bully the builder, we worry the house-agent, we vex the landlord to get our drains &c. put into working order; we write long letters, and abuse the water we drink—in a word, we shut up three sides of our castle, but on the fourth we leave wide open the port; we throw wide open the gate without even placing a sentinel on guard; for do we not unhesitatingly buy at any shop whatsoever our tastes are pleased with and our purse will allow? and yet what a large proportion of goods exhibited are made by the working classes in their own homes—homes not unfrequently visited by some infectious and contagious disease at long or short intervals. As an example, I would cite one solitary case out of the many that come under my notice:—A woman, who earns a large sum weekly as a furrier, has two children down with scarlet fever; to give up work means little better than to be reduced to a state of pauperism. Then comes in the alternative; either the medical attendant must countenance a great wrong, or he must inform the medical officer of health, and get his authority, and so doing risk offending the patient, her friends, and perhaps a wider connexion, or he must be content with threatening, and risk the work being done in secrecy.

Your obedient servant,

CLEMENT E. PRIESTLEY.

St. Agnes-terrace, Victoria-park-road, Dec. 1880.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

The following were the questions on Anatomy and Physiology submitted to the twenty-two candidates at the half-yearly examination for the Fellowship of the College on the 19th ult., when three out of the four questions were required to be answered:—

1. Describe the veins of the head and neck, including those of the spine, but omitting those within the cranium.
2. Describe the convolutions and fissures seen on the outer surface of one hemisphere of the brain.
3. Describe the dissection necessary to expose the whole length of the thoracic duct. Give its course, relations, and tributaries.
4. Give the dissection required to display the parts concerned in inguinal hernia. Describe fully the inguinal canal and its contents in both sexes.

The following were the questions on Physiology:—

1. Describe the development of the internal ear in mammals.
2. Describe the microscopic appearance of the cells of the parotid and sublingual glands as seen in sections made from glands which have been at rest, and in sections from corresponding glands which have been subjected to prolonged excitation. What inferences may be drawn as to the action of such cells from these appearances, and by what experiments may these inferences be corroborated?
3. Give the structure of one of the large serous membranes, and describe its relations to the lymphatic system. State the modes in which lymphatics arise, and the forces by which the movement of the fluid in them is maintained.
4. Describe the extrinsic and intrinsic innervation of the heart.

The following were the questions on Pathology, Therapeutics, and Surgery at the written examination for the Fellowship on the 25th ult., when they were required to answer all four questions from 1.30 to 5.30 P.M.:—

1. Mention the several effects, immediate and remote, of severe contusions of the perineal region in the male.
2. In a case of popliteal aneurism, what methods of treatment would you consider? Describe fully the conditions by which you would be guided in the choice of any particular plan.
3. Discuss the pathology of erysipelas. State the evidence upon which your view of its nature is based.
4. Mention the several morbid products which may be found in the urine. How are these to be distinguished, and what diagnostic inferences may be deduced from their presence?

Enquirer—Iodoform, five grains; oil of eucalyptus globulus, ten minims; dissolved in cacao-butter, and cast in a bougie four inches long.

Dr. Prickett.—The paper is marked for insertion.

"THE CHLOROFORM DEATH-BILL FOR TWELVE MONTHS."

To the Editor of THE LANCET.

SIR,—Dr. Jacob's letter in your issue of Nov. 27th is an advance upon his paper. He tells us that chloroform is, "at the most, fatal once in 3000 cases." This is wonderful success if we consider how often it is given in defiance of the necessary precautions, and how often accidents and other circumstances render its use necessary without any preparation at all. This remark applies also to ether. What is the difference between the last two decades? From my point of view, a vastly more general use of anaesthetics and a vast increase in the number of trained administrators would render the comparative statistics of deaths merely somewhat unsatisfactory. There is also the question of the sample of chloroform. Fifteen years ago, as students, we were taught that chloroform was practically free from danger if properly administered. A few years since ether was reintroduced as absolutely free from danger; but the first death disproved this statement, and left the question of comparative safety to be settled. With limited opportunities I could not unaided reach a conclusion satisfactory to myself; but a small experience was adverse to ether. On making inquiries concerning the practice of my former teachers and others, in whose judgment I have every confidence, I was told that, without exception, they had gone back to chloroform. Although this does not accord with Dr. Jacob's statement, I do not doubt that he speaks fairly of his own experience and neighbourhood; but older men must be permitted to attach some value to a previous lengthy and satisfactory experience of chloroform.

Dr. Sandby's paper on Anaesthetics in your issue of Nov. 20th is very welcome as a temperate estimate, and suggests one question which seems to me important: How much both of the safety and danger of ether depends upon the large amount given? It is given in enormously larger quantity than chloroform, and therefore the limit of safety in dose is probably less easily overstepped. On the other hand, how much of its danger depends upon the effect on the respiratory tract of the large quantity required? If this be true, it ought to be an objection to its prolonged administration; but I put the question to elicit information.

I am, Sir, your obedient servant,

Guernsey, Nov. 1880.

J. AIKMAN.

A Combatant Officer.—We sympathise with our correspondent in his disappointment; but a careful inquiry has satisfied us that the detention was an unavoidable result of the state of matters in Afghanistan. We understand that steps are being taken to relieve officers whose time of service has expired with as little delay as possible consistently with the necessities of the service.

E. M. S.—We have no recollection of the article mentioned.

THE CLIMATE OF MANITOBA.

It may seem strange, says *The Colonies and India*, but it has been proved beyond a doubt, that the Canadian north-west enjoys a milder temperature in winter than the region to the south of it, in the United States. Continued observation proves that Manitoba frequently escapes the severe winter storms or "blizzards" which sweep over Minnesota and Dakota, and render travelling and outdoor work almost, if not altogether, impossible.

Mr. S. H. Harris.—The reply appeared in our impression of Sept. 25th, p. 523.

Tentator.—We do not see that there would be anything unprofessional in A. putting himself forward as a candidate.

HIGH-HEELED BOOTS AND SHOES.

To the Editor of THE LANCET.

SIR,—Will you kindly let me say a few words on the consequences of the present fashion of high-heeled boots and shoes, and especially of the unnatural situation of the fashionable heel?

I have at present under my care two serious cases of "sprained ankle," solely arising from their use. The parties tripped, and losing their balance, were unable to recover themselves without falling, which, in the one, resulted in partial laceration of the internal, and in the other of the external, ligaments of the ankle-joint, and both threaten to end in permanent partial disability.

Again, about a month since, I was consulted respecting a young lady, aged sixteen, whose parents were greatly alarmed at a supposed spinal affection under which they believed their daughter to be suffering. After an ordinary walk, but more especially after ascending the hills in the locality, she experienced a distressing feeling of nausea, and an amount of pain and heat over the dorsal and lumbar regions, extending, more or less, through the whole lower extremities, and followed by an amount of painful weariness that wholly disabled her for days after, the more muscular parts being painful on pressure. My professional knowledge of both parents and child guided my diagnosis and prognosis of the case. That the spine was all right, and the means of cure simple, I felt no doubt. I ordered the boots she generally wore to be brought to me, and found the heels raised *two* inches, tapering to the size of a shilling, and, to make matters worse, instead of corresponding to the situation of the natural heel, they were situated immediately under the arch of the foot. I recommended rest in the horizontal position for two or three days, and shoes with half-inch soles, of the breadth of the natural heel, and the toes broad in proportion, to be substituted for those previously worn. The cure was complete. No nausea, no weariness, no pain or discomfort, after a four-mile walk, have been experienced since.

In walking under the previous condition every intention of nature—anatomically speaking—was frustrated, and the symptoms complained of precisely those to be expected. Not only were the firmness of step and ease in walking lost, through the natural spring and muscular action of the foot being destroyed, but every muscle whose tendon extended to the foot must have been abnormally strained, the upright position of the body preserved under difficulties, and the centre of gravity and adjacent nerve-centres seriously irritated—a state of things which, I need not tell my professional brethren, if perpetuated from youth to womanhood, must inevitably end in permanent mischief of some kind, and the sooner the voice of the profession is raised against such an absurd and pernicious practice the better.

It certainly does not redound to the credit of our good sense or intelligence to see introduced and patronised what became a term of reproach to our ancestors a century and a half since.

I am, Sir, yours, &c.,

THOS. H. S. PULLIN, M.D.

Sidmouth, Nov. 1880.

Subscriber.—Lectures on Orthopædic Surgery and Diseases of the Joints, delivered at Bellevue Hospital Medical College. Published in London, 1876.

Mr. Stocken (Upton) had better apply to the Secretary of the Association, St. John's-gate, Clerkenwell.

POROPLASTIC JACKETS.

To the Editor of THE LANCET.

SIR,—I have a patient, aged about forty, with lateral curvature of the spine to right side. She has been using for the past five months, with some benefit, the poroplastic jacket, with, of course, the extending apparatus; but this is defective in one essential point at least—viz., that whilst compressing the bulging or projection of right side below and posteriorly, it at the same time equally compresses the left side, already contracted and drawn in. This of necessity it must do, being simply an encircling force, pressing equally on all points. What is wanted is an appliance which, whilst pressing directly upon the projecting curve below, would at the same time so operate on the upper portion of the spinal column as to draw it outwards, and not at all to press on the opposite or contracted side. Now, it occurs to me that if there be any appliance tried, and found by the profession to be more efficient for the above purpose than the poroplastic jacket (as for the plaster-of-Paris bandage I have found it to be worse than useless), I should be most likely to come to the knowledge of it by the publication of this letter in your widely-circulating journal.

I remain, Sir, yours truly,

Dunkineely, Ireland, Nov. 1880.

ENQUIRER.

NURSES FOR THE SICK POOR.

The following observations made by Earl Cairns, who presided at the recent annual meeting of the Nurses' Home and Training School, Belfast, will be perused with interest:—

"There are various forms which Christian charity takes, and I own there is no form of it comes so much home to the heart and feelings of everyone as the form which seeks to relieve sickness and suffering. We are all of us subject to sickness, and it is in sickness that one feels that 'touch of nature'—and sometimes a very rough one too—which 'makes the whole world akin.' We should be glad, many of us—I dare say all of us,—if we had the time, the opportunity, and skill, to minister to the wants of those in sickness. We have not the time, nor the opportunity, nor the skill, and we cannot all of us do this; but we can, on the other hand, support those excellent, self-denying, and energetic persons who devote themselves to this great and holy work, by kindness, by encouragement, by good wishes, and by prayers; and we can support them by providing them with the means with which they must be supplied in order that the work may be effectually done."

Mr. G. Burton.—We are not aware.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—With reference to some of the remarks made by "Two Students" in your issue of Nov. 27th, I think, in common with most, if not all, of my medical friends, ample time has already been allowed for the Guy's authorities to make arrangements for the carrying on of the great charity which they control. Surely, after the prolonged forbearance displayed by the medical staff, the onus of providing for the welfare of the patients might now fairly be thrown on the shoulders of the governors entirely. They, no doubt in common with most other people, have anticipated the possibility, or even the probability, of the resignation of the whole staff, and, it is to be presumed, are prepared to meet such an emergency, otherwise the want of forethought in the interest of hundreds of suffering poor would be most reprehensible. No feeling of irritation could to such an extent blind any body of men such as they. "Tantænam animis coelestibus iræ?" Let the medical staff, then, not be hyper-solicitous. The position taken up by the governors necessitates their acceptance of all responsibility. Let us see how they propose to support it.

Dr. Habershon and Mr. Forster might, I think, justly complain of the present inaction of their late colleagues who joined them in their act (the much-complained-of letter), but now refuse to share with them the consequences of that act, at all events as the consequences have turned out.

Without doubt, were the Guy's school to be closed the students would be received with open arms by all the other hospitals. This disagreement at Guy's is but another example of the ingratitude with which our professional services are so frequently, nay, generally rewarded. We give lavishly and with open hand; the compensation we receive only too often through the clenched fist. To such treatment the poor and struggling country practitioner has often to submit for his bread's sake, but no such hard necessity exists in the case of men so highly eminent as the staff of Guy's Hospital. Let us, then, have "more light" as to "coming events." I enclose my card.

I am, Sir, yours faithfully and obediently,

Dec. 1880.

ESPRIT DE CORPS.

BRONCHITIS COMPLICATED WITH DIARRHŒA.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent in THE LANCET of Nov. 13th, I would suggest that he administers to children with acute bronchitis complicated with diarrhœa during dentition, a mixture containing ipecacuanha powder, four grains; bicarbonate of soda, bromide of sodium, of each thirty grains; syrup and gum mucilage, of each two drachms: two teaspoonfuls to be given every three or four hours; aided by two or three doses of mercury-with-chalk, and a warm bath at bedtime, carefully administered. If the child is weaned, the nourishment should consist of mutton-broth with pearl barley boiled with it, a little milk and rice-water in about equal proportions, the temperature of the apartment being attended to. During convalescence a teaspoonful of cod-liver oil twice daily for two or three weeks completes the cure.

Yours truly,

Earl's-court-road, W., Nov. 23rd, 1880.

E. MAY, M.R.C.P.

TEMPERATURE IN RUBEOLA.

To the Editor of THE LANCET.

SIR,—I shall be glad if you will give me an opportunity of asking my medical brethren whether they have had any cases of rubeola in which the temperature has remained persistently high (say from 101° to 103°) a week after all the rash had disappeared; and also whether this high temperature has been accompanied by general tenderness in the lumbar region and in the wrist-joints. I should also like to know whether peeling has occurred frequently or not, and whether discharges from the ear have been noticed as one of the sequelæ.—Yours &c.,

Cardiff, Nov. 1880.

J. GARRETT HORDER.

ERRATUM—In our acknowledgment last week of the receipt of the pamphlet "Dress, its Sanitary Aspect," the name of the author was incorrectly given. It should have been Bernard Roth, F.R.C.S., not "Richard" Roth.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. S. Ringer, London; Mr. P. Hewett, London; Dr. Pye Smith, London; Dr. B. Yeo, London; Mr. T. Holmes, London; Dr. G. Johnson, London; Dr. G. Lawson, London; Mr. Baber, London; Dr. Davie, Dublin; Prof. Clay, Birmingham; Dr. Cook, Manningtree; Dr. Ridpath; Dr. Downes, Chelmsford; Mr. Craig; Mr. Faulker; Major Duncan; Mr. Butlin, London; Mr. Williams, Wigan; Mr. Hall, Swansea; Mr. J. The Brown Lectures.

FURTHER INVESTIGATIONS ON ANTHRAX
AND ALLIED DISEASES IN MAN
AND ANIMALS.*Delivered at the University of London on December 13th, 1880,*

BY PROF. W. S. GREENFIELD, M.D.

LECTURE I.

PROF. GREENFIELD commenced by stating that he had reverted to the subject of anthrax and anthracoid diseases because recent experiments were such as to throw an entirely new light on many of the problems relating to them, and to reverse views previously entertained, besides adding new, important facts. Anthrax had been investigated for many years; for it is the first disease in which a definite bacterial organism was found to constitute its specific contagium. If it can be brought under the category of epidemic diseases, the study of its specific organism is of the greatest value in the investigation of other like diseases; and the conditions of its propagation, of its maximum virulence, and of the influence whereby that virulence may be delayed or destroyed, become of the highest importance. The experimental study of anthrax has led to striking results in this respect, showing that the relative virulence of the disease, as propagated by inoculation or contagion, is identical in its properties with small-pox under like conditions; and if that is true the law holds good of nearly all contagious epidemic diseases—viz., that of natural recurrence, or recurrence in a modified form. The disease is more prevalent in man than is usually supposed, and although at present instances of it are confined mainly to woolsorters, it is yet widely prevalent where as yet its existence is unsuspected.

He would first describe experiments made during the past year which throw a new light upon its pathology. It was strange that so few attempts had been made at its prevention by protecting animals by inoculation. The striking results formerly obtained by small-pox inoculation had been obscured by the greater merits of vaccination in substituting a non-contagious for a contagious disease. It was only comparatively recently that any systematic attempt had been made to extend the principle of inoculation to other diseases; but there could be no doubt of its value in pleuro-pneumonia of animals, and now also as regards splenic fever. In his lectures last year he stated his intention to ascertain whether a bovine animal could be inoculated with a non-fatal form of the disease, so as to afford protection against any subsequently acquired or artificially produced attack. Dr. Sanderson and Mr. Duguid had shown that such inoculations could be practised; but their experiments, which had not been published, did not lead to the suggestion of protective inoculation, but rather negated this idea. Professor Greenfield then described his own experiments in detail. A cow (A) was inoculated with a second generation of anthrax bacillus, derived from the guinea-pig. There were no symptoms for twenty-four hours except slight swelling at the seat of inoculation. Forty hours after the inoculation the temperature rose to 104° (normal being 101°), and the animal became drowsy, stupid, and lost appetite. A slight evening fall of temperature to 102.4° was followed by a rise to 106.4° next morning, and for three days it ranged between 105° and 107°, the animal being seriously ill. There was very marked œdema at the seat of inoculation, subsiding on the sixth day. On the eighth day the temperature fell to 104°, on the ninth to 101°, and speedy recovery ensued. Six weeks later a second inoculation was performed, the fresh spleen of a guinea-pig dead from anthrax and swarming with bacilli being used. The temperature rose to 102.6° next day, but on the third day the animal was well. A week later a third inoculation was made on this cow, and at the same time another cow (B) was inoculated

for the first time. No result occurred in A, but in B there was rise in temperature on the second and third day, but no loss of appetite or local œdema; and on the fourth day the animal was found dead, and presented the post-mortem appearances of splenic fever, the blood swarming with bacilli. A fourth inoculation was performed on A three weeks later with the fresh spleen of a guinea-pig, swarming with bacilli, and again without result. Two weeks later a fifth inoculation from a sheep which had died of anthrax, resulted only in the formation of a local abscess. A calf (C) six months old was inoculated with the fifth generation of anthrax bacillus; nine days later it was reinoculated, this time with the first generation; local œdema, rise of temperature, and other symptoms followed, but recovery took place. Five months after a third inoculation produced no effect. Experiments were also made on two young heifers (D and E) about the same age and size; D was first inoculated by the cultivated bacillus of a third generation. Next day it was stupid and drowsy; and there was extensive local swelling; the temperature reached its maximum on the third day, when the constitutional symptoms were most severe; with the subsidence of the fever rapid recovery took place. Neither in this nor in other cases did any pustule form, nor had the local swelling any resemblance to the emphysematous swelling of "black quarter." The blood contained no bacilli. Ten weeks later an inoculation with the thirteenth generation of the cultivated virus produced no effect; and an inoculation with the spleen of a guinea-pig produced no symptoms beyond slight local swelling. E was inoculated five days after D with the eighth generation of bacillus. No symptoms occurred; nor after a further inoculation with the seventh generation, and one with the thirteenth, practised at the same time as the like inoculation on D. It being thought possible that protection might be conferred by inoculation with the very attenuated virus, each of these animals was, three months later, inoculated with half a drachm of blood from a man who had died of general anthrax (woolsorters' disease) thirty-six hours previously. The blood was still fluid and of natural colour, its corpuscles were natural, and it contained the characteristic bacilli, but no spores. Rodents inoculated with it speedily died. The heifer D, which had been successfully inoculated three months previously, suffered from no ill-effects after this severe test, beyond a slight rise of temperature the following day, and a small phlegmon. In E, however, very severe symptoms set in in twelve hours, and for some time life was threatened; but on the fifth day improvement set in, although the swelling was so considerable as to call for incisions to be made into it. The same two animals were submitted to another comparative test two months later, D being inoculated with the spleen, and E with the pericardial serum from a cow dying of splenic fever on a sewage farm near Bradford. No symptoms followed in either case.

It had been objected that, although such inoculation conferred protection against further inoculation, the animal might still be susceptible of the epidemic or epizootic disease. But there is ample evidence to show that animals insusceptible of inoculation do not spontaneously suffer from the disease, and that the disease in its epidemic form is really inoculated in some part of the mucous membrane. Striking confirmation of the protection by inoculation has recently occurred. Near Bradford the sewage of a mill and the adjoining village is carried almost directly to a small farm about a mile distant, and there distributed to some meadows on one side of a valley and stream, the fields on the other side not receiving any of the sewage. This sewage (containing as much as 2.6 per cent. of organic matter) is largely composed of the washings of wool from the mill, and that the wool contained anthrax poison was shown by the occurrence of four cases in the men washing the raw wool in April, one in May, and one in June. On May 1st the proprietor of the farm, who had procured twelve cows from Scotland, placed five cows (lot 1) upon the sewage farm, and the rest (lot 2) on the other field. On May 27th one of the lot 1 was found dead and two others ill. All the animals were now removed to the non-sewage fields, but on June 8th the eight were put on the sewage farm, and on the 30th the cow which had been ill was found dead. The rest were again taken off these infected meadows, but on July 2nd one of the second lot died suddenly from anthrax. Two sheep grazing on the sewage field also died. On July 13th the three animals above called A, D, and E were placed on these fields, and remained there, two of them till October 19th, and one till November 16th, quite free from disease. Meanwhile two

more sheep died from anthrax, and although the mills had been stopped the contagion still remained in these fields, for on November 23rd the proprietor placed some fresh cattle on them, having kept them on the other fields from the end of September. On December 2nd one of these animals died of splenic fever.

These facts are, of course, not absolutely conclusive, for it is difficult to obtain any absolute proof of the power of resistance acquired by any exposure to contagion; but there are few conditions which could have been more satisfactory in proof of the protection afforded by inoculation.

Professor Greenfield then described at length the researches arrived at in the same direction, and with similar results, by Pasteur, Chauveau, and Toussaint; and remarked that, to be of practical value, a method must be found to confer the maximum of protection with the minimum of risk to the inoculated animal. He had, therefore, instituted a series of experiments, on the modification of the anthrax poison, which he proposed to describe in the next lecture (and a note of which was read at the Royal Society on June 17th, some time before M. Toussaint made his method public at the Académie des Sciences).

Passing to the phenomena following inoculation, he remarked upon the constancy with which a local gelatinous oedema and rise in temperature (whether of fixed duration and degree observations were too few to decide) occur in the non-fatal cases; whilst in the fatal cases such symptoms were absent. They were also absent in the subsequent inoculations, so that the conclusion is that the swelling is not a mere inflammatory reaction caused by injection of irritant material, but as specific as the vesicle of vaccinia or the chancre of syphilis. It varies also with the intensity of the virus, and not with the material containing it, and its appearance may be looked upon as a favourable omen. He had failed to find bacilli in this gelatinous exudation in bovine animals as in rodents; and inoculations from the blood during the high temperature were inert, so that if bacilli were absorbed they must be destroyed. There was no definite information as to recurrence after mild attacks, nor on the question of individual proclivity and susceptibility. The resistance after inoculation is not complete, for it may be increased by further inoculations, and Chauveau has shown it may be overcome by enormous intra-venous injections. It cannot be that the pabulum for the maintenance of the life of the virus is exhausted, but it would seem as if the power of destroying the virus were intensified, and that a certain property innate in the system acquired increased activity by use. Chauveau shows that Algerian sheep, which have great natural power of resistance to the virus, have this increased by inoculation, and that if ewes are inoculated in the last months of gestation the lambs are insusceptible. The observations of Brauell and others, and in one case by Professor Greenfield himself—the blood and tissues of the foetus of an animal dying of anthrax were found not to contain bacilli, whilst those of the mother may swarm with them. So that immunity may be transmitted without contagion; and possibly this is due to a product of the virus, and not the virus itself being the factor capable of protecting by inoculation. If this be so, a new law of vast importance in contagious disease would be opened up. The fact of non-recurrence adds one more link between anthrax and the specific contagious diseases as distinguished from simple blood-poisoning; and gives encouragement to the investigation of its laws, in the hope of applying them in future to the less understood but more important and fatal human diseases.

GUY'S HOSPITAL. — The following is the reply of Dr. S. O. Habershon and Mr. Cooper Forster to the resolution sent them by the members of the Brixton Medical Book Society, a notice of which appeared in our last week's issue:—

“Dec. 6th, 1880.

“GENTLEMEN,—We sincerely thank the members of the Brixton Medical Book Society for the resolution passed at their meeting on Dec. 3rd. We highly appreciate the sympathy of our professional friends in the painful and difficult position in which we have been placed as seniors on the staff of Guy's Hospital. We could no longer remain in office without sacrificing the honour and the just claims of our profession.—We are, Gentlemen, yours very faithfully,

S. O. HABERSHON.
J. COOPER FORSTER.”

Clinical Lecture

ON

CARCINOMA OF THE SIGMOID FLEXURE.

Delivered at St. Mary's Hospital,

By ARTHUR T. NORTON, F.R.C.S.

A shilling and a sixpence arrested in the bowel at the seat of the stricture; perforation of bowel and escape of fecal fluid beneath the iliac fascia; pyæmic abscesses and secondary deposit of cancer in the liver.

GENTLEMEN,—R. L.—, a healthy-looking woman, aged forty-four, was admitted into the hospital on the 24th of January. She said she had enjoyed good health until the previous month. Owing to the symptoms exhibited at the date of admission the patient was entered as a medical case under the care of one of the physicians.

When first seen she complained of nausea and continual retching, but without vomiting; of great pain in the left lumbar and iliac regions of the abdomen, aggravated by pressure, and also of severe pain referred to a point midway between the tuberosity of the ischium and the great trochanter of the femur. For some days the symptoms remained unchanged. The temperature varied, being always above normal, sometimes 102°, and the variations were not regular, the highest point in the day being from time to time in the morning, occasionally in the afternoon and evening.

On the 13th of February there was detected deeply in the left iliac fossa, and reaching nearly as low as Poupart's ligament, a distinct swelling, excessively tender and somewhat fluctuating in character. This swelling could not be felt on a vaginal examination. On the morning of this day the patient had a distinct rigor lasting about a quarter of an hour. Retching and vomiting were continuous throughout the day, but the vomit was not stercoraceous.

On the 17th of February I examined the case again in consultation, and found what I described as an irregular, fixed, somewhat nodular mass on a level with the last lumbar vertebra three inches from above downwards, and an inch and a half from side to side. In the left iliac fossa was also an abnormal enlargement, tense and elastic, and of doubtful fluctuation.

On the following day the patient was put under chloroform, and the question of exploratory puncture was discussed, but I considered that the tumour with doubtful fluctuation lay so far away, and in itself was so slight in the elevation, that such a puncture would very probably prove a failure; whilst at the same time the necessity of making the puncture in very close proximity to the iliac vessels made the risk of the operation too great in comparison with any good results that might possibly be derived from it.

From day to day the patient suffered from severe rigors, followed by profuse perspirations. The tongue was brown, furred; the pulse 120; the bowels were open regularly, sometimes solid motion, and often diarrhoea.

On the 24th February the physician inserted a trocar, in order to ascertain the character of the fluctuating tumour, but only blood came away.

On the 26th I again saw the patient in consultation, and found the left side of the abdomen emphysematous, commencing around the seat of the puncture and extending some six or eight inches upwards. It was considered advisable to open down upon the tumour at once, and I therefore passed a knife into the point of the former puncture, and made an opening large enough to admit my finger. About ten ounces of frothy, yellow material, resembling typhoid fever stool, came away, and on inserting the finger within the aperture the cavity was traced under the psoas inwards as far as the pelvic cavity, and upwards as high as the last lumbar vertebra. The extremity of the cavity could not be reached by the finger, but as high as the finger could reach a somewhat extensive induration could be made out near the lumbar vertebra, giving to the finger a sensation such as an ulcerated surface. The wall of the cavity was

so greatly thickened by chronic inflammation that the outlines of the intestines could not be traced.

The fluid which escaped from the wound was not pus, though some pus was contained within it. It had the characteristic faecal odour, and was described by me at the time as the intestinal secretion mixed with finely divided aliment. On the following day the pulse was 135 per minute, feeble and fluttering, and the patient was in a state of extreme prostration. On the 5th of March, when last seen by me, her respirations were 40; she was unconscious and sinking. She died early on the following morning. At a post-mortem examination there was found chronic peritonitis in left iliac region, with considerable thickening. The lower part of the great omentum was adherent to the front and outer side of the sigmoid flexure, the medium of union being highly vascular. No general peritonitis; small intestine and stomach healthy. The sigmoid flexure was the seat of an indurated swelling, most marked in an annular manner, suggesting stricture of the gut at the centre of the swelling. A ragged aperture existed in the posterior part of the bowel, and this communicated with a huge abscess cavity occupying the whole of the iliac fossa, the upper part of the pelvis on the left side, and the lower half of the left lumbar region. This cavity contained a quantity of black sloughing debris, pus, and fluid faecal matter. The iliacus muscle was almost wholly destroyed, and the psoas was dissected out and surrounded by necrotic material, and its surface in great part destroyed. Beneath this muscle the abscess cavity had extended into the pelvis.

The calibre of the gut was diminished, admitting only the forefinger. The aperture leading from the gut to the abscess cavity was surrounded by an irregular and thickened margin, and for some three inches above the aperture the gut was both thickened and indurated. Contiguous lymphatic glands were enlarged, but whether from inflammatory exudation or new growth appeared doubtful. A shilling and a sixpence were found arrested by the stricture of the intestine, the two coins lying flat upon each other.

The liver was enlarged. At the under part of the left lobe was an irregular mass of cancer, two inches and a half in length by nearly the same in breadth. Another nodule, the size of a grape, was found in the substance of the right lobe. Scattered throughout the liver were scores of typical pyæmic abscesses, with sharply defined margins, without any surrounding induration, and containing a greenish-yellow material of creamy consistence. The size of the several abscesses varied from a pin's head to a small walnut. There were no pyæmic abscesses in any other organ.

Microscopical examination of the intestinal induration, and of the secondary deposit in the liver, proved them to be typical adenoid cancer. The alveoli were, in some parts, filled with cells, in others only lined by a single layer, the shape of the cells varying from round to well-formed columnar. There was a considerable amount of interstitial tissue, or stroma, in some places thickly set with very small cells, and others merely fibrous.

The above is the history of a case which, as you have perceived, is one of a very complicated character. My diagnosis at the first visit was cancer of either the vertebra or the sigmoid flexure, with adhesion of that bowel to the vertebra, but if the latter then not sufficiently altering the calibre of the bowel to promote any serious obstruction. Having come to the conclusion that the disease was malignant, it appeared clear to me, when a fluctuating tumour became defined, that ulceration of the bowel had taken place, with escape of faecal fluid. With my diagnosis I am called upon to say no other member of the staff agreed. It seemed to be the general opinion that an abscess was forming in connexion with the lumbar vertebra, but as there were many strange symptoms not usually coincident with that disease, the actual pathological change was considered obscure. I will enumerate to you the signs upon which I based my opinion that the disease was malignant, and explain my reasoning upon them.

1. A tumour could be felt located and measured, not even, but rather nodular, upon the surface. Those who considered the case to be an abscess looked upon this mass as an indurated extension of the disease.

2. The person had arrived at an age (forty-four years) at which an abscess in connexion with the spine is excessively rare, whilst cancerous deposits may be looked for.

3. The pain, although present in the left lumbar region, and aggravated by manifestations, was excruciating in the region of the hip-joint and in a point between the tuberosity

of the ischium and the great trochanter. The character of the pain had some weeks previously led the patient to apply to the hospital as a case of disease of the hip-joint. Now, this pain around the hip-joint is not at all such as occurs with abscess, but, strangely enough, it is precisely such as occurs in cases of malignant disease of the vertebra, verified now by me in five different cases, and it therefore acted as a strong incentive to me to examine carefully for cancer. In a clinical lecture given by me, and published in THE LANCET on Nov. 9th, 1878, I mentioned that in cancer of the vertebra or pelvis there is extreme pain in the hip, pelvis, and thighs. The pain has never, I believe, been referred to by other writers, and therefore no suggestion has been made as to the cause of this pain, but it must be remembered that cancer of the lumbar vertebra or of the sigmoid flexure, if attached to the tissues around, must implicate the lumbar plexus of nerves. In the instance now before us, when the bowel ulcerated and faecal escape took place, the cavity containing this fluid enclosed the main branches of the lumbar plexus.

4. The temperature variation was a prominent feature in my estimation in the diagnosis of cancer. The thermometer stood at normal on two or three occasions only, varying usually between 100° and 102°, but from time to time reaching 104°. The variations were irregular, sometimes high in the morning, sometimes in the midday or afternoon, and sometimes in the evening.

An abscess chart never assumes this form; if active and acute, it stands high persistently, and, if chronic, it is high in the evening and normal in the morning; whereas in cancer, as I have pointed out in former published lectures, the irregular elevations are often accompanied by pain, and are associated with exacerbations. Lastly, among the constitutional symptoms, retching and vomiting, and markedly severe rigors over many days, I could not look upon as signs of abscess. Retching and vomiting are common with cancer of the bowel, but concerning the rigors I could offer no explanation until at a later stage of the disease I determined that ulceration of the bowel had taken place with escape of faecal fluid in the connective tissue. Such an irritant, and I may almost add only such an irritant, could produce so severe a symptom, for in no disease have I ever witnessed rigors so severe, so lasting in each attack, and attacks extending over so many days, except in experimentation upon animals when putrid pus has been injected beneath the skin.

Now, if in this case an abscess had been forming either in connexion with the vertebra or as a result of pelvic cellulitis, the prominent symptoms to which I have referred would have differed very materially. I must at once put aside the question of acute abscess because of the absence of the sudden attack of inflammation, with accompanying signs—viz., sudden local pain, sudden elevation of temperature, and the constitutional signs of high fever, terminating rapidly in the formation of matter. Such was not the course taken by the disease under consideration. Again, I do not think it worth while to occupy your time in describing a case of caries of the vertebra in order to draw a comparison between that disease and the one before us. The age of the patient, the peculiar induration, or rather tumour, over the region of the vertebra, the position of the fluctuating tumour being beneath the iliac fascia, together with the temperature chart, were sufficient for me to withdraw my attention from the consideration of that disease. Now, there is a disease not uncommon in women—I mean chronic pelvic cellulitis—and which may be accompanied by secondary pyæmic deposits, and in such a case would closely resemble the case of the woman R. L.—. You may perhaps recall to mind two cases of pelvic cellulitis under my care—one in which the abscess made its way beneath the peritoneum up the front wall of the abdomen, and the other, in which suppuration extended through the left iliac fossa.

The former, when it came under our care, was already associated with pyæmic deposits and peritonitis, so that the rigors, retching, and vomiting forcibly brought to mind the case of R. L.—; but a careful examination accounted for every symptom. A vaginal examination detected a boggy mass between the vagina and rectum, extending upwards over the bladder to the front wall of the abdomen, over which its limit could be unmistakably delineated by percussion. A fine trocar inserted into the boggy mass referred to brought away fluid, but not pus. The cellular tissue, which had been slowly inflamed and thickened, was becoming gangrenous, afterwards proved by post-mortem examination.

It is interesting to compare these two cases, for certainly there was very great resemblance in their symptoms; but the diagnosis of the latter was rendered easy by physical examination, whereas in the former case physical examination exhibited a morbid condition, upon which opinions did not coincide.

The other case of pelvic cellulitis resembled the subject of our lecture, not in the symptoms, but only in the position of the tumour. The left iliac fossa was the seat of the abnormal enlargement—a disease which had commenced a few weeks after parturition, and which at the present time is suppurating. When she first came under our notice suppuration had not commenced, and we had to reason out the character of the somewhat hardened mass occupying chiefly the iliac fossa. The history of the case and the labour became the clue in which I found the diagnosis, whilst the character of the temperature chart, that of a chronic abscess—namely, high at night and low in the morning, without variation—left no doubt as to the exact pathological condition.

I have endeavoured to show you in this lecture that the case was an obscure one, on which there might well be different opinions expressed. That a comparison of the symptoms with those of caries of spine and with forms of cellulitis led me to doubt the probability of it being either of those two diseases, whereas a comparison with cases of internal cancer formerly under my care led me to decide it a form of that disease.

The peculiar coincidence of two coins being found imbedded in the cancer added somewhat to the difficulty of diagnosing the case, and also doubtless brought about an earlier fatal termination. It is probable that the margin of the coin was the cause of the ulcerative perforation of the intestine, and hence of the fluctuating cavity which threw the chief obscurity upon the case. How they came there did not transpire, or why they should have adhered together and permanently fixed themselves in the growth instead of passing away with the faecal excretion, which was not interfered with, is scarcely evident from the nature of the growth.

EYE SYMPTOMS IN LOCOMOTOR ATAXY.¹

By J. HUGHLINGS JACKSON, M.D., F.R.S.,

PHYSICIAN TO THE LONDON HOSPITAL AND TO THE NATIONAL HOSPITAL FOR EPILEPSY AND PARALYSIS.

THE author first alluded to the great number of very different symptoms in this disease, better called *tabes dorsalis*, since the gait might be normal. He referred to the fact that some of the symptoms were occasionally found in other diseases. At present we have to study the symptoms as they occur in association or in sequence. In this paper three well-marked non-ocular tabetic symptoms were taken and considered in connexion with certain ocular symptoms. Twenty-five cases in different stages furnished the material for the communication.

a. Non-ocular symptoms. (1) *The "lightning" pains.*—There is a succession of sudden, small, severe short pains in batches. As Pierret and Buzzard have pointed out, these pains may occur about the head, although they occur mostly in the legs, trunk, and arms. Charcot and others have observed eruptions in the parts seized by pains. Buzzard has published the case of a patient (whom he permitted the author to see) who, with every batch of pains, has a small crop of herpes; this patient has double optic atrophy and Westphal's symptom (absence of so-called patellar tendon-reflex), as well as the pains; he walks well. An interesting feature in this case is that the patient had for several years crops of herpes before batches of pain, and then always both together. It is most important to note that pains are denied by some patients, who, nevertheless, have them. Many patients see no relation betwixt their pains and their amaurosis or ataxy, especially if the pains come years before. This one patient strenuously denied having any pains, but it came out, as it were accidentally, that

he had had sciatica; really he had had true lightning pains. He had optic atrophy and Westphal's symptom. Many of those who deny pains will admit that they have long been subject to rheumatism or to neuralgia, or to "flying gout," and will describe these things so that it is certain they are lightning pains. It is often difficult to get a patient to fix his mind upon his pains. A patient, aged fifty-four, had recently continuous severe pain in the toes and sides of his feet. This he admitted to be one of the symptoms of his disease, but ignored lightning pains, which he had, on and off, for twenty years; those pains were, he would have it, "only gout." It was difficult to get him to attend to questions about them. He had had incontinence of urine nine years; difficulty in walking, according to his account, six months according to his wife, slightly for about eighteen months earlier; his gait was only slightly ataxic. There was Westphal's symptom. The ocular symptom was that his pupils, which were small, did not contract to light. It is to be insisted on that a patient may have for very many years the pains before any of the striking symptoms of *tabes dorsalis*. "I have recently seen a patient, about sixty years of age, who had pains which I concluded to be 'lightning' for about twenty years. His gait was normal; by most careful testing I could find nothing the matter with it. The patient had besides, of late years, attacks of what he called sickness, but really faintness, with intense depression for hours. That these were slight gastric crises I could not be sure; they possibly depend on derangement caused by very large quantities of opium he had taken for relief of pain. The narcotic taking was evidence of the severity of the pain; he began this practice many years ago. Hearing his account of pain, I looked for Westphal's symptom, and found it. He had an ocular symptom, too. The pupils did not contract at all to light, and, I thought, very sluggishly, during accommodation. I do not in the least doubt that this is a case of posterior sclerosis; Charcot and Bouchard report a case in which pain had been the only symptom; the necropsy showed commencing sclerosis of the posterior columns." (2) *Westphal's symptom* ("absence of knee phenomenon," "loss of patellar tendon-reflex").—"Everybody knows that smart tapping just below the knee in healthy people makes the leg jump up. As Westphal and Erb point out, this does not occur in the great majority of cases of *tabes*. There is no doubt of the correctness of this statement. The jumping up upon the tapping is usually called patellar tendon-reflex, but as this name involves a theory much disputed and not accepted by the discoverer of the symptom, I will call the loss of this so-called reflex 'absence of the knee phenomenon,' or Westphal's symptom. It is by no means easy to be sure of the absence of the knee phenomenon. We should bare not the knees only, but the legs, let the trousers down, and take off tight drawers; then we should make the patient sit on the edge of a table with his legs hanging loose, and hit carefully both with the hand and a hammer. I am quite certain that the knee phenomenon is said to be absent when it is not. It is admitted that in cases which are evidently not cases of *tabes*, Westphal's symptom is present. Thus in atrophy of the quadriceps the knee phenomenon cannot, for obvious reasons, occur. Buzzard has published a case of diphtherial paralysis, in which there was Westphal's symptom. On the patient's recovery from the paralysis the knee phenomenon returned. I have seen it absent in a case of diphtherial paralysis, but have not heard of the progress of the patient." (3) *The ataxic gait.*—Under this head the author gave briefly the explanation of the gait of *tabes dorsalis*, which he gave in THE LANCET, Jan. 30th, 1875, and the *Medical Times and Gazette*, July, 1873. He believes the so-called disorder of coördination to be a double condition—paresis of some movements and over-action of others. He illustrated by the duplex effects of paralysis of ocular muscles. A similar explanation has since been given by Pierret.

b. Three eye symptoms.—"One great question of interest is as to the frequency with which eye symptoms are the earliest symptoms. Since the Argyll Robertson's symptom does not inconvenience patients, it is hard to say whether it is ever first or not. I was never consulted for that symptom, although, as I shall mention shortly, I was once consulted for a condition somewhat like it. Excluding from consideration for the moment Argyll Robertson's symptom and Westphal's symptom, since we cannot learn anything of them from the patients' accounts, I found in nineteen cases that the earliest symptoms were as follows: in ten

¹ Abstract of a paper read at the meeting of the Ophthalmological Society of the United Kingdom, Dec. 9th, 1880.

cases pains, in six double vision, in one abnormal gait, in one optic atrophy, in one mental symptoms; probably the last was a case of general paresis. The pains are often neglected in taking note of the earliest symptoms; manifestly this puts all wrong; makes the case seem to begin months or years later than it really does." (1) *Paralysis of parts supplied by oculo-motor nerve trunks*.—Several cases were alluded to under this head. "A man aged sixty-three, who twelve months before had had paralysis of parts supplied by the left third nerve. I could find no symptom of tabes with one very important exception; this was Westphal's symptom. Not very long ago I should have had to say that he had no symptom of tabes. I could only have guessed tabes. Thanks to Westphal, I now feel sure that this patient is tabetic. It is important to say expressly that this patient's pupils acted well to light and during accommodation; he had no pains of any sort anywhere. He complained only of a heaviness in his head." (2) *Alterations of pupils*.—The common condition described is what is called the Argyll Robertson pupil; the pupil does not act to light, and does act during accommodation. This has been observed in tabes by Hempel, Vincent, Erb, Hutchinson, and others. It is a double condition, negative and positive, and in this way resembles the so-called disorder of coördination of locomotor movements. Erb calls the condition of inactivity of the pupil, "reflex pupillary immobility," and advances an hypothesis as to its fundamental community of character with Westphal's symptom. That hypothesis, however, had been previously made by Buzzard; he points out that both in Westphal's symptom and in the Argyll Robertson symptom there is loss of a reflex movement when the more voluntary movement is retained. Buzzard's hypothesis seems to harmonise with the explanation suggested as to the peculiarity of the gait. It must be remembered that we have not merely an affair of light and pupil. It is well known that brisk cutaneous irritations cause the pupil to enlarge; pinching a comatose man will often enlarge his pupils. Erb tells us that the pupils inactive to light in cases of tabes are not affected by such procedures; he says, too, that they are not affected during lightning pains. Frequently the tabetic pupil when inactive to light is myotic also. We have in all cases to consider the size as well as the immobility of the pupil; we must remember in this regard that the senile myotic pupil contracts to light. "Although much impressed by Buzzard's generalisation already mentioned I adopt no theory on the duplex condition of the pupil. I show a diagram copied from a paper by Erb (Seguin's *Archives of Medicine*, Oct. 1880) which gives that physician's view of the central conditions corresponding to the double pupillary condition. The following case is, in my experience, a very rare one. A woman aged twenty-six was sent to me simply because her right pupil was larger than the left. It had been so three years. The right pupil was dilated, and absolutely motionless to light, and also during accommodation. Yet her ciliary accommodation on this side was perfect. This was severely tested by Mr. Couper. She could read No. 1 Jaeger from fourteen inches up to five, or by effort to four. The field was perfect. The fundus was normal, except that the veins were large, and convoluted at the disc, probably physiological; the media were clear. Her sight with this eye was perfect. The pupil of the left eye was most active, and of normal size; the left disc was slightly paler than the right; the veins as on the right; macula normal; doubtful slight limitation of nasal part of field. She could read Jaeger No. 2 with the left eye, but the centre syllable of a long word seemed blurred. This case puzzled me. She seemed to be in perfect health except for the ocular abnormalities mentioned. It occurred to me to test her knees. Neither I nor Mr. Couper found the smallest trace of the knee phenomenon. Several times did I re-examine into this, and pertinaciously inquire for other symptoms of tabes; there were no other symptoms of any kind. Except for the two things mentioned she is in seemingly perfect health." It is not said of Argyll Robertson's symptom that it is peculiar to tabes. It may be found in general paresis of alienists, at least reflex pupillary immobility, less frequently is there myosis, and the size of the pupils is more often unequal. Erb has found the pupillary condition in patients who had no other nervous symptoms, as well as in nervous affections which could neither be classed as tabes nor as general paresis. Again, it is not said that the action to light may not be present in very well marked cases of tabes. A man sixty-five had, as he was told by Pagenstecher, paralysis of the right external rectus in 1874; there

was a return of double vision from some cause in 1876. He was subject to pains in his legs, his gait was ataxic; there was Westphal's symptom. He was obliged to carry a catheter to draw off his water. This patient's pupils do act to light. This was observed by Mr. Laidlaw Parves also, to whom the patient was sent for deafness. The following statement refers to cases from the pupil point of view. There were thirteen cases in which there was no optic atrophy. In ten of them the pupils did not act to light (in one case the pupil on but one side was inactive and was so in all ways). In nine of the ten cases of inactive pupils there was Westphal's symptom. Now as to paralysis of the oculo-motor nerves in the same thirteen cases. In one case with normal pupils and Westphal's symptom there had been paralysis of the third nerve. In one case of inactive pupils with Westphal's symptom there had been temporary double vision. In another case with inactive pupils and Westphal's symptom there was paralysis of one sixth nerve. (3) *Optic atrophy*.—Tabes dorsalis is a disease which, like general paralysis, rarely occurs in women. "When clinical assistant at Moorfields, about twenty years ago, I was struck with the fact that many of the men who had 'white atrophy' of the optic discs had also pains in their legs—the pains were lightning pains. Later on, making a distinction as to the kind of atrophy, I concluded that the pains were a symptomatic link betwixt 'uncomplicated amaurosis' and locomotor ataxy. This relation had been previously noticed. In the *Medical Times and Gazette* of Sept. 1st, 1866, I wrote: 'We have (1) amaurosis without pains in the legs; (2) amaurosis with pains in the legs only; (3) amaurosis with pains in the legs and difficulty in coördinating the legs; (4) pains in the legs and difficulty in coördinating the legs, without amaurosis; (5) amaurosis without pains in the legs and with difficulty of coördination. I could now put five patients in a room showing the above sets of symptoms.' The term 'amaurosis' meant then atrophy which did not follow neuritis. I mention what I observed not with any view to priority, having none, but because what I then said, some fourteen years ago, was denied, and the authority of Duchenne, that the amaurosis in locomotor ataxy presented quite the ordinary features of atrophy of the optic nerve as it occurs from other causes, was quoted against me." The atrophy is now more particularly described as grey degeneration, and is supposed by Charcot and others to be parenchymatous. The peculiar limitation of the field of vision in cases of the atrophy in tabes is significant when we consider that the developed disease is in great part one of the locomotor system. The limitation would seem to correspond roughly to certain ocular deviations from cerebellar disease, in the way that hemiopia does to lateral deviation of the eyes from cerebral disease. In all cases of optic atrophy we should inquire for the pains, test the knees whether gait be abnormal or not. The pains are often bridging symptoms, betwixt so-called uncomplicated amaurosis and tabes. Charcot says that so far back as 1868 he pointed out that the great majority of women admitted into La Salpêtrière for amaurosis have sooner or later manifestations of tabes. He mentions one case in which the amaurosis preceded the pains ten years. Gowers has seen a case of tabes in which optic atrophy preceded other ataxic symptoms twenty years. In the twenty-five cases mentioned there were twelve of optic atrophy. In two there were also ocular paralysis, and in one a history of it; in nine there was Westphal's symptom. In one of the three without this symptom there had been no pains; gait was slightly ataxic. In the second there had been double vision ten years ago; there is now paresis of the left third nerve; this patient had pains; his gait was normal. The third case was one of atrophy of one disc, with limitation of the field outwards and downwards; this patient saw green as grey, and red as reddish-brown; he had pains; his gait was good.

SOUTH LONDON SCHOOL OF PHARMACY. — The Medals and Certificates were presented to the following successful competitors for the first B. Course on Dec. 11th, 1880:—Medal, Senior Chemistry, Mr. Preston; Medal, Junior Chemistry, Mr. Cracknell; Certificates, Junior Chemistry, (equal), Messrs. Llewellyn and Haines; Medal, Botany, Mr. Fisher; Certificate, Botany, Mr. Frey; Medal, Materia Medica, Mr. Llewellyn; Certificate, Materia Medica, Mr. Cracknell; Medal, Pharmacy and Practical Dispensing, Mr. Haines; Certificate, Pharmacy and Practical Dispensing, Mr. Fisher.

A SUGGESTED IMPROVEMENT IN DUPUYTREN'S OPERATION FOR ARTIFICIAL ANUS, AND A SUCCESSFUL CASE TREATED BY IT.

By ARTHUR E. BARKER, F.R.C.S. ENG.,

ASSISTANT PROFESSOR OF CLINICAL SURGERY AND ASSISTANT-SURGEON AT UNIVERSITY COLLEGE HOSPITAL.

MY object in recording this case is twofold. Firstly, instances of cure of artificial anus by Dupuytren's method appear to be rare, if one is to judge by published cases in recent years. I may mention further that, among my surgical colleagues and friends, I have on inquiry heard of only one instance in which such a cure was attempted for this malady, and this attempt proved rapidly fatal. Secondly, I have in this case adopted a measure which, if it is to be regarded as having contributed to the perfect cure of the condition, appears to deserve trial in other similar cases.

No one who carefully reads Dupuytren's masterly essay upon the subject "Anus contre Nature," published with his "Leçons Orales de Clinique Chirurgicale," can fail to be impressed with the immense amount of labour and thought which he bestowed upon it, leaving but little to be done by others after him. But there is one point in his experience which, he frankly admits, shows a weak spot in his procedure. He tells us that though, by the use of his enterotome, it is easy in the majority of cases to restore the communication of the stomachal with the anal end of the gut so as to direct the flow of fæces into the latter, it is still a matter of extreme difficulty to prevent a certain proportion of fæces from escaping by the old opening in the abdominal wall, and yet more difficult to induce the latter to close thoroughly. I translate his remarks on this point:—

"It is something, no doubt, to have re-established a communication between the two ends of the intestine, and to have placed them in a position to bear without accident a compress which compels the contents to pass from the upper to the lower part of the gut. But something, I confess, remains to be desired. We have still to find a means of causing an opening in the skin, now become useless, to cicatrise in all cases. I am so impressed with the necessity of discovering some means of the kind that I do not hesitate to propose this as a study to the rising talent of our schools. . . . And I declare without hesitation that the discovery of some method which should finish promptly and without danger, and in every case, the cure of this disgusting malady, would be worthy of being considered one of the most important achievements of which the healing art can boast."

Dupuytren's statistics in regard to this operation are as follows:—He himself operated on twenty-one cases. To these he adds twenty more either published or communicated to him. Out of these forty-one three died and thirty-eight recovered without any grave accident. Of these thirty-eight, larger or smaller fistulæ persisted in nine in spite of all efforts to close them, and required the constant use of bandages to prevent a more or less abundant escape of gas, bile-stained fluid, or even fæces. But twenty-nine were completely and radically cured within the space of from two to six months.

In the treatment of the subjoined case a method was employed which appears to me to promise something at all events in the way of preventing the escape of feculent matter by these fistulæ, and as enabling the latter to close, and this without exerting that pressure upon the opening from without by pads, bandages, &c., which has hitherto been found ineffectual if not unbearable. It is impossible, of course, to say whether in this case the good result was due to this measure or not. My own impression is that it was contributed to, at all events, by it. The case is briefly as follows:—

S. L., aged twenty-five, labourer, admitted into University College Hospital on Feb. 3rd, 1880, for a fæcal fistula, the result of strangulated hernia more than a year before. He was here once before, fourteen months ago, but was discharged again in the hope that the fistula would close spontaneously. This it had not done up to three months ago, but since then it nearly closed, and for some six weeks he

only passed flatus by the opening, but no liquid. The latter, however, commenced to be discharged again from the opening on Dec. 28th, 1879, in varying quantity.

Feb. 5th.—Present state: There is a puckered cicatrix in the right groin below Poupart's ligament and well outside the pubic spine. In its centre is a fistula discharging light-yellow fæcal matter mixed with pus. When the abdomen is pressed upon the scar is dragged backwards as though by adherent intestines, and feculent matter is at the same time forced out in a jet to a considerable height. The bowels are opened on an average about three times a week.

16th.—A sea-tangle tent was passed into the opening on the 14th, and removed this morning. A finger can now be introduced. Patient feels quite well; has not passed a motion by the rectum for two days.

18th.—I examined the case carefully for the first time this morning. The little finger, passed into the fistula, entered as far as the middle of the second joint. Two constrictions were then felt, one at the skin opening, another about three-quarters of an inch deeper, or corresponding to the middle of the last joint of the little finger. The tip of the latter touches the usual "spur" of mucous membrane, which reaches as far as the latter opening. To the left of this "spur" the anal portion of the gut is felt passing almost directly backwards, but slightly inwards, and to the right of it the stomachal end passing towards the cæcal region. Catheters passed into the two portions of the gut demonstrate the same thing. After this examination some swelling and tenderness are noted about the opening, but the general health is good. No fæces pass now by the rectum, but flatus is still expelled that way.

27th.—To-day the first motion by the rectum for fourteen days was passed.

On March 3rd, hoping that a simple operation might be sufficient, I placed the patient under an anæsthetic, and pared away the old cicatricial tissue from around the fistula, making a wound of about two inches long, and one deep. I then passed five harelip pins deeply through the walls of the wound, and drew its edges together with figure-of-8 sutures. These were covered with collodion, and a sand-bag was laid over all. The next night after this the patient was rather restless, but nothing came through the wound, though flatus escaped by the rectum.

March 5th.—Bowels quite quiet; slight pain about the wound; flatus per anum.

6th.—Sleepless night; temperature 99·8°; complains of pain as the fæces force against the wound. He thinks that they pass it, and reach the lower part of the gut. On examination I found that a small quantity of watery fæces had worked out under the collodion. I therefore drew out all the pins, leaving the wound otherwise undisturbed, with the sutures and collodion *in situ*; bowels unaffected by opium in free doses.

8th.—Wound broke open yesterday morning, and fæces discharged as before. The gap is now three inches long and one and a half wide, and the opening into the gut freely exposed.

10th.—Had a small motion per rectum after an enema; also on 12th, 15th, 17th, 19th, and 23rd, but only after enemata, and very scanty, while large quantities of fluid matter escape constantly by the artificial anus.

27th.—For the last few days patient has been able to control the flow of fæces from the groin to some extent by an arrangement of pads, which reduce the size of the opening somewhat, not very much escaping, and as a consequence has passed a good motion per rectum this morning.

April 8th.—A small motion passed on the 4th, but nothing since, except after enemata. Wound smaller, but still discharging fæces.

On April 22nd I operated in the following way. The artificial anus was first enlarged by forcing the finger into it; then, feeling the "spur" of mucous membrane with the little finger, I passed a Wells's artery forceps into the opening, one blade into the anal, and one into the stomachal portion of the gut. The "spur" being now between the blades, as I assured myself, I nipped it tightly until the catch of the forceps was secure. A dressing of lint and carbolioil completed the operation.

26th.—Catch forceps came away this morning at ten o'clock, bringing away between their blades a piece of the tissue of the gut quite necrosed, and of the exact size given in the woodcut (Fig. 1). In the afternoon I again applied them in the same way, but this time taking up more of the "spur" in their grasp.

27th.—Slight tenderness in right iliac region. Temperature 99° 6'.

28th.—Some tenderness and some headache. Temperature 99° 3'. Forceps came away in the afternoon, bringing away

a portion of mucous membrane between the blades, of the size given in Fig. 2.

Diagram (about half natural size) showing condition of parts before operation. *a a*, Abdominal wall. *b*, External orifice of fistula in latter. *c*, Internal ditto. *d d*, Intestine. *e*, "Spur" in latter directing contents into fistula. Arrows indicate the direction of flow of feces.

29th.—Feels as yesterday.

30th.—Very well; all tenderness gone from iliac region; tongue clean. Temperature 98° 8'.

May 6th.—Yesterday afternoon, having patient under the influence of ethedene, I inserted an india-rubber valve (Fig. 4, *f*) within the intestine in such a manner as to lap

Diagram (lettered as Fig. 3) showing condition of parts after operation. *e*, Remainder of "spur" after removal by forceps. *f*, India-rubber valve *in situ*, closing internal orifice of fistula. *g g*, Silver stitches holding valve by both ends *in situ*.

up against the internal orifice of the fistula. It was fastened in this position to the skin by a single wire-stitch at each end (*g g*), passing through the latter in such a way as to secure it. The pressure of the feces against this valve was relied upon to make it fit still more closely to the curves of the opening. The valve itself was thin and flexible, about one and a half inches long by five-eighths of an inch broad, and was inserted with the double object of giving the fistula rest, on the one hand by preventing the feces from escaping that way, and, on the other hand, of keeping the newly-notched spur of mucous membrane from recontraction by directing the full stream of feces against it until it was soundly healed. The first of these objects was attained for several days, but at last a little gas and feces escaped under the lower edge of the rubber valve, and at the end of a week the fistula seemed to be enlarging a little at its lower border. I therefore removed the rubber slip through the opening. My intention had been to allow it to remain until the fistula had closed over it, and then simply to cut one

end of the wire stitches, draw them out, and so allow the slip of rubber to come away by the rectum with the usual motions.

A week after this the fistula is noted as "healing quickly," and a fortnight later as "nearly closed." After this it required to be touched two or three times with lunar caustic to stimulate its deeper parts, and twice with Paquelin's cautery. On June 29th, or within eight weeks of the last operation, the wound was quite closed. The patient now rose every day, and soon went to the country. He returned some two months later to show himself, when the scar was found by myself and colleagues to be perfectly secure, and he himself in rude health. He volunteered the remark that since the operation he had lost all that sensation of "internal straining" about the seat of interruption in the gut which had troubled him formerly as the contents forced themselves against the narrowed spot on their way to the anal portion. He also said that he felt as well as ever he had felt in his life, and had now no abnormal sensation at all in the abdomen.

It appears to me probable that whatever part this valve may have played in effecting this very complete cure of a very troublesome fistula, it may be found useful in other similar cases. I think in another similar case I should employ somewhat thinner rubber, and perhaps also modify the shape of the valve somewhat.

I cannot conclude without thanking my colleague, Mr. Berkeley Hill, for kindly transferring this case to my care.

Harley-street.

FURTHER OBSERVATIONS ON STERTOR; ITS PATHOLOGY AND TREATMENT.

By ROBERT L. BOWLES, M.D.

(Communicated by CESAR HAWKINS, F.R.S.)

In the forty-eighth volume of the Transactions of the Royal Medical and Chirurgical Society is a paper entitled "Observations on Stertor." Since the publication of that paper, if I except a paragraph in the article "Chloroform," in Holmes's System of Surgery, I know of nothing which has been contributed to medical literature on this subject.

In my first paper only three forms of stertor are defined, Palatine, Pharyngeal, and Mucous Stertor. Professor Lister refers to a "laryngeal stertor," as occurring during a certain stage of the inhalation of chloroform, but as it has no practical connexion, so far as I am aware, with the apoplectic and its allied conditions, we will at present dismiss it from further consideration.

The forms of stertor, then, which have a direct connexion with the apoplectic state are—the palatine, arising from the vibrations of the soft palate; the pharyngeal, from the gravitation of the tongue into the back of the pharynx, and the mucous stertor, from the presence of mucus or other fluids in the larger air-tubes. These three varieties, whatever their remote cause, are the immediate result of a local mechanical condition—a condition which may always and at once be changed, to the great relief of the patients, and sometimes to their permanent recovery. Since adopting this method of management many other points have developed themselves of the utmost practical importance both to the surgeon and to the physician.

CASE 1.—In October, 1863, Mrs. S— was seized with apoplexy. On my arrival there was a partial return to consciousness, and the left side was found to be paralysed. There was pharyngeal stertor when in the recumbent posture, and she appeared uneasy when placed on her right side, so she was placed on her left, when the stertor ceased. A blister was applied to the nape of the neck, and she remained in this position for nine days. She was now better, and spoke to me. Fearing a bed sore, I desired the nurse to change her position by turning her from her left to her right side. Soon after this was done she was distressed for breath, and the countenance became livid. On my arrival I found the difficulty of breathing gradually increasing, the blistered surface and the ear upon which she had lain of a dark purple hue, and the pulse, which had before been weak and irregular, full and bounding. There were large mucous râles

1 A paper read at the Royal Medical and Chirurgical Society, May 10th.

over the whole chest; she was quite unconscious, and death from suffocation was imminent. Finding that these symptoms supervened upon the change of position, I had her replaced upon her left side, and immediately the pulse sank, the mucous stertor ceased, the breathing was relieved, the lividity of countenance passed away, and the blistered surface, which had been almost black, resumed a bright cherry-red colour. This additional shock, however, proved too much for her, and she died the same day, peaceful and conscious.

The salient points of this interesting case are: (1) That pharyngeal stertor ceased when the patient was placed on her side; (2) that there was a slow but gradual improvement subsequent to this; (3) that mucous stertor and imminent death supervened when she was placed on the opposite side; (4) the instant relief on resuming her original position; and (5) that a return to consciousness was coincident with the cessation of stertor; in other words, on the removal of the respiratory difficulty.

On a careful examination of the chest after she became quiet, I found all râles slowly fade away from the right side, or that which was uppermost, and the natural breathing return; but the left lung, which had been dependent throughout, was dull on percussion and deficient in respiratory murmur. The explanation now became clear—viz., that the dependent lung had become filled with some mucous fluid, and that on changing the side the fluid, by gravitation, was finding its way across the trachea to the opposite lung, but in doing so it had been churned into foam by the ingoing air, giving rise to mucous stertor, and that this foam, by filling up the larger bronchial tubes, was quickly causing suffocation with all its usual results.

As a point of management, then, in a case of apoplexy, it would appear necessary to keep the patient on one side, and not to change it; but which side should this be? Healthy people when lying on their side breathe chiefly with the side which is uppermost; for the intercostal and other thoracic muscles of the lower side are fixed between the weight of the body and the bed, and the breathing of this side is almost entirely diaphragmatic.

CASE 2.—Dr. Fitzgerald during his attendance on a case of cancer of the brain finding the breathing much oppressed by mucus in the air-passages, at my suggestion placed the patient on his side, when he became suddenly so much worse that he thought he would have died instantly. Dr. Fitzgerald repeated the experiment with exactly the same results, and he found that the difficulty arose from mucus in the trachea and larger air-tubes. It was afterwards discovered that the paralysed side was placed upwards. Unfortunately, only the head was examined after death; but I have reason to believe that in hemiplegia from progressive disease of the brain a low form of inflammatory action takes place in the lung of the affected side from disturbed innervation of the pneumogastric nerves.

In a recent case of tubercular mass in the centre of the brain, which was under my care, this was the case, and precisely the same distress as above-mentioned occurred from mucus when the paralysed side was placed upwards. It must be remembered, too, that in placing the paralysed side downwards the injured side of the brain is upwards, and therefore relieved from congestion, a condition always liable to occur when an injured part remains dependent.

Apoplexy, with much mucous stertor, is, I believe, always of the most grave and dangerous character, for it indicates, as well as muscular paralysis, loss of function of such vital nerves as the pneumogastric, and, I believe, the time will soon come, now that cases can be so simplified by the removal of stertor, that by a careful consideration of the functions of the various nerves a very accurate diagnosis and prognosis will be arrived at even in the early stage of apoplexy.

CASE 3.—Mrs. W—— was found lying on her back breathing stertorously and with great difficulty; the trachea was filled with frothy mucus, and she was almost in a state of collapse. She was turned on her right side, when the stertor and difficulty of breathing ceased. Seventeen hours afterwards she was lying quiet and comfortable; the depending cheek was dusky and congested, the upper cheek pale. She was now turned on her left side; the difficult breathing immediately returned, and both sides of the face became highly congested; the breathing was shallow and large moist râles were present in both sides of the chest; on resuming the original position all difficulty ceased. She died the next morning.

The following case would, I believe, have terminated fatally but for the careful management of position.

CASE 4.—Mrs. S—— was seized on Sept. 24th, 1867, with left hemiplegia. She was unable to speak or to masticate, and could only swallow liquids with much difficulty; the pulse was 80, and very feeble. She was placed on her left side. On Sept. 28th (four days after) the respiratory murmur on the left side was shallow and feeble, there were some râles, and the percussion sounds were dull. She was turned on her right side, when immediately great distress of breathing and mucous stertor supervened; this gradually disappeared on replacing her on her left side. When turned on her back, for the use of the bed-pan, mucous stertor commenced, and it was noticed that in this position the intercostal muscles and the diaphragm acted more feebly than on the unparalysed side. On Sept. 29th there was a little more power, and she was less excitable. The respirations, which had been 56, were now 44. She was able to remain half an hour on the right side before the difficult breathing commenced. The following day she was still better; and the dribbling of saliva, which had been very great, ceased, but she still had no control over her bladder or rectum.—Oct. 6th: During the last week she has slowly improved. Several experiments of change of position have been made, and it was found that as her power returned she could remain longer on the right side before the difficulty of breathing commenced, and now can remain an hour and a half in this position. She speaks better, eats and sleeps better. Tongue is cleaning; bowels open, but she is still unable to retain her water. Pulse 80, respiration quiet and natural; on the right side the respiratory murmur is natural, on the left there are still a few râles, but the resonance is good, and the air enters more freely. Power is returning to the hand and face.—March, 1870: The patient is still alive and well, but has a good deal of weakness on the left side.

Remarks.—In its early stage this case was most critical; had a little extra strain been put upon her, she must have died, and no strain could have been worse than the persistence of a condition (stertorous breathing) which would indirectly cause obstruction in the jugulars. In the supine posture, from the paralysed and insensible condition of the pharynx, much of the saliva which dribbled away in the lateral position would have entered the trachea, and added to the trouble. Sir James Simpson, in writing of the treatment of phlegmasia dolens, says: "Position is one of the most powerful means in the treatment of many diseases; attention to this point is frequently of more importance, and affords more satisfactory results, than the use of any kind or quantity of drugs." In no case is this opinion of Sir James Simpson so aptly illustrated as in certain affections of the brain and air-passages. Dr. Bence Jones, in writing to me on this subject, says: "The case I mentioned to you was one of extreme hemiplegia of the right side, for the first few hours with perfect clearness of mind, passing in twelve hours into complete coma, with the most intense and distressing stertor, lasting for many hours. This was immediately stopped by changing the position of the patient to one side. But it had no known effect on the progress of the case. The total duration, I think, was not forty-eight hours. The gentleman was about sixty-two, pale and rather sickly, and had always feared apoplexy."

Mr. Reid of Canterbury, and many other of my friends, have reported to me cases of apoplexy in which, on the change of position, stertor has ceased, and the patients have died peacefully and quietly, to the great relief of the distressed and sorrowing relatives. I have never in my own practice failed to do away with stertor by position and management.

CASE 5.—At a medical meeting in May, 1862, after urging my views on stertor, Mr. Francis of Boughton stated that he had just left an old lady dying from apoplexy, who had been in a state of stertor for many hours. At the November meeting in the same year he informed us that the old lady was still alive and well. On his return home he found her just as he had left her, dying as he believed. He changed her position, the stertor ceased, and she gradually but perfectly recovered.

CASE 6.—Mr. Eustace Carver of Melbourne, a former house-surgeon at the Middlesex and Nottingham hospitals, and a careful observer, was called to Captain B——, in deep stertor and moribund. Life was evidently more a question of minutes than hours. The position was changed, the stertor ceased, and the old gentleman lived nine months.

CASE 7.—Dr. Lewis of Folkestone was sent for to Mrs.

F—, aged sixty-seven. He found her in bed in the apoplectic condition. There was total loss of consciousness, the pupils were fixed, but there was slight reflex action on touching the eyeball, the face was turgid, the cheeks were puffed out on expiration, and there was deep pharyngeal stertor. On being placed on her side the stertor ceased and she gradually improved. In twelve hours she had perfectly recovered consciousness, the respiration was normal, the face very pale, the pulse quick and feeble; there was no paralysis. The action of the heart was feeble, but there was no murmur.

CASE 8.—I was called in August, 1859, to a boy who had fallen on his head from a height. I found him lying on his back snoring, senseless, and collapsed; pulse irregular and pupils alternately contracting and dilating. The mouth was half full of vomited matter. On turning him on his side the snoring (palatine stertor) ceased, he was sick several times with comparative ease. Presently he began snoring whilst he was on his side, his chin was bent upon the sternum; on straightening the neck he was quiet. The boy slowly recovered. On three different occasions in my own practice I have been summoned to cases of apoplexy with stertor, in which the patients recovered, two with and one without paralysis.

Case 4 demonstrates that as power returns to the brain the pneumogastric and probably also the sympathetic regain their power, and effusion into the lung ceases; and, moreover, that the lung is not injured by remaining inactive and filled with mucus for a long period.

(To be concluded.)

NOTE ON THE DIAGNOSIS OF CAVITY IN THE LUNG.

By SOLOMON CHARLES SMITH,
SURGEON TO THE HALIFAX INFIRMARY.

I HAVE recently met with a peculiar physical sign of deep-seated cavity in the lung, of which I can find no mention in any of the books within my reach, and which seems worthy of being placed on record. It is a sound synchronous with the cardiac systole, not necessarily heard over the lung, but distinctly audible in the trachea, and even without the stethoscope when merely standing opposite the patient, and obviously produced by the impact of the contracting ventricle against a neighbouring cavity, expelling such a puff of air as to produce a sound in the bronchus and trachea.

My first patient was a man suffering from cough, expectoration, and shortness of breath. While watching the expansion of his lungs I heard a bruit synchronous with the first sound of the heart; it was short and soft, but plainly audible when we were about eighteen inches apart. On applying the stethoscope over the heart nothing abnormal was heard, but over the lung to the left the bruit was easily perceived. Systolic bruit over the left upper lobe is, however, no strange thing in phthisis, but on tracing it up it was loudly audible in the trachea, and on careful observation it was plain that the sound was conveyed outwards through the air-passages. Easy respiration did not interfere with its production, but on breathing deeply or quickly it was interrupted during inspiration.

The other physical signs were dulness, diminished respiration, and expansion, with moist clicks over the upper five inches of the left lung, and some tubular cough sound at the third interspace.

In my next case the physical sign I have described was not so well marked—that is, it was more easily interrupted by inspiration, and could not be heard quite so far from the patient; but, on the other hand, its connexion with a cavity was more completely demonstrated, the presence of a vomica being proved by a concurrence of many physical signs.

I do not at all wish to add another to the many sounds which have been described as occurring in cavities in the lung; if this were audible only over the position of the vomica it would be a matter of no great interest. Any importance it may possess arises from its being transmitted to the ear through the air-passages rather than through the chest walls, and thus being audible even when the disease is deeply placed. I may add that in auscultation of the trachea and larynx a flexible stethoscope is of great service.

Halifax.

AN UNUSUAL CASE OF CONGENITAL SYPHILIS.

By M. PRICKETT, M.D.

THE following case appears to me of so much interest both from its rarity and its importance as to deserve publication; especially so as I am unable to find any records of precisely similar symptoms.

Mr. — contracted syphilis three years ago; a chancre developed, and in due course of time mild secondary symptoms followed. These soon disappeared under treatment, which was continued for about six weeks, and the disease appeared eradicated. He remained in good health until his marriage a year ago; shortly after which, however, a skin eruption of doubtful nature developed itself. This was treated without avail by a large variety of remedies, amongst which were mercury and iodide of potassium; but I am unable to learn how long they were persevered with. As the eruption got considerably worse a specialist was consulted, who pronounced the disease to be psoriasis, but of a non-specific character. In spite of his treatment the eruption spread until, three months ago, his legs and arms were covered with it and patches also appeared upon the trunk.

About a year after his marriage Mrs. — was confined with a female child under my care; the labour was natural and easy and the mother recovered without developing any symptoms of syphilitic infection.

The infant appeared perfectly healthy and was suckled by its mother; it fed regularly, the motions were normal in colour and frequency, and it slept soundly. On the night of the fourteenth day after birth it refused the breast and was observed by the nurse to be drowsy and feeble; at 1 A.M. she found it cold, blue, and gasping for breath. When I arrived an hour later it was in a state of semi-collapse, dusky, pulse running and almost imperceptible, and so weak it could scarcely cry or move. The temperature was 99° 5'. It was ordered some brandy and a warm bath. Next morning a few mulberry-coloured spots were visible on the face, arms, and buttocks, which did not fade on pressure and were scarcely raised above the surface, but became as the day passed darker in colour and more prominent. Some fresh spots also appeared upon the legs. The temperature was now 102°; the child had been sick several times and the motions were somewhat slimy; otherwise the child appeared better; the pulse was stronger and skin less dusky. Suspecting that the child might be suffering from variola, it was weaned and separated from the mother for the next three days. The child rapidly improved in its condition, but the spots, about ten in number, grew hard, raised, and black, much resembling the spots of hæmorrhagic variola. In about three days time it appeared quite well, the spots remaining as before.

On the fifth day after the first attack it was seized in the same way again. It became rigid, cold, dusky, the respirations became gasping, and, according to its nurse, "it seemed convulsed." When I saw it about an hour afterwards it had partially recovered; the heart sounds were normal and so was the temperature. It fed as usual and the motions were healthy. It was ordered bromide of potassium and ammonia together with a little brandy at short intervals. In the night it had two or three similar attacks followed by much larger extravasations of blood beneath the skin. The next morning it was much weaker; it could scarcely cry, and did not take notice of anything about it, although it continued to take its food regularly and the motions remained healthy. The subcutaneous extravasations, three or four in number, took the form of bluish rounded lumps about one and a half inches in diameter, and there were also some small petechiæ upon the legs and buttocks.

From this time the child gradually sank; cerebral respiration supervened, and it died on the fourth day of the second attack.

No post-mortem examination was made. The child was never treated mercurially because the syphilitic character of the disease was not suspected, partly owing to my not being aware at the time of the father's previous history, nor of the existence of his skin affection, and partly to my ignorance of

¹ Careful examination of the heart elicited no signs of disease whatever.

this form of congenital syphilis. On ascertaining the father's condition I came to the conclusion that the symptoms were due to inherited syphilitic virus, but on turning to the literature of the subject at my disposal I failed to find such a case described by any English author. Lewis Smith, in "Diseases of Infancy and Childhood," speaks of hæmorrhage (especially umbilical hæmorrhages after separation of the cord), ecchymosis, and petechiæ as sometimes due to inherited syphilis.

Dr. West mentions a case of convulsions followed by melæna, but a specific cause is not hinted at. In no other work can I find mention of a case of purpura and subcutaneous hæmorrhages in the newly born except as resulting from infection by one of the eruptive fevers, under which category this case could not possibly be placed. I should add that I could obtain no history of hæmophilia in either the father's or the mother's family. The father has been placed under the influence of camomel baths for nearly a month, and the rash is disappearing.

P.S. Since the above was written, eight months ago, the father has completely recovered from his skin affection, and there has been no further return of it. A somewhat similar case is mentioned by Lanceraux in his "Treatise on Syphilis," vol. ii., p. 156 (New Sydenham Society). Effusions of blood into the serous cavities are mentioned by Hutchinson, Baresprung, and others, as the result of inherited syphilitic virus.

Albion-street, Hyde-park.

CASES IN SURGERY.

By T. HUGHES, M.D.,

SURGEON TO THE DINORWIC QUARRIES HOSPITAL, LLANBERIS.

STRANGULATED INGUINAL HERNIÆ.

As this case presents a certain amount of interest, I venture to publish the following notes:—

J. H—, aged eighty years, subject to double inguinal herniæ for several years. Never having worn a truss he had always been able to reduce both herniæ. On Wednesday, September 15th, he was attacked with violent pain in the left hernial tumour. He made several fruitless attempts at reduction. On the following day he sent for a medical man, who also failed to return the hernia. On Friday, the 17th, I was sent for, when I found the patient in the following condition. He had all the symptoms of strangulation—pain, vomiting, and obstruction of the bowels. The hernial tumour was of moderate size and tender to the touch; the skin even inflamed. Under these circumstances I did not make any forcible or prolonged attempt at reduction with the taxis, suggesting that an operation be made without delay, to which the old man objected. His advanced age, the unfavourable state of his general health, as well as the condition of the hernial tumour, did not encourage me to urge very strongly an operation. Explaining to him, however, that an operation was the only means of affording him any chance of recovery, after twenty-four hours' delay the patient consented. Having obtained the assistance of my excellent friend and neighbour Dr. Roberts, Clwtybont, I proceeded to operate in the usual way. The patient was placed under the influence of chloroform. The first incision was made by transfixion over the neck of the sac. The coverings were so adherent together as to render distinction impossible. When the bowel was reached it was found highly inflamed. The stricture was divided with some difficulty; the bowel was returned into the abdomen; the parts brought together by a few sutures, and the wound treated with the antiseptic dressing. There was some sanious discharge during the first two days; union by first intention; no suppuration (thanks to Listerism). The bowels acted spontaneously two days after the operation. The old man is now recovered and going about.

COMPLETE LATERAL DISLOCATION OF THE KNEE-JOINT.

A quarryman, working in the removal of some loose rock, having a rope fixed to his thigh, the rock to which the rope was fixed above gave way, causing the man to fall with a large quantity of rubbish to a depth of thirty yards. When extricated from his perilous position, it was found that there was hardly any part of his body free from injury, consisting

of extensive scalp wounds and fracture of nasal bones; the elbow-joint was also opened with extensive destruction of the soft parts, and fracture of the articular extremities of the bones entering into the formation of the joint. There were besides simple fracture of the left leg, a deep wound in the perineum, and a complete lateral dislocation of the knee-joint, so much so that the internal tuberosity of the tibia was resting on the lower part of the external condyle of the femur. The articulation of the tibia and femur had dissolved partnership; there was no loss of continuity of the skin, although so much on the stretch as to be nearly torn. I have consulted several surgical authors, and I find lateral dislocation of the knee spoken of as being "always partial." Under the circumstances, I think this case is worthy of record as a matter of clinical history. I need not say there was no difficulty in reducing the dislocation, as the ligaments must have been all ruptured. The poor man never recovered from the shock, and death put an end to his sufferings within twenty-four hours.

Llanberis.

WESTMINSTER HOSPITAL.

ILIAC ABSCESS TREATED ANTISEPTICALLY; CURE.

(Under the care of Mr. PEARCE GOULD.)

FOR the following notes we are indebted to Mr. Chas. Rooke, dresser.

H. L—, aged thirty-two, was admitted into Chadwick ward on Sept. 1st, 1880. She stated that when twelve years of age she suffered from abscesses over the right hip and ankle, and below the right angle of the lower jaw, where there was a depressed scar. She was married in 1873, and had had seven children, five of whom had died, two from hydrocephalus; the two living children she said were healthy. She was delivered of the seventh child early in June, and was four days in labour; the lochia ceased in three days, and a fortnight after she had a profuse purulent discharge which lasted a month. During the last month of her pregnancy the left leg was swollen and the veins big, but these symptoms left her after delivery. When she began to get about after her confinement she felt pain in her left hip, which she found was stiff. Soon after she noticed a swelling in the groin, and another above Poupart's ligament. These swellings, and the pain, stiffness, and weakness increased, and she then sought admission to the hospital.

On admission she was pale, very emaciated and weak. The pulse was small, compressible, 120-140; temp. 102.2°. The skin was perspiring, and there were profuse sweats at night. The tongue was moist, and covered with a thin white fur, the appetite fair, bowels loose, two or three and sometimes more loose motions a day. The left hip was flexed to a right angle and adducted; and any attempt at moving the thigh caused great pain. A large fluctuating swelling presented above Poupart's ligament, over which the skin was thin. There were two smaller swellings below the fold of the groin, one to the outer side of the femoral vessels, the other quite at the inner border of the limb; they fluctuated and evidently communicated, and could both be emptied into the belly by gentle prolonged pressure. There was no œdema of limb.

The skin around was well washed in carbolic lotion (5 per cent.), and an incision was made into the two lower pouches of the abscess under the carbolic spray; more than a quart of pus escaped, and when the iliac pouch was emptied by pressure, and the hand removed, air was sucked in. With his finger Mr. Gould made the communication between the inguinal and iliac pouches free, and passed in a drainage-tube; the usual carbolic gauze dressing was applied with a large oakum pad outside it. The dressing had to be removed the same evening.

Next day (September 4th) the dressing was changed twice, and a little thin sero-purulent discharge mixed with air was pressed out. A folded towel was placed over the iliac fossa and firmly bandaged on to keep the walls of the sac in apposition as far as possible. One-two-hundredth of a grain of atropia was ordered to be injected hypodermically every night to check the sweating. The appetite was improved, and the patient was placed on full diet with two bottles of stout a day.

The dressing was changed on Sept. 5th, and once a day up to the 11th, and then every two days. The discharge was turbid serum, odourless, and daily diminished in quantity. The drainage tube was shortened from time to time, and removed on Sept. 17th, the wound was quite closed on Sept. 30th, and the patient left the hospital on Oct. 3rd.

Her improvement after the opening of the abscess, without a single intermission, was very rapid, and on her discharge she had picked up flesh, and looked strong and well. The opening on the inner side of the groin made it rather more than usually difficult to keep the parts aseptic, and necessitated a more frequent change of dressings than would have been otherwise required. The dressing was greatly expedited and simplified by an elevator, the invention and present to the hospital of Mr. F. C. Sheppard, a member of the house-committee of the hospital.

The temperature, which was persistently pyrexial before the abscess was opened, quickly fell, and reached 98° F. on the morning of Sept. 5th, and never again touched 99°.

Remarks.—This puerperal iliac abscess must not be confounded with others resulting from caries of the spine or ilium, but its progress illustrates well the results obtained by Listerism in the treatment of large chronic abscesses. The daily constitutional improvement, absence of fever, and entire cessation of the secretion of pus when the cavity was well emptied, are the results that Mr. Lister has taught us to expect when his treatment is carefully carried out, even though air be freely admitted. Two other points are worthy of note—one is the necessity for securing a free opening into the abdominal pouch of the abscess, the track under Poupart's ligament is often very narrow, and an incision in the thigh then fails to drain the upper larger sac of the abscess, whether it be psoas or iliac; the other is the advantage derived from pressure applied to keep the walls of a large abscess in accurate apposition and immovable.

SOUTH STAFFORDSHIRE HOSPITAL, WOLVERHAMPTON.

SCIRRHUS OF THE PERINEUM, WITH CANCEROUS INFILTRATION OF THE SUBPERITONEAL GLANDS.

(Under the care of Mr. KOUGH.)

FOR the following notes we are indebted to Mr. W. H. T. Winter.

Isaac J—, aged seventeen, was admitted into the hospital on August 13th, 1880, with a tumour of the perineum. His attention had first been directed to it in June, when he had experienced pain while straddling across a bar. The tumour was then about the size of a walnut; it caused him no inconvenience, except in the sitting position, and there was no history of injury. He had noticed that micturition was not natural. At times the urine would come in a fair stream, and then again it would only pass drop by drop. Defecation up to the time of admission was natural, and was unattended by pain. The boy said that during the past month he had lost flesh, that his appetite had fallen off, and that he was sometimes kept awake by aching pains in the perineum. Before the present illness he had been a robust boy, proud of his physical strength, and an adept at athletic exercises.

An indefinite history was obtained of some wasting disease in the father's family.

On admission a tumour of stony hardness was felt in the perineum. It was nodulated, and its imperfect mobility gave the idea that it was bound down by a dense fascia. It was as large as a pear, and extended from the front of the anus to beneath the pubic arch, so that its front part occupied the back of the scrotum. Laterally it extended from one tuber ischii to the other, but nowhere did it seem to be in absolute contact with bone. On trying to pass a silver

catheter the point diverged to the right before it got to the membranous portion of the urethra, and it could not be got any further by manipulation. A bulb-pointed elastic catheter passed, however, with ease. Examining the growth through the rectum, a hard, brawny substance was felt anteriorly, extending for about an inch and a half along the front of the gut. Beyond this the trigone of the bladder was distinctly made out. A catheter could not be felt per rectum till it passed the prostatic portion of the urethra. No enlarged pelvic glands were made out. The glands in both groins were enlarged and hard. In the hypogastrium, inclining rather to the right side, was a tumour about the size of an orange apparently in the abdominal walls. It was fairly definite on palpation, firm, and somewhat movable. The scrotum was cedematous. Both testicles and spermatic cords felt normal. The right lower extremity was considerably larger than its fellow, the right thigh being seven inches and a half thicker in circumference than the left. The right thigh gave a brawny feel and the skin over the front of it was spotted by numerous small extravasations round the hair-follicles. The patient's appearance was somewhat waxy. The sclerotics were brilliant and the gums pale. The body was fairly nourished, the appetite was moderate, and there was no thirst. The urine varied in sp. gr. from 1010 to 1015, and contained a trace of albumen; it was acid on being passed but soon became alkaline. After his admission the patient felt pain in the hypogastrium during defecation. The pulse was soft and regular, the temperature and respiration were normal, there were no night sweats, and the patient complained merely of lassitude. On Aug. 18th the patient had some epistaxis. It came on at intervals on the 19th and 20th. On the 23rd the evening temperature was 103° 5' and the pulse 120. He had some epistaxis during the night and slept badly. On the 24th he looked waxy-pale. He had vomited a brownish fluid and felt very ill. The respiration was hurried; pulse 120; temperature 102°. The temperature in the evening fell to 99°, the radial pulse became imperceptible, the patient threw his arms about restlessly, and in a short time died.

A post-mortem examination was made by Dr. Hunt twenty-four hours after death. On opening the pericardium the heart was found thickly dotted with small petechiæ. It was normal, and weighed nine ounces. There were also petechiæ over both lungs. The left pleura contained about six ounces of blood-stained fluid. Both lungs were healthy, and there were no adhesions. On opening the abdomen the intestines were found to be congested, and there was some blood-stained fluid in the peritoneum. The viscera being removed, a row of extravasations was seen beneath the parietal peritoneum along either side of the spine, and there was a large effusion of blood over the sacrum. The lymphatics in the pelvis and along the spine were enlarged, hard, and nodulated. There was a mass of lymphatics on the right side of the pelvis as large as an orange. An incision was made along the right side of the scrotum, and the perineal growth dissected out, together with the urethra, bladder, and rectum. The growth was four and a half inches long, three broad, and two and a half inches in thickness. The greater part of its upper surface was beneath the urethra, and its posterior border lay in contact with the levator ani; it involved neither the urethra, the testicles, nor the gut. It was of stony hardness; its surface was nodulated, and it cut with a cartilaginous section. The cut surfaces became cupped, and, on scraping, they yielded but very little juice. There were hæmorrhages into the substance of the growth, as there were into the infiltrated glands into the pelvis. The tumour into the abdominal walls was found to occupy the lower quarter of the right rectus. It was hard and gristly, like the perineal growth, and muscle fibres ran in its substance. The bladder contained some urine, and on opening it one spot of extravasation was found on its posterior surface. The vesiculæ seminales and Cowper's glands were healthy. The kidneys were somewhat pale, especially the pyramids. There were no emboli or petechiæ. The capsules were not adherent. The right kidney weighed six ounces, and the left five ounces.

Mr. Terry has kindly examined the growth microscopically. He says it is a carcinoma of a scirrhous type. There were dense fibrous alveoli, containing epithelioid cells. In the central part of the tumour the fibrous tissue was predominant, the alveoli being shrunken, and containing some few epithelial cells.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Hydatids of the Liver treated by Abdominal Section and Drainage. — Hyperpyrexia after "Listerian Ovariectomy."

THE ordinary meeting of this Society was held on the 14th inst., J. E. Erichsen, Esq., F.R.S., President, in the chair. It was remarkable for one of the most animated debates upon "Listerism" that has yet occurred in the Society, in which, however, time allowed but few to join, although the meeting was prolonged to a late hour. Dr. Bantock's paper, attributing many of the evil consequences, and especially the fever of ovariectomy, to the toxic effects of carbolic acid, was the means of evoking this discussion, Mr. Thornton and Mr. Spencer Wells supporting Listerism, and Mr. Lawson Tait, Mr. Savory, and Mr. Holmes speaking against the method and the theory on which it is based.

A paper was read on a case of Hydatids of the Liver treated by Abdominal Section and Drainage by Mr. LAWSON TAIT, F.R.C.S., of which the following is an abstract. Mr. Lawson Tait gave the details of a case of hydatids of the liver, in which he had performed abdominal section successfully. The patient was a lady, aged thirty-seven, under the care of Dr. Pike of Malton, with whom Mr. Tait saw her in consultation in August last. The diagnosis of hydatids had been made by Dr. Pike, and confirmed by Sir Wm. Jenner, who saw the patient a few days before Mr. Tait did. The tumour was of immense size, the hepatic dulness reaching from the third rib to the level of the umbilicus, and crossing the middle line. No air seemed to enter the right lung, and the patient's breathing was greatly interfered with. There was incessant vomiting, and great exhaustion. The disease seemed to date from 1872, but the history up till February, 1880, was not clear. Mr. Tait opened the abdomen above and a little to the left of the umbilicus, and found the liver tissue quite healthy in appearance, and not adherent to the abdominal wall at any spot. He made an incision into the liver about three inches long, and evacuated about two gallons of hydatid cysts, varying in size from a pea to an orange. The liver tissue at that spot was about half an inch thick. He then stitched the edge of the wound in the liver to the edge of the wound in the abdominal wall, and fastened in a wide glass drainage-tube eight inches long. The relief to the patient was immediate and complete. The cavity rapidly contracted, continuing to discharge cysts and pus, tinged with bile, for about eight weeks. She rapidly gained appetite and flesh, having now, ten weeks after the operation, only a small sinus remaining.—Dr. JOHN HARLEY urged the practice of free incision and evacuation of the contents of hydatid cysts in preference to the use of the aspirator or simple puncture, believing that in the latter case the cysts often subsequently enlarged.—Dr. ALTHAUS alluded to the means obtained by Mr. Durham in the electrolysis of hydatids, and thought the procedure was worthy of more frequent adoption. It was based on the theory that caustic soda was liberated by the current, and killed the parasite.—Mr. HULKE congratulated Mr. Tait on the issue of his case. He had no doubt of the cure of several cases of non-suppurating hydatids by simple puncture and evacuation of the fluid, and believed the good effects of electrolysis largely due to leakage of the fluid. Inflamed and suppurating cysts must of course be treated by free incision.—Mr. SPENCER WELLS also had seen hydatid cysts cured by simple puncture, and quite lately had removed as much as eighty pints of fluid from one.—Mr. HUTCHINSON had published cases of effectual cure by puncture several years ago, and had many similar cases since. The procedure adopted by Mr. Tait, although formidable, was justifiable in the case being one of unusual kind.—Mr. THORNTON had under treatment a patient who had been previously aspirated, and he proposed before making a free incision to endeavour to procure adhesion between the liver and parietes.—Mr. WILLETT asked Mr. Tait if the wound was

kept perfectly aseptic throughout.—Mr. LAWSON TAIT, in reply, said that no antiseptics were used; only absorbent wool and zinc lotion. The case was of that variety where the mother cyst was packed with scolices, differing from those cases where there was much fluid. Simple tapping was out of the question; indeed, aspiration had been performed two weeks before, and the patient had become rapidly worse.

Then followed a paper on "Hyperpyrexia after Listerian Ovariectomy," by Dr. GEORGE GRANVILLE BANTOCK, of which the following is an abstract:—Mr. Lawson Tait had already questioned, before the Society, the advantages attributed to the Listerian precautions in the operation of ovariectomy. The absence of pyrexia has been claimed as one of the best results following such precautions. In this paper the fact that pyrexia is absent in cases treated antiseptically is disputed on clinical evidence. In the author's own experience, the Listerian method in a series of thirty-six cases shows in its favour a difference of but 0.4°, compared with the same number of cases undertaken without complete antiseptic precautions; the very lowest temperature occurred after a non-Listerian ovariectomy. Volkmann admits a condition of poisoning from absorption of carbolic acid, and terms this accident "aseptic fever." Thiersch has encountered instances of great irritation from this agent, and now employs salicylic acid in its stead. Keith finds very little difference in the temperature of series of cases undertaken under the old and the new method. In three Listerian cases the temperatures were the highest he had ever seen. Before adopting antiseptics he never found the ice-cap necessary for the reduction of pyrexia, excepting in one acute case of septicæmia. On the other hand, Mr. MacCormac asserts that the rise of temperature in Listerian cases is slight, or absent, and when present is due to other causes; Mr. Spencer Wells has found that, contrary to Mr. Tait's experience, pyrexia is subdued by antiseptics. Mr. Thornton has observed no fever at all, as a rule, after antiseptic ovariectomy. When, however, an operator is disposed to support Listerism, he may readily attribute to other influences ill results, of which it alone can be the cause. It is easy to explain how pyrexia follows "antiseptic operations." Carbolic acid is an irritant; its great advocate introduced the "protective" to counteract its irritating qualities. It is also a poison. It has caused death when inhaled, and has produced very serious symptoms when absorbed; this is illustrated in cases related by Lister, Lightfoot, Hanhorst, and the author, who describes at length two cases of poisoning from prolonged action of carbolic spray in complicated ovariectomies. In both the kidneys were affected by this medium. Agostini relates a case of poisoning from carbolic acid solution injected frequently into an abscess cavity. Thomas Smith and others have noted the bad effects of this acid in operations upon children. The author observed albuminuria and temporary suppression of excretion of sulphates in the urine of a young girl after antiseptic ovariectomy. Sonnenburg, Lightfoot, and others have also found that sulphates disappeared from the urine in similar cases, whereas in the author's patient that excretion did not become dark. Hence carbolic poisoning is not always indicated and exposed by discoloration of the urine, as is generally believed. Keith admits that evil effects may result from prolonged action of spray. The hyperpyrexia which follows is due not solely to reaction, but also to carbolic intoxication. The whole merit of Listerism lies, not in the supposed good effects of carbolic acid, but in the cleanliness which it promotes. By greatly reducing the strength of the solutions used in operations, the author has gained excellent results with absence of pyrexia.—The PRESIDENT remarked upon the local anæsthetic effect produced by the carbolic spray. It produced a numbness of the hands, and he thought this showed that the carbolic acid had some action on the peripheral nerves.—Mr. KNOWSLEY THORNTON said, that no one had claimed that Listerism was never followed by pyrexia, unless it were Mr. Tait himself, who, in his paper published in the recent volume of the Transactions, says (page 133): "As the temperature and pulse-curve are uniformly admitted to represent the course of any case involving febrile action, if the antiseptic system makes its claims justly, ovariectomies performed under its precautions ought to indicate a more even and less febrile course of recovery than the non-antiseptic cases, and this should occur independently of all other details of the operation." Obviously more fever must follow a difficult operation than a simple one. In the debate on that paper Mr. Holmes remarked that the whole question was one of "impressions," and he (Mr. Thornton)

resolved now to state facts; and to contrast the temperatures of non-antiseptic and antiseptic ovariectomy. Of the former he had had twenty-five successful cases with an average stay in hospital after operation of 26·3 days, and of the latter 150 successful cases with an average stay of 20·5 days. In twenty-five non-antiseptic cases the ice-water cap was used seventeen times, or in 68 per cent.; in 150 antiseptic it was used thirty-one times, or 20 per cent. It was used to reduce temperature in twelve non-antiseptic cases, or 48 per cent., and in fourteen antiseptic cases, or 9 per cent. On this point he saw from a letter from Dr. Bantock in the *Medical Times* that he agreed with him. In the remaining cases the cap was put on to prevent high temperature—viz., 20 per cent. of the non-antiseptic cases, and in 11 per cent. of the antiseptic cases; but of late he had limited its use to the reduction of temperature only. In the non-antiseptic series the temperature never rose above 100·4°—i.e., there was no fever in but two cases, or 8 per cent.; in the antiseptic—forty-five cases, or 30 per cent.; and if the cases in which there was a slight additional rise of 1° or 2° for a few hours be included, the figures would be 32 per cent. of the non-antiseptic series, as against 75 per cent. of the antiseptic recovering without fever. Dr. Bantock should not have styled his cases as Listerian ovariectomies at all, and the number (thirty-six) was too small to draw such large inferences as he had done. Although he himself had practised antiseptic ovariectomy in 200 cases, he felt he had yet much to learn in the application of the method, and he generally found that when a case went wrong some detail had been omitted. In his last 100 cases, with a mortality of 7 per cent., three patients died from septicæmia, a result which he was sure would not have occurred had he thoroughly acted up to the theory of Listerism, and in Dr. Bantock's cases the drainage-tubes were often changed by the nurses during the night, a practice certainly *not* that of Listerism. Recently Dr. Bantock had (in THE LANCET) published statements of practice which he styled Listerism, but which only proved that he was not in a position to carry out that practice, so contrary were they to Lister's express teaching. The occurrence of nephritis could not be attributed to carbolic acid poisoning, for long before antiseptics were introduced into ovariectomy deaths occurred from suppression of urine, &c., and quite lately he had such a case, in which death took place within twenty-four hours after the removal of a tumour weighing 88 lb., there being chronic Bright's disease. Septicæmia, too, was often fatal from failure of the kidneys to act, and comparison of the post-mortem records of such cases before the days of antiseptics showed no difference in the lesions observed in them and in those cases attributed to poisoning by carbolic acid. A German surgeon had recently said that in his country they had become so convinced that septicæmia had been banished by Listerism that deaths formerly attributed to this cause were put down to the toxic effects of carbolic acid. It was one thing to use the method and another to act up to Lister's practice and theory, and it would be far better if those who did not accept the theory would cease to practise the method, since their failures were no proof of the falsity of the theory. When studying under Professor Lister, at Edinburgh, he had repeatedly seen the urine darkened by carbolic acid without any other effects. He failed to see on what principle Dr. Bantock used a 1 per cent. solution of the acid, which Dr. Bantock said was no longer germicide. If so, why trouble to introduce this 1 per cent. of an "irritant" and a "poison"? Was it done to increase the cleanliness of the water? Dr. Bantock's results at the Samaritan Hospital were the same as those obtained by Mr. Spencer Wells without antiseptics at all, and using chiefly the extra-peritoneal method. Mr. Tait says that the advantages claimed for Listerism are really due to the adoption of the intra-peritoneal method. But was this so? He had compared the statistics of the Samaritan Hospital for periods of six years with this result. Mr. Spencer Wells, from 1872 to 1877 inclusive, had 191 cases (extra-peritoneal) with a mortality of 20 per cent.; Dr. Bantock, from 1875 to 1880, inclusive, had 136 cases (intra-peritoneal and modified antiseptics) with a mortality of 17·64 per cent. Mr. Thornton in the same period had 181 cases (intra-peritoneal and antiseptics), with a mortality of 11·6 per cent. These differences were due to the more thorough use of the antiseptic method. In the present year, Dr. Bantock, using his *very modified* antiseptic method had had forty cases with a mortality of 12 per cent.; Mr. Thornton, with pure Listerism, had fifty-four cases with a mortality of 7·4 per cent., including two deaths from septicæmia,

which he attributed to failure in carrying out the method. Still, Mr. Wells in the last two years of his hospital practice had only a mortality of 10 per cent. in intra-peritoneal cases, a result largely due to the use of the ice-cap and drainage. In his own last 100 cases, Mr. Thornton had a mortality of 7 per cent., twenty-seven of these being private cases, with one death—a case of unusual difficulty. All this went to prove that with every case the mortality without Listerism could not get below 10 per cent.; and if by the adoption of the method the mortality could be lowered by three or four per cent., that end was alone worth the extra trouble and difficulty entailed by the method.—Mr. LAWSON TAIT was surprised that Mr. Thornton should have quoted the passage from his paper in the sense he did, and regretted that there did not seem to be a clear understanding as to the meaning of Listerism; since it had just been stated that it was no part of the Listerian theory to avert septic fever. Hitherto he had thought that the whole aim of the theory was to eliminate this surgical fever after operations. If this were not its aim, what was it? In fatal cases of ovariectomy the temperature rises steadily to the end. He could not then concur in any of Mr. Thornton's remarks. As to the duration of stay in hospital, there was a great difference between cases in which the clamp was used and those in which it was not.—Mr. THORNTON said he had excluded all clamp cases from this reckoning.—Mr. TAIT, proceeding, said that he had a series of 137 abdominal sections, in which 48 were done with *extreme* Listerian precautions, and the remainder successively by the elimination, one after another, of these precautions; so that after reducing the strength of the carbolic spray to 1 in 150, he had finally conducted the whole of the process under a spray of water alone! And so far as the temperature went, it had diminished in proportion as the amount of carbolic acid was lowered. In the 48 pure Listerian cases there were 5 deaths; in the 91 "modified" cases, 6 deaths; and he did not know if any better result could be obtained than that. With Listerian precautions the wounds never heal by first intention, but always with formation of pus; and Dr. Savage, who practises Listerism, remarked that in his cases the wounds did not heal so well as Mr. Tait's without it. Mr. Tait had had one case in a young woman, from whom he had removed both ovaries—no adhesions—in which the temperature rose to 112°, and remained at that height for forty-eight hours. She recovered perfectly, and there was nothing in the case but carbolic acid poisoning to account for the remarkable rise in temperature. The ice-cap could not be cited as a criterion; he himself had never used it. He once used Dr. Richardson's "collar," invented many years ago; but the case proved fatal, and he never used it again. Success depended more on personal care and experience than on anything else. Mr. Thornton had had the great advantage of being associated for many years with Mr. Spencer Wells, and this must be taken into account in comparing his statistics with those of others. He (Mr. Tait) lost nineteen out of his first fifty cases, and he did not think he would have had such a mortality had he had the opportunity of seeing, and assisting at, the operations of so distinguished a master.

The usual hour for adjournment having arrived, it was resolved to continue the debate.

Mr. DORAN having examined after death forty-one cases of ovariectomy, found that the kidneys were normal in only seven, and in one of that number death was due to tetanus, in another to pleurisy. Of the renal disease six were cases of dilatation of ureter and pelvis on one side. The rest exhibited various degrees of subacute and chronic Bright's disease. In many cases there were lesions of other viscera, mostly diagnosed before operation; but the renal disease was nearly always latent; and this fact should be borne in mind before pronouncing on the statistical results of operations by different methods; and until it became possible to ascertain the existence of such disease there must always be room for fallacy in the comparison of such statistics. Albuminuria alone would not contra-indicate operation, for it might be due to pressure, which the operation would relieve. Diminution in the quantity of urea might be due to diminished quantity of food; and sometimes in renal disease there was an excess of urea. Dr. Bantock had remarked upon the diminution of the sulphates as evidence of carbolic acid poisoning. Dr. Parkes has shown that thirty-one grains of sulphuric acid are eliminated by the kidneys in twenty-four hours. After a severe operation the call on the kidneys must be very great, and if they be diseased

great risk was added to the patient's chances of recovery.—Mr. SAVORY said that the only point on which there seemed to be agreement, was that as experience increased the mortality diminished. He asked if this did not point to the question being one of the man rather than the method; and did not such a reflection vitiate all conclusions derived from statistics of the first twenty cases compared with the second twenty, and so on?—Mr. SPENCER WELLS would meet Mr. Savory's argument by the experience of the same surgeon in a successive series of years. No doubt the mortality diminished with increasing experience, but after a time the mortality reaches a level below which it will not fall, until the introduction of a new method leads to further improvement in the results. It had so happened with him. At first the mortality gradually fell from 34 per cent. to 28, to 24, and so on, until it reached a level beyond which it did not fall, and the question came whether it was possible to reduce the mortality still lower. This caused him to adopt the antiseptic treatment, and at the beginning of 1878 he commenced to follow Listerian methods. To be sure, the cases in which he applied it were all in private patients, but he had when in hospital practice found no difference in the results of the two classes of patients; nor was it due to the intra-peritoneal method, for before he used antiseptics he had been less successful with this than with the intra-peritoneal. Since adopting Listerism he had had 131 cases, with 13 deaths—a mortality of 10 per cent.; which was precisely the same mortality he had in the last two years of his hospital practice—viz., 7 deaths in 71 cases. These figures alone might be quoted to show there was no advantage gained by Listerism. But there were very real advantages. He was surprised to hear Dr. Bantock, Mr. Tait, and Mr. Thornton find such rises in temperature after Listerian ovariectomies, for he never saw them; it was rare to see the temperature over 100°. The method did not involve trouble—it greatly saved it. Formerly a case had to be closely and personally supervised; but all this trouble and anxiety were saved in treating a case antiseptically. Again, in forty-nine cases out of fifty so treated the wounds heal by first intention; and it was quite a matter of surprise to him to find, as he did lately in a case, any pus in the wound. In that case its appearance was explained by the development of boils in other parts of the body.—In reply to Mr. Tait, Mr. WELLS added that when the pedicle was short he used the ligature in preference to the clamp.—Mr. HOLMES said that after all they had heard that evening from the advocates and opponents of Listerism he was ready to withdraw his former observation that the grounds urged in favour of the method were based only on "impressions"; and he would like to put it to the Society, whether, after these definite details, there were such characteristic differences between cases treated with and without the method, as would be the case were its theory true. Recalling the claims urged for the theory when it was first promulgated, he would ask whether it was at that time thought in 130 cases treated under the theory would show the same result as those treated otherwise? Whether, if one was not told, one would perceive any real essential difference between the cases which were treated on the basis of the germ theory and those without this basis? He was not a partisan of any one method. He had sat at the feet of Lister, and had tried to master the details of his method, which in the early days were far simpler than at present, for they had been so modified that he confessed he did not understand them; and he was sure Mr. Thornton did not understand them, since he attributes his fatal cases to a lack of mastery of these details. Did Mr. Lister himself even understand them? Was the theory itself understandable? When a case is lost, the failure is put down to failure to understand the theory; when a case is saved, then the theory is triumphant. If this were all it came to, and after the method had been so long in use there was still a quarrel as to its advantage in 1 per cent. of the cases, it might fairly be said that the theory was "not proven."—Dr. BANTOCK, in reply, said that the local anæsthesia produced by carbolic acid was well known to him. He quoted from a paper written by Mr. Thornton to show that that gentleman attributed two deaths from pleurisy to the chilling produced by the spray, and one from suppression of urine to the carbolic acid; and in another paper spoke of extreme congestion of the kidneys as due to carbolic acid. In his own practice he had treated thirty-six cases with true Listerian precautions, with eight deaths, one patient dying on the operating table. With a

solution of carbolic acid, 1 in 50, he had treated forty-one cases with a mortality of three, one of these cases was *in extremis* when operated on; another died from acute nephritis, and a third from tetanus, on the eighth day, and apparently independently of the operation. In two of these cases he had used the ice-cap, and he found that in proportion as the strength of the solution was reduced to 1 in 60, 1 in 80, to 1 in 100, the results improved, the ice-cap never being required since he had used the weaker solution. He had had many cases in which there was disease of the kidneys—a most unfavourable condition, owing to the little or no power of elimination. He quoted recent statistics of an Italian surgeon, showing that in his practice ovariectomy with Listerism in 100 cases gave a mortality of 37 per cent., and in a second series of 100 cases without Listerism a mortality of 36 per cent. Mr. Bryant had recently published facts showing that pyrexia in surgical cases was considerably less than supposed, without undue antiseptic precautions being taken. Mr. Spencer Wells had stated in his book that he never used the ligature when the clamp could be used, and it was not therefore surprising that the ligature should compare unfavourably with the clamp. The merit of using a solution of carbolic acid of 1 per cent. strength lay in its not causing hyperpyrexia; he had not once to use the ice-cap in cases treated with this solution, and out of twenty-nine cases had lost eight, two deaths being from shock. The great point was strict attention to cleanliness, and in this respect the modern practice differed from that formerly in vogue. Mr. Heath was the first to put this principle into practice, and, combined with free drainage, found that Listerism did not add to the measures, although it added to the risk of subsequent pyrexia. The dread of injuring the peritoneum had disappeared before Listerism was taught, for it was shown that fever decreased in proportion as effectual drainage was practised, and the causes of irritation of the peritoneum avoided. Patients still died even under the strictest Listerism. He would not follow Galezowski, who said that since he had used antiseptics (!)—viz., solution of carbolic acid of 1 in 1000—his operations on the eye were markedly successful; and, whilst according full measure of praise to Mr. Lister's teaching, he could not admit the truth of those exaggerated pretensions claimed for his method by his disciples with a zeal which outran discretion.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Retarded Signs in Pneumonia.—Left Hemiplegia, with Aphasia.—Radical Cure of Web-fingers.—Removal of Villous Growth from Bladder.

THE ordinary meeting of this Society was held on the 10th inst., Dr. E. H. Greenhow, F.R.S., President, in the chair. A paper by Mr. Tyson, calling attention to the frequency with which the physical signs are retarded in acute pneumonia, received confirmatory support by several speakers. A pendant to the interesting case of lesion of Broca's convolution, without aphasia, in a left-handed subject, read by Dr. Taylor at the last meeting, was afforded in a case related by Dr. Habershon, of destruction of the right frontal lobe, with aphasia, also in a left-handed subject; and elicited some suggestive remarks from Dr. Hughlings Jackson. Mr. Davies-Colley related a case of successful removal of villous growth from the bladder, probably the first in which cystotomy has been performed in this disease. A case of cross-legged progression was shown by Mr. Tyson.

Mr. TYSON (of Folkestone) read notes of cases of Acute Pneumonia, in which the usual physical signs of the disease appeared late in the case.—Case 1. A man, aged sixty-four, caught cold whilst driving on April 4th, 1880, and next day was compelled to give up work. He was seen for the first time on the 8th, when he complained of pain in the chest, and expectorated some tenacious mucus. There were no abnormal physical signs. Temperature 103; pulse 88; respiration 30; urine albuminous. On the 11th slight dulness appeared at the base of the left lung; fever was high. On the 12th (eight days after the chill) there was well-marked dulness,

bronchial breathing, and bronchophony. He was very feeble, and died on the 15th.—Case 2. A female, aged twenty-five, in Guy's Hospital under the care of Dr. Pye-Smith, taken ill three days before admission, when the temperature was 104°. Signs of pneumonic consolidation appeared on the sixth day, and death took place on the seventh. There was grey hepatisation of the right upper lobe.—Case 3. A male, aged fifty, in whom no dulness was discovered till the sixth day. Death occurred on the tenth day. In two other cases Mr. Tyson had marked the absence of physical signs until the fifth day. He referred to the statement made by Dr. Bowles, that in asthmatical subjects attacked with pneumonia dulness often did not develop till four or five days after the seizure. After quoting passages from Ziemssen's *Cyclopædia* and Trouseau's lectures to show that such a late development of physical signs was not generally acknowledged, he concluded by stating that this retardation of signs occurred more frequently than was generally supposed, and might be attributed to the central parts of the lung being primarily affected. In such cases the onset of the attack, the pyrexia, and the altered pulse-respiration ratio should be relied on as diagnostic points.—Dr. F. TAYLOR confirmed the author's statement as to the relative frequency with which the physical signs appeared late in the disease, and quoted a case which came to the out-patient department with a history pointing to pneumonia. The physical signs were not apparent, although it was about the fourth day; but the patient coughed up some rusty sputa and was admitted. Soon afterwards physical signs became developed. In another case the delayed signs appeared before the rusty expectoration.—Dr. ANDREW CLARK said the paper was an important contribution to the literature of the subject, for anomalous and capricious cases of pneumonia were imperfectly recorded; but he did not think it added much to the knowledge of experienced men. He was constantly meeting with cases in which the constitutional evidence of pneumonia long preceded the appearance of local signs. He would mention three such cases. One was a case of a gentleman he saw in consultation with Dr. Stephen. After a slight rigor the temperature rose to 101°, and for seven days there was no evidence of the disease, except the general distress, rapid breathing, and altered pulse-respiration ratio. The physical signs of pneumonia appeared on the eighth day. Another case was that of a gentleman, aged eighty, at Southsea, seen with Mr. Potts and Sir W. Gull. After a chill there was a period of ten days marked by irregular pyrexia, malaise, and hurried breathing. On the eleventh and twelfth day slight friction was heard below the angle of the right scapula, followed by dulness and tubular breathing. The patient recovered. A third case was one he saw with Dr. Buzzard, when the patient had been ill for six days with pyrexia without any local signs. He did not think it necessary to have all the physical signs present to diagnose pneumonia; and that in cases of central pneumonia the disease was too far removed from the surface to yield these signs. With a history of chill, with distress and prostration, with fever, and a disturbed relation between pulse and respiration, one may be absolutely certain that the case is one of pneumonia.—Dr. HABERSHON concurred that in some cases the general symptoms, with hurried breathing and rusty expectoration, without physical signs, must be taken as sufficient for diagnosis. No doubt such anomalies were explained by the disease being deep-seated, so that the physical signs are obscured, just as a severe pleurisy may involve the surface of the diaphragm without any friction being audible. When the physical signs do become manifest the pneumonia has probably extended to the periphery.—Dr. ANDREW CLARK added that pneumonia might be diagnosed from the general conditions; because in a large number of cases there is neither cough, nor expectoration, nor pain in the side.—Dr. DE H. HALL, some five or six years ago, had recorded two cases of apical pneumonia marked by severe head symptoms. One was a man, aged nineteen, who was comatose for six hours; the other a child, who had repeated convulsions; and it was only on the fifth or sixth day that distinct tubular breathing appeared. One reason for the severity of these cases, as compared with those which ran a more typical course, might be found in the greater amount of lung involved in central than in peripheral pneumonia.—Dr. BURNLEY YEO said that such cases suggested the question whether the lung condition was not secondary to a constitutional disorder.—Dr. GOODHART observed that the question was a

complicated one, so many conditions occurring under which the physical signs varied. In old people the late appearance of these signs was attributable to the presence of emphysema. At the same time he agreed with Dr. Yeo that blood-poisoning might be the primary condition to which the pneumonia was secondary. Some years ago he examined the body of an old man, who died three or four days after taking a chill. There was only a slight amount of pneumonia, and the only interpretation he could put on the case was that the chill, arresting the function of the skin, had caused blood-poisoning, and that sufficient time had not elapsed for true pneumonia to be fully developed.—Mr. TYSON replied, that all his cases ultimately developed the signs of ordinary pneumonia. The last case he had seen was in a child, five years of age, with high temperature for six days, without pneumonic symptoms. He had written the paper because all the authorities he had consulted did not mention the proportion of cases in which this delay in the development of physical rigors occurs; although many state that they have seen such cases.

Dr. HABERSHON read a case of Aphasia, with Hemiplegia on the Left Side, and Tumour on the right side of the Brain in the third frontal convolution. The patient was a man, aged fifty-two, who had had symptoms of languor for a year before admission. Seven weeks previously he had a sudden difficulty with his speech; he tried to say something, and could not speak the right word. This got worse until three weeks ago, when weakness of the left arm and leg was noticed. On admission there was partial left hemiplegia; the pupils slightly contracted, urine free from albumen, bowels confined. His wife stated that he had always been left-handed. He was treated with iodide of potassium and mercury, but in a few days he became unconscious; and though he rallied for a short time and appeared to understand questions, he became restless, trying to get out of bed, then comatose, and died thirteen days after admission. At the post-mortem examination a gelatinous-looking lobulated tumour was found on the right side of the brain, occupying the region of the island of Reil, and involving much of the lower part of the third frontal convolution. It measured an inch or more on the surface, and extended two inches into the brain substance, so as to reach the lenticular nucleus of the corpus striatum. The section had an orange tint, with numerous ecchymoses, and at the margin some yellowish gelatinous material. It was composed almost entirely of small round lymph-like corpuscles, but in some parts showed nothing but compound granular corpuscles. There was broncho-pneumonia at both bases, and atheroma and calcareous change in the cardiac valves and aorta. The kidneys were rather granular. Dr. Habershon drew attention to the case as illustrating the view that the faculty of speech is associated in the brain with the muscular education of the most used arm, since the patient was left-handed, and suffered from aphasia, when a tumour developed in his right third frontal convolution. Some points in the history of his children seemed to indicate a syphilitic origin for his complaint, but the result showed that the tumour was a glioma.—Dr. F. TAYLOR reminded the Society of the main facts in the case reported by him at its last meeting, when there was embolic softening of the region supplied by the left Sylvian artery, without aphasia (see THE LANCET, Dec. 4th, 1880, p. 896), and when it was subsequently elicited that the child had been left-handed from birth in consequence of some deformity of the right arm. It would have been impossible to have detected any old lesion of the left hemisphere had it existed, owing to the disorganisation produced by the embolism.—Dr. HUGHLINGS JACKSON had observed several cases of aphasia with left hemiplegia, mostly in left-handed persons, and had recorded such a case recently (THE LANCET, April 24th, 1880). Aphasia from cerebral tumour was rare; it might occur by hæmorrhage in cases of vascular tumour. There was temporary aphasia after some epileptic seizures, usually those beginning on the right side, in cases of disease of the cortex cerebri. It was a significant thing that aphasia usually went with right hemiplegia, and the cases recorded by Dr. Taylor and Dr. Habershon were valuable as exceptions proving this rule. Dr. Hughlings Jackson thought, however, that the thing of most significance was that disease of but one side of the brain might destroy speech. There was another thing of quite equal significance—viz., that disease of no part of either side alone caused "wordlessness." At any rate, in most cases of complete aphasia, uncomplicated by hebetude, due to very extensive cerebral disease, the patient who could not speak

could understand what was said to him—proof positive that, although *speechless*, he was not *wordless*. Dr. Hughlings Jackson believed that both sides of the brain serve in the automatic use of words; and the left in that least automatic or most voluntary use of them, which is speech.—The PRESIDENT mentioned the case of an aphasic whose only phrase was, "God bless my soul!" and stated that he had at present under care a lady who, whilst retaining full intellectual power, was unable to express herself in speech.—Dr. HABERSHON, in reply, said that his patient no doubt understood what was said to him during the few hours that he retained consciousness.

Mr. A. T. NORTON described a new method for the Radical Cure of Web Fingers, which he had performed in a few cases. It consisted in the reflexion of a tongue of integument cut from between the knuckles and another from the palmar surface of the hand. These flaps being raised, the "web" is divided, and the superabundant tissue being removed, the flaps are brought together. The flaps should be sufficiently thick to obviate shifting, which had occurred in one case, where three fingers were webbed; they should be narrow, pointed, and of sufficient length.

Mr. DAVIES-COLLEY read notes of a case of Villous Growth of the Bladder, successfully removed by Perineal Incision. Henry W—, aged thirty-two, a shipwright, had suffered from hæmaturia for eight years. At first blood was passed only occasionally, and in small quantities. Latterly the flow had increased, and he had become so weak that for sixteen months he had been unable to work. He was admitted into Guy's Hospital last March. His family history was good. He was strongly built and fairly nourished, but very anæmic. There was a continual desire to micturate, and a feeling as if something always remained behind in the bladder. Blood was passed, sometimes at the beginning, sometimes at the end of micturition. No stone could be detected, and all efforts to find villous masses in the urine failed. No tumour could be felt per rectum. On April 16th he was placed under ether. Mr. Davies-Colley then opened the bladder by the usual incision for lateral lithotomy. At first nothing could be felt. Then a slight projection was made out on the left side of the fundus, and a cord-like process running from it. In a short time the free end of this process, with a soft pinkish tuft of villi attached to it, was seen at the deeper part of the wound. This was seized with the forceps, drawn out, and the pedicle cut with a pair of scissors close to the wall of the bladder. No other growth could be felt. There was but little hæmorrhage during the operation, and some which occurred in the evening was readily arrested by the injection of iced water into the bladder. He made a rapid recovery. In two weeks the urine ceased to flow from the perineum, and soon afterwards the wound healed. When last seen, two months after the operation, there had been no return of the hæmorrhage. The irritability of the bladder had ceased, and he was in the enjoyment of perfect health. The tumour grew from the posterior wall of the bladder, at a point about three inches from its neck, and one inch to the left of the middle line. It consisted of a fibrous stalk one-sixth of an inch thick and two inches long, terminated by branching filaments from half an inch to three-quarters of an inch long. These filaments contained capillary loops, invested by many layers of epithelium of a cylindrical shape. Professor Humphry has recorded in the "Medico-Chirurgical Transactions" a case in which he successfully removed a fibrous polypoid growth from the male bladder. He mentions a similar success in Professor Billroth's practice. The chief difficulty in the male subject is to ascertain the presence of a tumour as the source of hæmorrhage. In the present case the diagnosis depended solely upon the long continuance of the bleeding and the absence of other causes. Perhaps the fact of blood passing sometimes at the beginning, at other times at the end of micturition, may assist in the detection of growth. No doubt the villi were in this case sometimes washed into the prostatic part of the urethra, where they were squeezed, so as to give rise to a flow of blood before the urine; while at other times hæmorrhage into the bladder was set up by the pressure of its muscular walls upon that part of the growth which lay in its interior.—Mr. CLEMENT LUCAS said that in these cases operative interference was justifiable and reasonable. He had thrice performed cystotomy in chronic disease of the bladder with great relief. The diagnosis of villous disease was not assured until a small portion of the growth could be obtained and detected by the microscope. These

cases often went on for years without much effect upon health. He had a case under his care for two years; astringent injections afforded some relief. Mr. Durham attempted the removal of a growth from the bladder a few years ago.—Dr. HABERSHON said that the patient on whom Mr. Davies-Colley had operated was very weak and prostrate on admission into the hospital, and it was evident that the hæmorrhage came from the bladder, and not from the kidneys. There was often great difficulty in the diagnosis of these cases. He remembered a case in which the symptoms were attributed by one to calculus in the bladder, by another to calculus in the kidney, and another to cancer. The patient suffered from hæmaturia, and at times intense pain in the penis. After three or four years' suffering a portion of a villous growth was passed per urethram, and all the symptoms ceased. Some pain returned after many years' interval. In other cases hæmorrhage continues; and in the presence of such cases it was a great advantage to know that operative interference might be undertaken with relief.—Dr. A. P. STEWART said that about twenty years ago he sent in to the Middlesex Hospital from the out-patient room a woman who had suffered for many months from intermittent hæmorrhage from the bladder, at times very profuse, then ceasing for weeks, and then returning. Mr. De Morgan made a digital examination of the bladder, but found nothing. The urine continued to contain blood at intervals, and ultimately the patient died. The bladder, with a pedunculated villous growth, is now in the hospital museum. The reason why it had not been detected by Mr. De Morgan was, that it was attached to the front wall of the bladder immediately under the pubes.—Mr. TEEVAN congratulated Mr. Davies-Colley on the case; the first and only case of successful removal of a villous growth by the knife. Civiale had removed one by the lithotrite. Villous growths were usually attached to the posterior wall of the bladder, whereas polypi were fixed to its neck. The diagnosis of such cases was difficult; and he mentioned one which he had lately seen with Dr. A. Clark, when in catheterism clear urine flowed at first, followed by pure blood and some shreds of villous growth. The patient was old and paralytic, so that attempt at removal of the growth was out of the question. Incision into the bladder for cystitis was done largely in America, and he himself had practised it four times, making the median incision. Perhaps an external urethrotomy would suffice; villous disease was not always fatal. He had seen a case where the mass was spontaneously extruded with recovery.—Mr. BARKER asked whether in the cases operated on by Professor Humphry and Professor Billroth the growths were as pedunculated as in Mr. Davies-Colley's case. In some cases the villous disease is distinctly sessile, and involves a large surface of the fundus of the bladder. Supposing a growth of that variety were cut down upon it would be difficult to know how to deal with it.—Mr. DAVIES-COLLEY, in reply, said that the tumours removed by Professors Humphry and Billroth were not of the villous kind, Prof. Humphry's was a case of polypoid fibrous growth from the mucous membrane. In his own case had the growth been sessile, no doubt great difficulty would have been experienced, but still, by tearing and scraping much might be removed, and the hæmorrhage checked at least for a time. It was generally possible to entangle a small portion of a villous growth in the eye of the catheter, and thus extract it for diagnostic purposes; and lately he had employed the washing bottle used in litholapaxy very effectually for the same purpose.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Gastric Ulcer.—Cancer of Liver invading Stomach.—Intestinal Obstruction from Contraction of Ileal Mucous Membrane.

At the meeting on December 13th, F. J. Gant, Esq., President, in the chair, Dr. ALLCHIN brought forward a case of Gastric Ulcer. Emily A—, single, age thirty-two, admitted into Westminster Hospital July 6th, 1880. Symptoms noticed only nine weeks previous to admission. She died on November 17th. Gastric ulcer on anterior wall, with pancreas for its base, three inches by one inch in diameter; edges clean cut. On admission there was

extreme anæmia, with pulsating tumour in epigastrium, rather to left of middle line. During the progress of the case the patient progressively emaciated, and finally died from hæmorrhage into the stomach. Absence of persistent vomiting was the only irregular symptom in the case, sickness only occurring on one or two occasions to a very slight extent. It is noticeable that this absence of marked vomiting was associated with an unusual portion of the ulcer—viz., in the anterior wall near to the greater curvature.—Dr. HABERSHON asked whether there were any more decided symptoms in the case. The ulcer could hardly have been on the anterior wall as its base was formed by the pancreas.—Dr. ROUTH referred to a case where the limited pain caused by a galvanic current to the epigastrium determined a diagnosis of ulcer, when other symptoms were deficient. The patient, a gentleman, died after profuse hæmorrhage, and the ulcer was found after death.—Dr. WILTSHIRE asked if melæna had been observed. It was a valuable symptom, and occurred often without hæmatemesis. Vomiting was more apt to occur when the ulcer was seated near the pylorus.—Dr. ALLCHIN said there was no history of hæmatemesis, but melæna occurred. Although mainly on the anterior wall the base of the ulcer adhered to the pancreas.

Dr. HABERSHON then showed a specimen in which a Cancerous Cavity in the Left Lobe of the Liver communicated with the Stomach, and an abscess between the liver and the diaphragm communicating with a second cavity in the right lobe of the liver. There was extreme anæmia, and a cancerous growth in the lung had produced local pleuropneumonia. The gastric symptoms were comparatively slight, the orifices were free, and the rest of the gastric mucous membrane was unaffected. The anæmia and the secondary affection of the lung masked the primary disease.—Dr. THOROWGOOD mentioned the case of a gardener who came under treatment in the morning, made a good meal; was afterwards taken with sudden collapse, and died the same evening. A large perforating ulcer of the stomach was found.—The PRESIDENT inquired as to the etiology of ulcer of the stomach, and whether this disease was so common as Dr. Brinton supposed.—Dr. HABERSHON, in reply, said these cases may be very slow in their progress, but when the ulcer is seated over a large vessel the case may be very quickly fatal. He mentioned a case where symptoms, after lasting forty years, subsided, probably from healing of the ulcer.

Dr. HABERSHON then read notes of a case of Obstruction of the Intestine from great contraction of the Mucous Membrane of the Ileum. The patient, aged thirty-five, was seen in consultation with Mr. F. E. Webb. He had been subject to attacks of colic and diarrhoea from boyhood, but had otherwise good health. In the autumn of 1878 he began to suffer from weakness, and paroxysmal abdominal pain recurring at shorter and shorter intervals; emaciation slowly taking place. The bowels were open but motions were pale. On August 3rd, 1879, there was great distension of the abdomen, visibility of coils of intestine, constant attacks of pain, especially in upper part; motions sometimes loose, sometimes forced. No tumour could be detected, and it was evident there was not complete obstruction. He died in December, and examination showed adhesion of a coil of small intestine to the transverse colon, with great narrowing of the ileum less by thickening of the mucous membrane, whilst above this point the coats of the bowel were much hypertrophied and ulcerated, but small and contracted below. This was no evidence of cancer. Dr. Habershon thought the contraction had existed for many years, and was probably of inflammatory origin—an intussusception in early life being suggested as an hypothetical explanation. He discussed the question of diagnosis, and reviewed the various causes of intestinal obstruction. The clinical history pointed to disease of the mucous membrane rather than to bands of adhesion, volvulus, or tumour; but it was thought probable that the disease had assumed a malignant character. The difficulty in distinguishing between obstruction of the large or small intestine was referred to, and in this case the symptoms pointed to the colon as the seat of disease. The adhesions to the colon probably caused the pain in this region. Prognosis was unfavourable from the first, and the treatment only palliative. Colotomy would have been of no use, but if the obstruction had become complete, an operation would have been resorted to, hence the importance of precisely localising the disease.—The PRESIDENT asked whether any attempt had been made to discover the seat of obstruction by means of abdominal

section. In all cases it was essential, if possible, to determine the nature of the seat of obstruction.—Mr. ROYES BELL alluded to the frequent impossibility of diagnosing the exact seat of an internal obstruction. He related a case where obstruction was thought to be due to an inguinal hernia which was operated on. The patient dying soon after a stricture of the small intestine was found a short distance above the hernia; and had it been detected at the time of operating an artificial anus might have been made in the bowel above the stricture.—Dr. DEHAVILLAND HALL related a case with symptoms of diarrhoea treated for several days with chalk and opium, when signs of obstruction set in, and he was admitted into the hospital in a sinking condition. Colotomy was performed at once, but patient died a few hours afterwards. The obstruction was due to cancer of the rectum.—Dr. HABERSHON agreed as to the obscurity of these cases. In the case he had read, the obstruction was not complete. Mr. Birkett had had a case under his care in which were three distinct sorts of obstruction. Dr. Habershon deprecated too early surgical interference, because in some of them all symptoms disappeared in the course of a few days.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Opacities in Vitreous Humour, following injury.—Retinal Hæmorrhages and Degeneration in Scurvy, and in Idiopathic Anæmia.—Congenital Absence of Eyeball.—Paralysis of Cranial Nerves with Hemiplegia.—Peritomy.—Eye Symptoms in Locomotor Ataxy.

THE ordinary meeting of this Society was held on the 9th inst., W. Bowman, Esq., F.R.S., President, in the chair. There was a good attendance, and many interesting cases were exhibited, and papers read by Mr. Critchett and Dr. Hughlings Jackson.

Mr. J. E. ADAMS exhibited and described a case of peculiar Opacities in the Vitreous Humour, following Injury. Within two weeks of receiving a blow on the right eye with a chestnut numerous minute shining bodies, like cholesterol, were detected in the vitreous. At first the pupil was weak and excentric, but it is now (two months after injury) normal, the vitreous remaining as before. The case was remarkable for the short time elapsing between the injury and the appearance of the bodies in the vitreous. Knapp had recorded a somewhat similar case.—The PRESIDENT thought it difficult to explain if it were due to the accident. Might not the bodies have been long present?

Dr. S. MACKENZIE described a case of Scurvy, with Retinal Hæmorrhages and Degeneration, in a young lad who had lived in Whitechapel, and had not been deprived of vegetable food. The gums were spongy; there were numerous purpuric spots on the skin; and whilst under observation hæmorrhages began to appear in the retina of both eyes, becoming more and more abundant, so that they now present the appearance of severe albuminuric neuroretinitis. He is very anæmic; there is no leucocythæmia.—Dr. BUZZARD doubted if the case were one of true scurvy, for if so it would be the first case he knew in which that disease had appeared whilst taking vegetable food. He had examined many cases of scurvy for retinal hæmorrhages, but without success. The case was rather one of purpura.—Dr. GOWERS asked if there was any considerable reduction in the number of red corpuscles.—Dr. MACKENZIE said the case was regarded by many as one of scurvy, although he admitted the force of Dr. Buzzard's arguments. He had hitherto failed to find retinal hæmorrhages in scorbutic cases. The red corpuscles were about twenty to thirty per cent. of the normal, and the hæmoglobin was very deficient. Dr. Mackenzie then mentioned a case of Idiopathic Anæmia in a man in whom retinal hæmorrhages were present, but had disappeared under treatment. It was usual for such hæmorrhages in anæmia to come and go. The corpuscular richness was at first only 20 per cent.

Dr. A. D. DAVIDSON showed a case of Congenital Absence of one Eyeball, a small rounded button lying beneath the conjunctiva at the bottom of the orbit, which was of natural depth. At birth there was a slight discharge from this orbit, but in answer to the President, Dr. Davidson said there was no appearance of inflammation.

Dr. ALLEN STURGE exhibited a man, aged seventy-two, who was admitted into the Royal Free Hospital five weeks ago in an attack of apoplexy. There ensued paralysis of both third nerves, partial paralysis of the levator palpebræ on the right side, slight on the left; dilatation of pupils, especially the left; right facial paralysis and deafness on the right side; and left hemiplegia. Recovery began in the arm first, and on the upper part of the arm before the hand. The facial paralysis, complete in degree but not in extent, improved in three weeks, and the ocular condition remained unaffected. There was a possibility of syphilis in the case (there was some old choroido-retinitis in the left eye), but the history pointed in favour of a hæmorrhage in the anterior part of the pons.

The following cases were exhibited, but for want of time not described. Mr. McHARDY: Case of Recent Rupture of the Choroid.—Mr. WORDSWORTH: Case of Rupture of both Eyeballs with subconjunctival dislocation of the lenses, by a single injury; recovery of good sight. Case of peculiar Granular Calcareous-looking Opacities upon the Iris after needle operations for soft cataract, in a boy.

Mr. CRITCHETT then read a paper on Peritomy, and gave the following reasons for introducing the subject to the notice of the meeting: First, that during a long career many cases of vascular opacity with granular lids had come before him in which the disease had remained for many years unrelieved, although the patients had been under treatment for considerable periods at various institutions; and secondly, because the operation of peritomy had fallen into unmerited neglect, and was seldom practised. He then proceeded to give a brief sketch of the leading symptoms of the disease, and alluded to the type of patient in whom it most frequently occurs, he having found that it is most prevalent in young adults who had been ill-nourished and neglected; and that it is frequently propagated by direct transmission, so that constitutional defects and local causes contribute in varying degrees to its development. It often exists in a more or less aggravated degree for many years; and the treatment is, as a rule, directed to removing the granular condition of the lids. This may be partially effected by the application of caustics and astringent lotions, but such treatment is rather palliative than curative, and not unfrequently during its progress the case will relapse and the symptoms become even more intensified. Mr. Critchett recommended—although it might seem contrary to the pathology of the disease—that curative treatment should in the first place be directed to the vascular web, which in these cases covers the upper third or upper half of the cornea, since he believed that the exciting cause of the relapses lay rather in this morbid condition, and that the granular state of the lids was kept in activity by the existence of the above-mentioned vascular membrane. He, therefore, in every case initiates his treatment by performing the operation of peritomy, since he finds that when sufficient time has been allowed (usually from four to six months) for the resulting cicatrix to become dense, white, and atrophied, thus cutting off the vascular supply to the partial pannus, the web gradually disappears, the cornea becomes transparent, and the granulations either take their departure or become much more amenable to ordinary treatment. He was anxious to dwell upon this last point, because for a certain period after the performance of the operation no benefit, but rather the contrary, would usually be observed, and it is only on the completion of the last atrophic stage of the cicatrix that the curative influence is established. He earnestly commended the operation to the attention of his colleagues. Three cases were shown illustrating the effects of treatment at different stages.—In reply to the President, Mr. CRITCHETT said that he extended the peritomy beyond the pannus—i.e., right round the eye.—Mr. HIGGINS had performed peritomy in many cases without result, and had therefore abandoned it. Possibly he had not observed the case long enough afterwards, and after Mr. Critchett's advocacy he would again perform the operation. Mr. STREATFEILD asked whether any treatment was adopted for the granular lids?—Mr. CRITCHETT said all the cases had granular lids, but he began by the peritomy, and in a large number of cases the granular condition subsides when the vascularity of the pannus is cured. In other cases the granular lids require additional treatment.—Mr. JAMES ADAMS had long been in the habit of performing peritomy, and was satisfied with the benefit resulting from it. He thought the cases should be selected. He had found that the pannus was not always dependent on granular lids, but the cornea was vascular from the first.

Dr. HUGHLINGS JACKSON then read a paper on the Eye-

Symptoms in Locomotor Ataxy, of which an abstract is given elsewhere. (See p. 968.)—Mr. SPENCER WATSON asked whether the optic atrophy of ataxies was peculiar and a special form.—Dr. JACKSON said that he had long ago pointed out its special features; and it was now generally admitted to be due to grey degeneration, and was characterised by limitation of the field of vision and loss of colour-perception.—Dr. GOWERS regretted that time had not allowed Dr. Jackson to read the whole of his paper. He had examined a number of cases of ataxy with myosis and loss of reflex action to light, and he could confirm Erb's statement that, in this condition the pupils did not dilate on stimulation of the skin. He thought, however, that we must hesitate in regarding this phenomenon as strictly analogous to the loss of other reflex actions in the disease, which were due to a lesion of the sensory structures or reflex centres. It might be the result merely of the motor paralysis of the sympathetic fibres for the dilator pupillæ. This view was confirmed by one case which he had seen, in which, although there was loss of reflex action to light, there was not myosis, and the pupils did dilate on cutaneous stimulation.

Reviews and Notices of Books.

St. Thomas's Hospital Reports. New Series. Vol. X. Edited by Dr. ROBERT CORY and Mr. FRANCIS MASON. London: J. & A. Churchill. 1880.

St. George's Hospital Reports. Vol. X. Edited by T. T. WHIPHAM, M.B., and T. P. PICK, F.R.C.S. London: J. & A. Churchill. 1880.

THESE volumes, which each contain full statistical tables and summaries of the cases treated in the hospitals during the year 1879, have appeared with commendable punctuality. They present certain points of difference in the manner in which they are drawn up, but each is excellent in its way. Far greater space is allotted to the actual "reports" in the St. George's volume, but we miss any general statistical table of the medical cases similar to that furnished in the St. Thomas's Reports. In the St. George's Reports each disease is treated separately, and references are given to the cases in the hospital registers. In the St. Thomas's volume some diseases are analysed in a tabular form, others by means of brief abstracts. But in both the amount of information is considerable, and the labour entailed upon the registrars in the compilation of the reports must have been very great. The medical report in St. George's is by Dr. Isambard Owen, in St. Thomas's by Dr. W. B. Hadden; the surgical in the former by Mr. W. H. Bennett, in the latter by Mr. H. P. Potter. The St. George's volume contains also two extended reports from the curator, Dr. Ewart, giving an account of the work done in the post-mortem room during the years 1878 and 1879. There are also reports from the various special departments, more or less full.

Preceding the analytical summary, and occupying the main part of the book in the St. Thomas's Reports, are several original memoirs by members of the staff. Dr. Peacock analyses critically 161 cases of rheumatic fever under his care from 1872 to 1876, in continuation of a previous paper dealing with cases before that period, and making a total of 394 cases, of which 205 were males and 189 females. Of this number 32.7 per cent. exhibited some form of recent cardiac disease; the total average of cardiac complications, old or recent, being 42.8 per cent. or one in 2.3 cases. The mortality was only 1.5 per cent. Mr. Nettleship writes upon Diphtheritic Ophthalmia and Congenital Day Blindness with Colour-blindness. In the first of these papers he includes all cases of membranous ophthalmia, which, he points out, is rare in association with pharyngeal diphtheria, but more common during, or after, measles and other exanthemata. Its greater prevalence in Vienna and North Germany is suggested to be due to the

greater prevalence of granular conjunctivitis there. A clinical lecture upon the operations for retention of urine dependent on stricture of the urethra, and delivered in 1852, is reprinted by Mr. Simon, in which the operation of external urethrotomy—opening the urethra by a puncture or small incision immediately in front of the prostate—was adopted. Dr. Ord contributes two papers upon Thoracic Aneurism, going very fully into the clinical features of the disease. Dr. Ord, in conjunction with Dr. Seymour Taylor, also contributes a detailed analysis of sixty-two cases of enteric fever treated in the hospital from August 1st, 1879, to March 31st, 1880. Dr. Stone has a paper on Hysteria and Hystero-Epilepsy, in the course of which he urges further investigation into the alleged efficacy of magnetism in the removal of the sensory disturbances met with in this neurosis. Dr. Sharkey has an interesting paper on a subject which has not hitherto received much attention, at least in this country—viz., the Initial Eruptions of Smallpox. These are erythematous or hæmorrhagic—the former simulating, but distinguishable from, the eruption of scarlet fever and measles. Amongst other papers may be mentioned that by Mr. Wagstaffe on lengthening of the limb as a result of knee-joint disease, and a paper by Dr. Cory upon some points in pathology and legal medicine derived from an examination of the bodies of fifty children born dead or shortly dying.

There are not so many original communications in the St. George's volume, in which the practice now is to subordinate this department to the reports. Surgical subjects predominate. There are three clinical lectures by Mr. T. Holmes. The first on a case of Ilio-femoral Aneurism, in which the iliac artery was tied with an animal ligature, after the failure of compression applied to the common iliac artery and during the progress of gangrene of the leg and foot. Amputation was performed—first of the leg, then of the thigh, and the patient eventually recovered in spite of an intercurrent double pleurisy and thrombosis of the other leg. The second lecture deals with a case of an old Fracture of the Patella reunited with wire sutures by the antiseptic method, after rupture of previously-existing ligamentous union. Mr. Holmes thinks that such an operation should only be resorted to very exceptionally, and shows from this case that it is one not unattended with considerable danger. His third lecture is on a case of successful Subperiosteal Resection of the Tibia (eight inches of bone being removed), the shaft being divided somewhat below the upper epiphysis. The abscess had made its way into the ankle-joint before the operation, and the patient was in a very collapsed state for a short time after its performance. Mr. Pick publishes a clinical lecture dealing with the Treatment of Wounds after Amputation during the past twenty-five years, an interesting historical survey, demonstrating the gains derived by the antiseptic method. Mr. Edward Stirling writes upon the Cutaneous Eruptions occurring after recent operations and injuries. His main thesis is "that the rash and febrile symptoms which occur frequently as the immediate sequel of an operation are often those of scarlet fever; that the fever is in some way, as yet undetermined, dependent on the presence of the wound; and that when scarlet fever occurs under these circumstances it undergoes certain deviations from the normal type of this disease." But he further advances evidence to show that sometimes an erythema occurs resembling scarlet fever, though independent of it; and that other eruptions of different type may similarly occur. Mr. Morgan contributes a paper on the diagnosis of Hip Disease; Mr. Gaskoin on Ichthyosis; and Mr. Howard Barrett on some cases of Tubercular Meningitis. Mr. Bertolacci records a case of Diabetes, illustrating the effects of codeia, carbolic acid, and salicylic acid; and also describes a modified method of the Quantitative Estimation of

Diabetic Sugar by Fehling's solution, and an ingeniously-contrived urinometer. A few other brief papers complete the volume, which also contains an interesting memoir of the late Mr. Thomas Tatum.

Thus it will be seen that these two volumes abound in the results of careful clinical observation, and that they are in every sense reports of much earnest and thoughtful hospital experience.

Surgical Enquiries, including the Hastings Essay on Shock, the treatment of Surgical Inflammations, and numerous Clinical Lectures. Second Edition. By FURNEAUX JORDAN, F.R.C.S., Surgeon to the Queen's Hospital, Birmingham, &c. London: J. and A. Churchill.

IN no way is the originality which marks Mr. Jordan better shown than in the form chosen for this work. It is a striking contrast to the encyclopædial and elaborate style that now so largely prevails, but is a simple record of many interesting cases which have come under Mr. Jordan's care, or of careful investigations he has made, and is still richer in ingenious suggestions and contrivances. It is essentially a personal book; it is Mr. Jordan, and himself alone, his experience, his views, his hopes, his fears; and as such it is a very valuable book. No provincial surgeon is better known than Furneaux Jordan, and his acknowledged practical skill is equalled by his scientific ingenuity. It is difficult where there is so much of interest to pick out any of the sections for special comment; many of the chapters have been read to various Societies, or already published in medical periodicals, and are therefore familiar to our readers, to whom we can honestly recommend the book as well worthy of study.

Analytical Records.

STEARINE PAPER.

(MULLARD BROS., PENN-STREET, NEW NORTH-ROAD.)

THIN, semi-transparent and perfectly waterproof paper, intended for wrapping drugs and other goods which might be injured by damp. The idea is an excellent one, and the paper will be particularly useful at Christmas time, when books and delicate articles are sent in such numbers by post and rail.

MALTED COCOA.

(J. S. FRY & SONS.)

This is an excellent preparation of cocoa and malt extract. It is dried at a gentle heat to avoid injury to the diastase; its dietetic and digestive value is beyond all dispute, and it is very agreeable in flavour.

GRANULAR EFFERVESCENT IODATE OF IRON.

(YOUNG & POSTANS, BAKER-STREET, LONDON.)

This new remedy was suggested by Dr. C. Cameron of Dublin, and is well worth a trial, as there are inconveniences in the use of the iodide. Messrs. Young and Postans have made the preparation with their usual skill.

PILSENER LAGER BEER.

(F. JACOB & CO., GRACECHURCH BUILDINGS, LONDON.)

Light, sound, and pleasant ale, which many persons could drink who are unable to touch stronger beer. We fail, however, to perceive that it possesses any remarkable advantage over the English table ales now so commonly used in private houses. Many English brewers make such ale of excellent quality and of low alcoholic strength.

GUARANTEED PURE SOLUBLE COCOA.

(MANUFACTURED BY BENSCHDORF & CO., AMSTERDAM.—BRIESEN & HEYDEMANN, 13, COLEMAN-STREET.)

This is a very pure and strong cocoa of excellent flavour. It is well ground and mixes easily. We can have no hesitation in praising it highly.

THE LANCET.

LONDON: SATURDAY, DECEMBER 18, 1880.

MR. LISTER must feel—he may justly feel—a sense of gratification at the honours which accumulate upon him in his own country. Year after year one country after another has conferred upon him the highest proofs of its esteem, sometimes in a medical and sometimes in a larger scientific sense. Germany, Austria, France, Norway, the United States, all agree. But it is possible for a man to be satiated with foreign praise, and to be stinted of it at home. A prophet may not be without honour save in his own country.

This is not MR. LISTER'S case. In both Scotland and England he has held Royal Appointments. Royal Societies have done all they could to do him honour. The Philosophical Transactions and the Transactions of the Royal Society of Edinburgh have been open for the record of his original and important researches in physiology and pathology. The medical press—speaking for ourselves at least—has never felt more satisfaction than in being the medium of those papers on antisepticism which have made an epoch in surgery, and which imply a keen appreciation of the present state of biological science and of its application to great practical and surgical ends. Within the last few weeks two very conspicuous tributes have been paid to MR. LISTER. One of the medals of the Royal Society has been accorded to him, chiefly, according to the President's speech, on the ground of his work in regard to antisepticism, but generally with reference "to his numerous and valuable contributions to physiological and biological science during the last thirty years." This action of the Royal Society will be approved throughout the scientific world, and by the medical profession in this and all countries. It is not more creditable to MR. LISTER than it is to the Royal Society, which might do a little more than it does to recognise the claims of medical men as a very important part of the great body of scientific workers—claims which the State in this country is so slow to recognise. MR. LISTER will prize this compliment as one paid to him by men who view his work from the strictly scientific and biological standpoint.

But another honour has accrued to him within the last few weeks. He has been nominated by the Council of the Clinical Society as the next President. However much honour a man may receive from the outside, as it were, it is pleasant to have the praise of brethren, and we may be very sure that if within three or four years of his coming to London MR. LISTER is offered the chair of one of its most vigorous and thriving Medical Societies, there is no honour which medical men or societies in London can give which will be long withheld from him. We have spoken as if this last honour to MR. Lister were assured. It is a little premature to speak so, for, according to the rules of the Clinical Society, the election is in the hands of the members at the annual meeting, and all that has been done,

so far, is the act of suggestion or nomination by the Council. But even if this suggestion were not acted upon at the general meeting of members, it would not the less be a great honour to MR. LISTER. Those who criticise the nomination do so in no absolute sense. They point out that MR. LISTER has been but little identified with the proceedings of the Clinical Society, that he has never contributed a communication to its Transactions, and that his occupancy of the chair could easily wait for another turn of the wheel. There is a great amount of truth in such a view of the case, the more so when it is remembered that the Clinical Society has been favoured by the active participation in its proceedings of several of our foremost surgeons, and that no Society can afford to disregard those of its members who, though prominent and busy in practice, make time to attend its meetings. Our contention is that even if such views find expression at the annual meeting, a great honour to MR. LISTER must still remain. He has been nominated by the Council, which contains a very fair representation of the leading surgeons and physicians of London, and even if in this they may prove to have been a little premature, and perhaps unmindful of the strong claims of one or two of their own number, it will remain that they have paid a high compliment to the author of the antiseptic system of surgery.

THE Metropolitan Asylums Board is still much exercised as to the question of hospital accommodation for cases of small-pox. The available permanent accommodation for cases of small-pox in its hospitals is practically exhausted before even the disease can be declared to be epidemic. The reserve accommodation at Hampstead is, for the present, closed against them, and the counsels of the Board are divided. Some would follow the from hand-to-mouth principle, making such additional provision as the facts of the case showed to be necessary; in other words, copy the unavoidable policy of 1871-72, and endeavour to overtake the requirements as the disease surged on in front of them. Others would take time by the forelock, and make such provision at once as would enable them, while they may, to struggle on somewhat equal terms with the advancing malady; and this, we are glad to find, is the policy most in favour with the Board. But the Board is hampered with the undecided Hampstead hospital case, and is likely to be still more hampered with the public prejudices against small-pox hospitals. It is almost incredible that, notwithstanding the serious part this question of hospital accommodation, and the local influence exercised by small-pox hospitals, must play in any future extension of small-pox in the metropolis, we are still as far as ever from precise knowledge on this subject. The Local Government Board must be held entirely responsible for this grave neglect of their function of inquiry, and for whatever consequences may arise from it. It is no longer the public who are chiefly unsettled on this matter, for the medical profession themselves are becoming unhinged by this persistency of doubt. A significant evidence of this is afforded by a reported recent utterance of Dr. TRIPE, the medical officer of health for Hackney, to the District Board of Works. He is represented as saying to his authority, that a large proportion of the cases of small-pox which have taken place in his district "occurred within a comparatively short distance from the

small-pox hospital (Homerton)," and that "he is fully persuaded that an aggregation of 140 small-pox patients in so small a space must be a source of great danger, and is entirely opposed to the present state of medical knowledge on the subject." The vagueness of these statements (assuming them to have been made) in a matter admitting of precise knowledge of the facts is their own condemnation. Dr. TRIPE must settle with the college in Pall-Mall as to his right to pronounce on the general state of medical opinion on the subject, but we admit that the expression has a strong flavour of the sort and quality of opinion which may be expected to be found there. It is simply scandalous that the public should be left to the mercy of its own prejudices and of vaguely expressed opinion on this question; and for this, we repeat, the Local Government Board must be held responsible, for it alone has the necessary powers and means for making due inquiry. Meanwhile the practical difficulty of having to contend with the obstacles which arise from the want of the knowledge in question falls upon the long-suffering Metropolitan Asylums Board.

But this question of the influence of small-pox hospitals upon a neighbouring population is, after all, but a by-question in the more important subject of the real meaning of these recurrent outbreaks of small-pox in the metropolis—of the speciality in the culture of small-pox evidently existing in the metropolis. What are the precise defects in the administration of the vaccination and sanitary laws in the metropolis which permit, or contribute to, the exceptional prevalence of small-pox in the metropolis? We assume that there must be such defects; for big as the metropolitan population may be, it is difficult to conceive that either the amount of its migratory population, or the normal accumulation (so to speak) of unvaccinated children, is such as to place the metropolis at so great a disadvantage in this matter with the chief towns of the provinces. At any rate, the subject is one admitting of a definite explanation, and had the disease been any other than small-pox we should certainly have had this explanation long ago. But unhappily we have to look for it from the Local Government Board, who persistently regard it as wholly a Poor-law question. The Metropolitan Asylums Board is essentially a Poor-law body; vaccination is administered through the Poor-law guardians; and it would seem as if the Local Government Board could not look upon this question of small-pox as it looks upon the question of any other disease with which it has to deal. It begrudges neither time nor care in investigating outbreaks of typhoid fever, or diphtheria, or scarlet fever; but it appears to regard small-pox as a Poor-law speciality like itch or contagious ophthalmia. In view, no doubt, of the indifference, or failure of clear apprehension, which has been displayed by the Local Government Board in this matter, *The Times* suggests the appointment of a Royal Commission to inquire into the prevalence of small-pox in the metropolis. We should have preferred an inquiry on the exhaustive plan pursued by the Medical Department of the Local Government Board in such inquiries; but we must confess that the course pursued by that Board has probably so prejudiced it in the eyes of the public in this matter that a Royal Commission might for public purposes be the best thing to have recourse to.

UNDER the direction of VON RECKLINGHAUSEN of Strasbourg, an investigation into the condition of the minute arteries of the body in granular kidney disease has been made by Dr. SOTNITSCHESKY. The controversy between JOHNSON on the one hand, and GULL and SUTTON on the other, has excited much interest in Germany, and several investigations have been undertaken, with results which differ not less than those of the original observers. EWALD has confirmed in the fullest manner the conclusions of JOHNSON; and EWALD, BARTELS, and BUHL agree in regarding the renal affection as the primary change, the arterial disease as a secondary effect, while ZEIGLER regards the arterial sclerosis, which he finds, as a cause of the renal disease. The latest contribution to the controversy is that by SOTNITSCHESKY, contained in the last number of Virchow's *Archiv*. He has examined the minute arteries in seventeen cases of renal disease. Thirteen had genuine granular degeneration of the kidneys, all accompanied by hypertrophy of the heart. Three presented senile atrophy of the kidneys, and one presented "glomerulitis," with recent round-celled infiltration of the interstitial tissue, without contraction. Vascular changes were found in fifteen of the seventeen cases, and hypertrophy of the heart in fourteen. Among the latter were six cases, in which, besides the thickening of the small arteries, there were no other changes in the vascular system by which the hypertrophy of the heart could be explained. In two of the other cases, however, there was valvular disease, and in six there were atheroma and sclerosis of the aorta, so that the hypertrophy of the heart could not be with certainty ascribed to the changes in the minute arteries in these cases.

In no case could SOTNITSCHESKY distinctly see a hypertrophy of the muscular coat of the smaller arteries. In five cases this coat appeared normal; in other cases, in which the middle coat appeared thickened, the thickening was apparently due to a growth of connective tissue extending among the muscular fibres, from the outer or inner coat. In many cases the nuclei of the muscular coat appeared lessened in number or in size, and as if atrophied. In fresh preparations he found the appearance described as "fatty degeneration of the nuclei." Whenever there was obvious thickening of the walls of the smaller arteries, both the adventitia and the intima appeared to be thickened, and densely fibrous, and in some instances they appeared to be in contact, from atrophy of the muscular coat. In three cases there was a special change in the inner coats, which then consisted of two tolerably dense layers. The outer of these apparently corresponded to the inner elastic lamina, and consisted of a refracting translucent substance, containing, near the muscular coat, small nuclei of irregular shape, which looked like imbedded muscle-nuclei. The change was marked in the arteries of the kidneys, the pia mater, and the spleen. In all there was typical granular degeneration of the kidneys and hypertrophy of the heart, without any other vascular lesion to which the hypertrophy could be ascribed. The changes in the organs named were always greater than in the arteries of the liver, and were least in the lung.

The facts ascertained, while differing somewhat from those of GULL and SUTTON, support their views rather than those of JOHNSON and EWALD. The facts are too limited in range to

throw any light on the order of development of the changes in the kidneys and general system respectively. But the author indicates certain facts which seem to him to point in the same direction as to the character of the histological observations. In all the cases of typical granular kidney the changes in the small arteries were present. In six cases the alterations were combined with chronic endocarditis. Fifteen of the patients were over fifty years of age, at the period of life in which arterial disease is frequent, independent of renal changes. This is regarded as increasing the probability that the renal disease in these cases was only part of a general change. In three cases there was no distinct hypertrophy of the heart, although the thickening of the walls of the minute arteries was conspicuous. This does not confirm the view that the change in the vessels is in any way the result of the hypertrophy of the heart, but agrees with the theory that the hypertrophy of the heart is purely secondary, and it is not yet proved that similar degeneration can occur as a consequence of the hypertrophy of the heart which owes its origin to local valvular disease. Moreover, SOTNITSCHESKY has found in some old persons, without cardiac hypertrophy and without renal disease, a similar change in the small arteries. But, as he points out, none of these facts constitute evidence against the assumption that this arterial change may also occur as a consequence of the blood change which is due to chronic renal disease, just as it apparently occurs as a consequence of chronic alcoholism or gout.

It is probably the general belief of a benevolent public that no, or exceedingly few, instances of the secret detention of persons of weak or unsound mind could now be found throughout the country. It is unpleasant to have this comfortable persuasion disturbed. Nevertheless, it is better to know the facts, and there is reason to fear the full truth is only half suspected. Since the Lunacy Laws have been administered with discretion as well as vigour, there can be no question that the concealment of cases of idiocy and imbecility has been greatly reduced; but there is still a broad margin of doubtful area which has not been touched. When a member of any family shows signs of being, or becoming, weak-minded, if he or she—especially when the patient is a female—is quiet, there is great reluctance to put the sufferer away in an asylum, nor is there often any recognised need for so doing. The law does not require that a case of this class shall be reported to the Commissioners in Lunacy, unless those who keep the patient are in some way reimbursed for the expense they incur. Parents may keep their children, and children their parents, brothers their sisters, and the like. The result of this state of matters is that a course of secret detention begins in kindness and quite innocently. After a while the weak-minded person may either become weak of body or partially paralysed, perhaps with short paroxysms of excitement occurring at long intervals, or she may have fits, or in some way or other come to be unrepresentable. For various reasons, and with what seem to be excellent excuses, the sufferers of this class are in process of time relegated to the more private parts of a house and kept away from sight, until at length they sink out of the family circle and come to be burdens and reproaches. Unless some more than commonly strong-minded member of the household

moves in the matter, the mind-cripple is forgotten, or, as far as may be, hidden from view, until the changes, which must needs occur, place her at the mercy of those who shrink from the disgrace of confessing that they have an idiot in the family, and, unmoved by compassion, convert what was at first a retreat into a prison. It is to be feared there are still *many* such instances of unintentional cruelty, even in respectable and well-conducted households. The only sufficient remedy for this state of matters is the incorporation, in any Act which may hereafter be passed to consolidate or amend the Lunacy Laws, of a clause expressly requiring the registration of *every* person who is not in a state of mind to exercise full control of his or her own person and property. There should be no property-qualification for the privilege of protection, and no excuse for non-registration should be allowed to lie in the fact that those in charge of these weak-minded or insane persons do not benefit by their custody.

Annotations.

"Ne quid nimis."

MEDICAL EDUCATION.

THE bulky correspondence we have received on the subject of medical education testifies, on the one hand, to the prevalent opinion that the existing arrangements are defective, and shows, on the other, the difficulties that stand in the way of any satisfactory reform. Everyone allows that something should be done, but scarcely any two persons are agreed as to what ought to be done. Some of the suggestions that have been made are mutually destructive, and others impracticable, though ingenious. It is, however, something gained when a general interest has been awakened and the existence of growing evils recognised and acknowledged. The remedy may be hard to find and unpleasant in its operation when it is found; but it does exist, and must sooner or later be administered. If the time be not already come, it cannot be far distant when, to escape actual deadlock or disaster, all the regulations relating to medical education and examination will have to be revised and radically altered. Meanwhile the subject needs ventilation, and demands the consideration of all thoughtful men.

A PRESCRIBING CHEMIST.

IN commenting lately on the relations between doctors and chemists, we alluded to the practice of counter-prescribing, which has increased rapidly under legal protection, as not merely injurious to the medical profession, but also to the sufferers prescribed for. A striking illustration of this has been afforded by facts brought to light at a recent inquest at Topsham, Devonshire, which shows also that chemists do not mean to content themselves with prescribing at their counters. A man, who had often before suffered from an affection of the throat, found his throat again becoming painful on Friday, Nov. 26th. On the following Tuesday he sent for a chemist, named Ellis, who attended him, gave him some gargle for the throat and mixture to be taken, and ordered linseed-meal poultices. The following morning the chemist visited him again, and said that he was to continue the gargle and send for some more medicine. Between nine and ten the same night, Ellis again saw his patient and ordered him, as "some of the ulcers in the throat were broken," to discontinue the gargle and go on with the medicine. During the night the man became restless and was thought to be dying. The chemist was again sent for, but declined to go. Dr.

Bothwell was sent for, but before his arrival the man was dead. In examination at the inquest, the chemist stated that the man's uvula was white, and Dr. Bothwell expressed to the coroner his belief that death arose from diphtheria, although without an autopsy it was impossible with certainty to say. In answer to a jurymen, Ellis stated that his visits to the deceased were not professional ones, but simply "for his own satisfaction," and made this statement although the man had sent for him, he had examined the throat, and after each visit had directed the treatment. After a short consultation, the jury returned a verdict of "death from natural causes." There can be little doubt that if the man had been attended by a "herbalist," who would probably have possessed as much knowledge of disease as the chemist, and as much moral right to take charge of the patient, the verdict would have been one of "manslaughter." Whether death arose from "natural causes" or not, there can be little doubt that it was a "natural effect" of the system of prescribing by chemists, of the dangers of which it constitutes so striking an example.

"LISTERIAN" OVARIOTOMY.

THE opponents of "Listerism" are gathering their forces and showing battle in earnest. At the Royal Medical and Chirurgical Society last Tuesday the challenge was given in uncompromising terms, and facts, backed by statistics, were largely used both in opposition to and in support of the practice and of the doctrine underlying it. The battle-ground selected was a comparatively narrow one, but it was a field which years ago was the scene of much hot debate—viz., ovariectomy. In February last Mr. Lawson Tait was the first to bring forward facts tending to show that this operation was not rendered more expeditious or safe by the adoption of antiseptic precautions; and on that occasion he found himself almost alone, although many took part in the debate. This time it is Dr. Bantock, of the Samaritan Free Hospital (whose colleague, Mr. Thornton, is the chief supporter of "Listerian ovariectomy"), who leads the attack, advancing beyond the position taken up by Mr. Tait, and ascribing to the use of carbolic acid most of the pyrexial and other untoward symptoms that have occurred in cases of ovariectomy which he had performed under what he alleges were true "Listerian" precautions. It is not easy to reconcile the almost diametrically opposite conclusions arrived at by Dr. Bantock and Mr. Thornton in this matter. Take only the question of pyrexia. The first-named gentleman believes its severity due to the toxic effects of the carbolic acid used in the spray, and states that in proportion as he has reduced the strength of his solutions, there has been less and less pyrexia in his cases. The latter declares (and supports his statement by statistics) that the employment of strict antisepticism is accompanied by a marked diminution in the number of cases in which pyrexia follows the operation; although it does not entirely prevent it. Mr. Tait quotes from his own experience facts strongly confirmatory of Dr. Bantock's thesis; Mr. Spencer Wells, on the other hand, goes even beyond Mr. Thornton in averring that the occurrence of fever in antiseptic ovariectomy is of extreme rarity. It is hardly surprising, then, that in the face of such statements, Mr. Savory should remark, somewhat caustically, that the question was not one of the method in which cases were treated, but of the personal skill of the operator; or that Mr. Holmes should, with his accustomed judicial impartiality, pronounce that the case for Listerism was "not proven"; although he went rather far in stating that neither the theory nor the method was understood by those who believed in the one and practised the other. English surgeons are becoming on this question so distinctly divided into two camps that we fear the suggestion we are about to make likely to

be almost debarred from acceptance. Still it is worth some consideration—and it is that a committee composed as far as possible of those who have no strong bias either for or against the method, be appointed by the Royal Medical and Chirurgical Society to investigate thoroughly the comparative merits of the two methods of treatment as applied to ovariectomy; to minutely consider—not statistical results alone—but the circumstances of a given number of cases of each method from all points of view, and if possible to draw conclusions which may be accepted by all. There may be insuperable difficulties in the way of such an inquiry; but, at any rate, it is worth attempting, if it be only to decide whether the measures of Listerism are, as alleged, open to the grave objections urged against them.

WHOLE-MEAL BREAD.

IT is economically and physiologically desirable that the whole grain should be used in making flour for bread. It is more natural and better that the elements should be taken as they are found combined in nature than that any portion of the whole, which may have been eliminated in the process of preparing flour, should be supplied by addition. At the same time, if the natural article can only be secured at the cost of irritating the stomach by swallowing small pieces of unpulverised husk, we must consent to remain without the luxury of whole-meal. Why are these conditions forced on us? It is quite possible to grind the whole-meal as finely as the grain alone, and the flour, though less white in colour than that which is prepared solely from the grain of the wheat, may be as soft and delicately sifted. The public have a mistaken impression that bread made from whole meal must needs be like what is commonly called brown bread. In order to pave the way for a better and more digestible supply of bread made from finely or perfectly triturated whole meal, we would suggest that this erroneous and mischievous notion should be dissipated. The imperfectly ground meal produces painful diarrhoea by mechanically irritating the stomach. Let the meal be ground as fine as common flour, and sifted again and again until it is perfectly pulverised, and the sole objection to whole-meal bread will be removed.

NEURALGIA AS A "WARNING."

THE great prevalence of "neuralgia"—or what commonly goes by that name—should be regarded as a warning indicative of a low condition of health, which must necessarily render those who are affected with this painful malady especially susceptible to the invasion of diseases of an aggressive type. This is the season at which it is particularly desirable to be strong and well furnished with the sort of strength that affords a natural protection against disease. There will presently be need of all the internal heat which the organism can command, and a good store of fat for use as fuel is not to be despised. It is no less essential that the vital forces should be vigorous, and the nerve-power, especially, in full development. Neuralgia indicates a low or depressed state of vitality, and nothing so rapidly exhausts the system as pain that prevents sleep and agonises both body and mind. It is, therefore, of the first moment that attacks of this affection, incidental to and indicative of a poor and weak state, should be promptly placed under treatment, and as rapidly as may be controlled. It is worth while to note this fact, because, while the spirit of manliness incites the "strong-minded" to patient endurance of suffering, it is not wise to suffer the distress caused by this malady, as many are now suffering it, without seeking relief, forgetful of the condition it bespeaks, and the constitutional danger of which it is a warning sign.

THE PARKES MUSEUM.

THE efforts of the Executive Committee to disseminate a knowledge of the laws of health among the classes which are most in need of such knowledge, and upon whose proper instruction the safety and health of the community at large so greatly depend, are, we are glad to state, fully appreciated. It will be remembered that last year a series of demonstrations, attended by some hundreds of persons, were given to artisans, builders' foremen, and clerks of works, and this year a fresh series has been inaugurated, for the benefit of members of building societies. On Saturday last (Dec. 11th) between sixty and seventy persons assembled to hear a discourse from Mr. E. C. Robins, F.S.A., "On the Situation and Construction of Dwelling-houses." In the course of an hour, Mr. Robins reviewed some of the chief points to which attention must be directed by those who set about to build a house. He advised that, where possible, houses should face east or west; that ground "made up" of rubbish, &c. should be carefully avoided; that the whole area of the ground occupied should be concreted, and that damp-proof courses should never be omitted from any of the walls, and that external walls should never be less than fourteen inches, notwithstanding that nine inches was permitted by the Building Act. Details of construction were then dealt with, and Mr. Robins insisted that all engaged in house-building should endeavour to understand some of the principles of architecture. Materials for building and ornamentation were then passed in review, the lecturer's remarks being illustrated by many of the articles contained in the Museum. The next lecture, on Jan. 8th, on "Ventilation, Lighting, and Warming," will likewise be by Mr. Robins, and others will follow by Professor Corfield and Mr. Rogers Field. The Executive Committee has lately been strengthened by the addition of the names of Captain Galton, Mr. Robert Rawlinson, and Mr. Robins; so that now every branch of hygiene is thoroughly well represented, and in a committee of sixteen persons there are four physicians, three surgeons, two members of the Local Government Board, one professor of hygiene, three architects, two engineers, and one surveyor.

SPEECH FOR THE DEAF.

THE International Congress on the Education of the Deaf, held at Milan in September last, and of which the official report of the proceedings is now published, declared that, considering the incontestable superiority of speech over signs in restoring the deaf-mute to society, and in giving him a more perfect knowledge of language, the oral method ought to be preferred to that of signs for the education and instruction of the deaf and dumb. The Congress further declared that, considering that the simultaneous use of speech and signs has the disadvantages of injuring speech, lip-reading, and precision of ideas, the pure oral method ought to be preferred.

The papers read at the Congress in illustration of the method here approved were full of interest, as showing not only the mental, but also the physical advantages derived from it by the deaf and dumb. In this connexion a thoughtful paper included in the proceedings, on the Health of Deaf-mutes, by Dr. E. Symes Thompson, deserves the special attention of medical men. It shows that under the simple phrase "speech for the deaf," a system of bodily and mental regimen of the highest importance for the welfare of the unhappy deaf-mute is included. We are glad to find that the system approved by the Congress, which is popularly known as the "German" system, is gradually making its way in England. The oldest institution for the education of the deaf and dumb has recently determined to abandon their old system in favour of the so-called German or oral method. The education of the deaf and dumb may therefore be

said to have been completely revolutionised. The attention of the public in this country was, for the first time, directed to the oral system of the education of the deaf by Mr. Dalby, in a paper read at the Social Science Congress at Leeds in 1871. The subject gave rise to much discussion, and was met by considerable opposition on the part of those whose profession it was to educate deaf children, and who had followed the system then almost universal in England, termed dactylogogy, or talking on the fingers. Since then the oral system of education has been followed and propagated in an energetic manner by the Association for the Oral Instruction of the Deaf and Dumb.

UNIVERSITY COLLEGE HOSPITAL.

THE fine range of baths which were erected a few years back at this hospital by the public spirited energy of Dr. Tilbury Fox are henceforth to be thrown open for the benefit of patients recommended by members of the medical profession. The committee announce that Wednesday and Thursday in each week will be partially devoted to the needs of patients of medical practitioners. Wednesday will be set apart for females, and Thursday for males. Between the hours of 2 and 5 o'clock P.M. the charges will be 5s. for mercurial and sulphur baths and 3s. 6d. for other kinds of baths, and between 6 and 8 o'clock P.M. the charges will be somewhat lower. On payment of a fee of half-a-crown the patients of medical practitioners will be allowed to use the baths at times other than those specially set aside for private patients. Every patient will be obliged to bring a written recommendation from his or her medical attendant specifying the nature and number of the baths. This, together with the necessary fees, must be presented to the secretary or his representative, and no fees will be permitted to be given to the bath attendants under any consideration whatever. The baths thus rendered available for the general public are of every description; plain water, medicated water, Turkish, vapour, mercurial, sulphur, needle and douches of all descriptions; and we doubt not that the medical profession will be glad of the opportunity afforded them of giving their patients the advantage of such complete arrangements for balneo-therapeusis.

POISONING AT THE STANHOPE HOUSE INDUSTRIAL SCHOOL, BRISTOL.

ON the afternoon of Nov. 30th, several girls in this establishment were seized with sudden sharp griping pain in the region of the stomach; in some cases this was so severe as to cause a sudden fall to the ground. The pain recurred at frequent intervals, and was so intense that the patients writhed in bed. There was frequent vomiting, especially after any food (milk) was taken. There was no blood in the vomit, and it was not bilious. There was marked constipation. Next day, and on the succeeding (Dec. 1st and 2nd), more girls were attacked with the same symptoms. On the 3rd inst., Dr. Atchley, the honorary medical officer to the institution, directed that no food in the house should be used, and that the various articles required should be obtained from tradesmen other than those who ordinarily supplied the institution. On this day several fresh cases occurred. On the 4th, two other girls were seized with the same symptoms; these patients had complained of a little pain before the food-supply was changed. After this no fresh cases occurred. In no case were the symptoms so severe as to cause anxiety as regarded the result, and the patients have gradually recovered. At the present time there remains only one who vomits occasionally. The treatment adopted was the administration of ten-drop doses of laudanum every hour till the pain was relieved. Dr. Atchley is of opinion that the symptoms of poisoning were due to lead, from consideration of the following points: the severe

and persistent colic, the frequent vomiting, the marked *constipation*, and the presence in one case of a definite blue line, in three other cases of a more doubtful line, on the gums. All the articles of food in the house were analysed by the city analyst, and pronounced free from injurious matter, the water was also examined, after standing in the pipes, and was found to contain the small quantity of one-fiftieth of a grain of lead per gallon. It was, therefore, impossible to discover the exact nature and source of the poison. After the report of the analyst on the 7th inst., the food was again supplied from the sources from which it was obtained previous to the outbreak, and no fresh cases of poisoning occurred.

LONDON FOGS.

WE are glad to see that Dr. Alfred Carpenter, having regard no doubt to a well-known apophthegm, had a good word to say, on the 8th instant, at the Society of Arts even for London fogs. They are not wholly so black as they have been painted, and may prove, after a fashion, a certain set-off against the consequence of engineering blunders in our sewers. We shall leave Dr. Carpenter to settle this little by-question with the engineers themselves, but if he be right we are placed in the awkward position of seeking to do away with an intermittent good while maintaining a continuous evil. The point is a nice one for tender consciences which resent Dr. Carpenter's trenchant method of dealing with it. Fogs appear to have a peculiar charm for this gentleman, considering that he lives outside the true London fog area. The details into which he entered on the 8th betrayed this, but still they in several respects showed the experiences of the dilettante, not the experiences of the individual who had been duly suffocated with them, or who on Christmas day last (day of dreadful memory) lost his Christmas dinner with his friends, unable to go out in the fog, and found his larder unprovided with dinner at home. Dr. Carpenter's address served chiefly to show the difficulty of dealing practically with London fogs for purposes of amelioration. He confined his recommendatory observations to the means, present and prospective, of diminishing the smoke element, which gives the peculiar characteristic to the London fog. He dwelt upon the substitution of gas for coal for many purposes, and the use of slow-combustion stoves for the burning of coal. But he confessed general disbelief in any measures unless the Legislature stepped in and compelled certain things to be done, and particularly imposed a tax on smoke-producing grates. He would have a Royal Commission appointed to inquire into the whole subject as preliminary to legislation. And here he is obviously right, for the subject is too complicated to be met by Acts of Parliament, except we have a clearer knowledge on what lines legislation should run. Meanwhile, let us hope that Dr. Carpenter will continue his useful mission of irradiating the hitherto seemingly hopeless subject of London fogs.

THE PROFESSION AND MEDICAL LEGISLATION.

THERE is good reason to believe that if the real unanimity of the profession on the great points of Medical Reform could be shown to the Government no difficulty would be experienced in inducing them to proceed with medical legislation. That such unanimity exists cannot be doubted, and it is within our knowledge that some practical steps for making it apparent are under contemplation. Time is precious, and we would urge promptness and thoroughness in the matter. Large votes of the profession have been taken on at least two occasions; but some years have elapsed since, and the question has grown considerably in the interval. New points have arisen on which Government would much wish to know the feeling of medical men. It marks some progress when a Government thinks it desirable to have the views of the profession as well as the views of the Medical Council.

THE LATE MADAME THIERS.

THE following circumstances in connexion with the last illness of the late Madame Thiers have been communicated by our correspondent in Paris; they will be read with interest:— Since her husband's death in September, 1877, Madame Thiers had devoted herself entirely to the glorification of his memory. Besides an almost daily pilgrimage to his tomb when in Paris, and the promotion of statues to him in the provinces, at the inauguration of which she always played the prominent part, Madame Thiers was engaged in the publication of his speeches, ten volumes of which are already issued. In their preparation for the press she displayed an amount of literary acumen which astonished those who were entrusted with the work. The deceased lady was a good Latin scholar. During the progress of this publication Madame Thiers was careless of her health, working hard all day long, sometimes breaking her fast only at 5 P.M., eating anything that happened to be at hand, and refusing to leave her occupation in Paris for necessary change of air.

A few months since she was seized with pains above the umbilicus, and there were other symptoms, which seemed to point to localised peritonitis. Some weeks later a tumour was made out, located either in the epiploon or mesentery. Hitherto the appetite and digestion had been good, but the liver becoming secondarily involved (great hypertrophy and nodulations), complete anorexia supervened. Then occurred thrombosis of the veins of both lower extremities, vomiting of black blood, and stools containing altered blood, from the stomach becoming involved. A week before death, when apparently moribund, oxygen was administered, and caused a temporary improvement. Two days before death vomiting ceased, and the stomach was able to tolerate light foods and stimulants—an ominous symptom, showing gastric anæsthesia, from nervous prostration. Finally, after remaining pulseless for twenty-four hours, the illustrious patient expired.

POOR-LAW MEDICAL OFFICERS AND MEDICAL RELIEF.

THE question of responsibility is every now and again raised in connexion with the refusal of medical officers under the Poor-law to attend cases at the request of paupers who have not taken the trouble to provide themselves with orders for medical relief. It cannot be too clearly laid down that medical officers are not required to attend without an "order" or a card for "Permanent Medical Relief," and that they do wrong by rendering assistance without such credentials. Medical men are not justified in creating a moral debt where no legal debt can be created. They may do great harm by yielding to impulses which seem to be inspired by motives of humanity. The possibility of procuring the "doctor's" aid at the last minute makes poor parents delay their applications to the relieving officer or the overseers until the time for useful action is past. Again, abuses of the most irritating kind arise from the practice of giving medical services without an order. We strongly recommend Poor-law officers to act strictly according to the instructions embodied in the Consolidated Order in respect to this matter, and to refuse either assistance or medicine until an "order" is produced. When this comes to be known as the undeviating rule of a medical officer, the poor in his district will hasten to take measures to secure orders for the doctor sufficiently early in a case for his services to be of some avail. It is, of course, too obvious to need remark that when a medical officer first refuses his aid, and then gives a certificate of death, he stultifies his own policy. No medical man who has not seen a case during the lifetime of the deceased person can legally or rationally certify the cause of death.

THE MANCHESTER HOSPITAL SUNDAY FUND.

THE sum raised this year by the Hospital Sunday Fund is £6557 16s. 3d.; that by the Hospital Saturday Fund £1696 9s.; in all £8254 4s. 3d. This is a very respectable sum, which must materially relieve the minds of those who have to find ways and means in hospitals. Of course there is some criticism of details of distribution. One writer in particular, "Justitia," complains in the *Manchester Guardian* that half of the money collected is given to the Infirmary, having 20,000 patients; while the insignificant amount of £302 19s. 1d. is given to St. Mary's Hospital, having 15,000 patients. These awards seem so unequal that we do not doubt there is some inaccuracy or injustice in the statement of "Justitia." At the annual meeting of the Fund some discussion arose as to the operation of the law in regard to the recommendations allowed for the grants from the Fund. One institution complained that the recommendations exceeded in money value the amount of the award. A resolution was passed to the effect that in future awards be made on the condition that the recommendations issued to the committees of Hospital Sunday shall be equal to at least 75 per cent. of the grants made. "Justitia" thinks that even this rule might operate harshly; and undoubtedly the point is one that requires discussion.

THE DISSOLUTION OF THE QUEEN'S UNIVERSITY.

IT looks very much as if Mr. Gladstone, in addition to the heavy Irish problems with which he will have to deal, must reconsider the question of higher education in Ireland. *The Times*, of Dec. 10th, gives a long report of an interview at the Viceregal lodge, on behalf of the Prime Minister, between a deputation representing the Convocation of the Queen's University and the Lord-Lieutenant. The deputation dwelt especially on the erroneous statements of Lord Cairns to the effect that the university was only an examining body. On this misconception, it was maintained, the University Education (Ireland) Bill had been passed. The deputation begged that the clauses of the Bill abolishing the Queen's University should be altered. The Lord-Lieutenant promised consideration, and reminded the deputation that there was no immediate prospect of the extinction of the university, for after the granting of the charter for the new university in Ireland two years must elapse before the extinction of the Queen's.

THE SHEFFIELD POISONING CASE.

MARY ANNIE WILMOT, the nurse from the Sheffield Nurses' Home, who was lately charged before the magistrates with administering poison to Mrs. Eliza Booth, the wife of Mr. W. H. Booth, M.R.C.S., has been committed for trial. The bare facts of the case—the sudden and suspicious death of Mr. Booth, jun., and Miss Booth, on the 8th and 16th of October, and the dangerous illness of Mrs. Booth on the 21st, with all the symptoms of narcotic poisoning, and the discovery of morphia (which had not been prescribed by any medical man) in the contents of Mrs. Booth's stomach—are familiar to our readers. Comment upon these and other facts connected with the case is impossible while the trial is pending; and we therefore defer any remarks until the facts have been re-delivered and argued upon before a higher tribunal.

ANTI-VACCINATION.

PROFESSOR F. W. NEWMAN, writing at the request of his friends (?) to the recent International Anti-Vaccination Congress at Paris, begins a letter to the Congress by observing, "I have no special acquaintance with small-pox, or with what is called vaccine." He then proceeds to dogmatise on

both small-pox and vaccine in a fashion which should have rendered the first statement superfluous. But it is useful to have the professor's own authority as to the extent of his knowledge respecting matters of which he has not hesitated to speak so freely.

PATHOLOGICAL SOCIETY OF LONDON.

THE Debate on Rickets will be resumed and concluded on Tuesday next, December 21st. Dr. Barlow and Mr. Shattock will show specimens of so-called Fœtal Rickets, and among others Mr. Lucas, Dr. Baxter, and Dr. Longhurst are expected to take part in the discussion, which will be closed by Dr. Hilton Fagge. As on the two previous evenings, some living and other specimens will be exhibited.

IN reference to a paragraph which appeared in our last issue (p. 951), we are asked to publish the following:—"At a meeting of the medical students of the Queen's College, Cork, held on the 10th inst., Mr. H. Sinclair in the chair, it was unanimously resolved, 'That we, the medical students of the Queen's College, Cork, feel it our duty to contradict the statement contained in a resolution which appeared in the *Herald* and *Constitution* of the 6th inst. expressing disapproval of Professor Charles's conduct towards two graduates of Dublin University. We consider that the entire circumstances occurred through a misconception, for which Professor Charles was in no way to blame: and we hereby convey to Professor Charles the expression of our extreme regret that any misunderstanding should have arisen.'"

LIEUT. EDWARD E. BRADFORD, R.N., specially promoted in the *Gazette* of Dec. 10th for "gallant conduct in recovering the bodies of Lieut. Bower and five seamen of H.M.S. *Sandfly*, who were murdered by the natives of the Solomon Islands," is the eldest son of Edward Bradford, F.R.C.S., of Harrow, Deputy Inspector-General of Hospitals (army), Q.H.S., and member of the General Medical Council.

A DEPUTATION, headed by Dr. McClintock, President of the Royal College of Surgeons of Ireland, waited on the Lord-Lieutenant on Saturday last, to ask his Excellency to urge on the Government the advisability of establishing in Dublin a veterinary college for Ireland. The Lord-Lieutenant promised his assistance in the matter.

THE last advices report sporadic cases of cholera to be still cropping up at some stations in Northern India. At Peshawur, Jhelum, Lucknow, Fyzabad, and Lundi Kotah in the Khyber, a few cases occurred early in November. The cold weather having regularly set in, the authorities do not anticipate any extension of the disease.

By a run-away cab-horse in Plymouth, on Saturday last, Mr. E. M. R. Rendle, M.R.C.S., narrowly escaped serious injury, whilst a solicitor with whom he happened to be conversing at the corner of a street was unfortunately killed by a splinter of the cab entering the right eye and penetrating the brain.

IT is stated that attempts are about to be made to acclimatise the chinchona in Italy, so as to increase the supply and lessen the cost of its manufacture, which is an important branch of Italian industry, and has been carried on at Milan and Genoa since 1870.

AT the suggestion of Dr. de Lanessan, the Municipal Council of Paris have decided to establish a mortuary in each of the cemeteries, where the poor, who have insufficient lodging, will be enabled to place the bodies of deceased relatives.

AT Leicester another death from "woolsorters' disease" is reported. The workmen employed in dressing the fabrics are agitating to get imported foreign wools steamed at high temperatures before being submitted to manufacturing processes.

MR. BRIGHT, M.P., Lord Rector of Glasgow University, has appointed Dr. Cameron, M.P., as his assessor.

AT its last meeting M. Brouardel was elected member of the Academy of Medicine of Paris.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Finchley.—The medical officer of health (Dr. Jas. Thurle) for the urban sanitary district of Finchley sends us his annual report for 1879. It is a very elaborate document, and, being the first annual report, Dr. Thurle has held it desirable to enter at considerable length into the reasons which govern his advice to the Authority, and his own action in the execution of his duty. His report, therefore, forms a sort of treatise on sanitary work, as well as report of proceedings during the year 1879; and it will no doubt prove, as it ought to do, most instructive to the residents and rate-payers. He gives the birth-rate of the district during 1879 as nearly 31, and the death-rate as about 12½, per 1000 inhabitants. We shall look with interest for Dr. Thurle's further reports on the district.

Lewisham.—Dr. Wilkinson reports for the year 1879 in this district a population of 67,084, occupying 10,908 houses, a birth-rate of 31·39 per 1000 inhabitants, and a death-rate of 14·35—"a lower death-rate than that registered during the previous year, and a lower death-rate than the average of England and Wales or the metropolitan districts." No particular event appears to have disturbed the even course of the health-administration of the district during the year; but we are glad to learn that the Sanitary Authority possesses an infectious disease hospital, well situated, with a resident nurse, and ambulance-waggons stationed at Lewisham and Penge.

ENTERIC FEVER AT WORTHING.

The medical officer of health for Worthing, Dr. Charles Kelly, has recently presented to the Local Board of Health a report on the prevalence of enteric fever in that town since August last of exceptional interest. Two outbreaks of the disease have occurred within that period, each under widely different circumstances. In the first outbreak, which happened during the months of August and September, the cases occurred in a circumscribed locality under very defective local sanitary conditions, and at a time when a very heavy rainfall rapidly filled the sewers, driving the sewer-air back through imperfect places, there being no ventilators in the locality to relieve the pressure. In this way the sewer-air was forced into the infected houses, and to this is attributed the first outbreak. A second outbreak of enteric fever presently followed, beginning in October, but under entirely different circumstances. Neither defects of drainage nor of water-supply yielded any explanation of this second outbreak, but it was quickly ascertained that the victims were all consuming milk from one source. This clue obtained, Dr. Kelly was enabled to follow it until he lighted upon a clear explanation of the origin and spread of the disease. He traced it to the milk of a particular dairy, in which the water used for dairy purposes came from a well which had unquestionably been polluted with the discharges from a patient suffering from enteric fever, a sporadic case, shortly before the outbreak. The history of the outbreak, and of its relation to the milk-supply, and of this supply to the well-water and the pollution of the latter, is very complete, and forms one of the best of the more recent examples that have been recorded of the

dissemination of the infection of enteric fever through a milk-supply.

THE LOWER THAMES VALLEY SEWERAGE.

At a recent meeting of the Lower Thames Valley Sewerage Board a member observed that the Board had not got a spade, a pickaxe, or a drainpipe for the £30,000 it had spent. We are glad, however, to learn that each of the sanitary authorities represented on the Board will receive a copy of the evidence given at the late inquiry. The Chairman remarked that it would probably be the only value the authorities would get for their money; as if the *experience* gained went for nothing!

THE SEWERAGE OF GUILDFORD.

The Local Government Board has been writing to the Sanitary Authority of Guildford asking what they propose to do about the sewerage of the town. But the Authority objects to being hurried in considering the question, as it is only ten years ago since a Government engineering inspector pointed out the necessity for sewerage, and only twenty years ago that the local Authority began to think that it was time to begin to think about the matter!

The Chelmsford Rural Sanitary Authority have issued a series of regulations and suggestions, prepared by their medical officer of health, Dr. Arthur Downes, on "The Proper Construction of House Drainage," "As to House Fittings, &c., for Water-supply, &c.," and on "Preventing the Spread of Infectious Diseases," admirably calculated to effect the objects they seek to attain. It is astonishing the amount of useful, practical information which may be diffused in this manner, conveyed in a way which is brought home to the head of a family. Dr. Downes and his Authority are both to be congratulated upon the good example they have set in this matter.

It is the intention of the Hackney guardians to ask the sanction of the Central Board to the establishment of a sanatorium at the seaside for pauper children under the management of the Asylums Board. The cost of the proposed home is mentioned at £50,000, to be defrayed out of the Common Poor Fund.

The Local Government Board have signified their consent to a proposal to erect an infectious disease hospital for the use jointly of Rochester and Chatham. The site chosen for the building is, we are informed, situated not far from the military hospital at Fort Pitt.

Given a specimen of water which, the chemical analysis being accepted on both sides, and both sides consisting of medical officers of health and chemists, the one side says it is *unfit* for domestic purposes, the other side it is quite *fit* for domestic purposes, what is to be done?

A deputation of the Town Council of Edinburgh has recently visited Glasgow for the purpose of studying the arrangements made there for the isolation in hospitals of infectious diseases.

A public meeting held at Leicester has protested against the appointment of additional vaccination officers for that town, and thanked Mr. Taylor for his motion in Parliament against compulsory vaccination.

Deputations representing the alkali manufacturers of the United Kingdom and from Leicester, appointed by a public meeting concerning river-floods, had interviews on the 11th inst.

Richmond (Surrey) is contemplating making a new well, at a cost of £10,000, to add to the water-supply.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Under the influence of the unseasonably mild weather, English urban mortality showed a further decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5125 births and 2882 deaths were registered last week. The births were 60, and the deaths 393, below the average weekly

numbers during 1879. The deaths showed a further decline of 79 from those returned in recent weeks; and the annual death-rate per 1000, which had been equal to 22.1 and 20.6 in the two preceding weeks, further declined to 20.1 last week, a lower rate than has prevailed in any week since the middle of July last. The lowest death-rates in the twenty towns last week were 15.9 in Sheffield, 16.7 in Plymouth, 17.3 in Leeds, 17.5 in Portsmouth, and 18.2 in Norwich. The rates in the other towns ranged upwards to 21.6 in Hull, 22.8 in Manchester, 24.3 in Liverpool, and 27.2 in the borough of Salford. During the first ten weeks of the current quarter the death-rate in these twenty towns averaged only 21.8 per 1000, against 22.7 in the corresponding period of the four years 1876-79.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 405 and 358 in the two preceding weeks, were 370 last week; they included 140 from scarlet fever, 70 from whooping-cough, 69 from measles, and only 33 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2.6 per 1000 in the twenty towns; no death from any of these diseases was recorded either in Norwich or Plymouth, whereas in the other towns their death-rate ranged upwards to 4.5 in Sunderland and 6.2 in Salford. The fatal cases of scarlet fever in the twenty towns, which had been 162 and 139 in the two previous weeks, were 140 last week, and showed the largest proportional fatality in Sunderland, Bristol, Salford, and Liverpool. Measles fatality was again largest in Salford, and that of whooping-cough in Hull, Liverpool, and Birmingham. The highest death-rate from fever, principally enteric, was recorded in Leeds. Of the 12 deaths from diphtheria 8 occurred in London. Small-pox caused 12 more deaths in London, and one in Liverpool; whereas no fatal case of this disease was recorded in any of the other eighteen large provincial towns. Judged by the hospital returns, the prevalence of small-pox in London showed a further marked increase last week. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had increased steadily from 77 to 246 in the six preceding weeks, further rose to 338 last week. The number of new cases of small-pox admitted to these hospitals, which had been 99, 57, and 67 in the three previous weeks, rose last week to 132, and exceeded the number of admissions in any week since May, 1878. The number of patients in the Highgate Small-pox Hospital also showed a further increase last week, and were 30 on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 367 and 334 in the two preceding weeks, further declined to 295 last week, and were no less than 202 below the corrected weekly average; 169 resulted from bronchitis, and 78 from pneumonia. The annual death-rate from lung diseases was equal to 4.2 per 1000 in London, and 5.4 in Liverpool.

In the twenty towns last week 69 deaths were registered without the production of the certificate either of a registered medical practitioner or of a coroner; these were equal to 2.4 per cent. of the total deaths registered. The proportion of uncertified causes of death did not exceed 1.2 per cent. in London, whereas it averaged 3.5 per cent. in the nineteen provincial towns. No uncertified causes of death were registered last week in Portsmouth, Norwich, or Plymouth, whereas their proportion was largest in Wolverhampton, Salford, and Oldham.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 21.7 per 1000, against 24.7 and 22.1 in the two preceding weeks; it was 1.6 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 15.6 and 19.1 in Perth and Dundee, to 23.4 and 28.7 in Leith and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 112 and 95 in the two previous weeks, further declined to 91 last week; they included 33 from scarlet fever, 18 from diarrhoea, 13 from whooping-cough, 11 from diphtheria, 8 from fever, 8 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 3.7 per 1000 in the eight towns, and exceeded by 1.1 the average rate from the same diseases in the twenty English towns. In the eight Scotch towns the zymotic death-rate

last week ranged from 1.7 and 2.0 in Dundee and Aberdeen, to 6.4 and 9.8 in Paisley and Leith. The fatal cases of scarlet fever in the eight towns, which had declined from 53 to 34 in the four preceding weeks, were 33 last week, of which 23 occurred in Edinburgh and Leith, and 9 in Glasgow. The 13 deaths from whooping-cough showed an increase upon the number in the previous week, and included 7 in Glasgow. Eight of the 11 fatal cases of diphtheria were also returned in Glasgow. The 18 deaths from diarrhoea showed a further increase upon recent weekly numbers, and a marked excess upon the average for the season; 7 occurred in Glasgow, 3 each in Edinburgh and Paisley, and 2 each in Aberdeen and Perth. The 7 deaths from fever (including typhus, enteric, and simple) showed a decline from those in the previous week, and included 4 in Glasgow, 2 in Edinburgh, and 1 each in Paisley and Leith. The deaths referred in the eight towns to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy), which had been 166 and 155 in the two preceding weeks, further declined to 128 last week. The annual death-rate from these lung diseases was equal to 5.2 per 1000 last week in the eight Scotch towns, against 3.6 in London; the highest death-rates last week from these diseases in the Scotch towns occurred in Leith, Paisley, and Greenock.

HEALTH OF DUBLIN.

There was a further considerable decline in the Dublin death-rate last week. The annual rate of mortality from all causes in the city, which had declined in the four preceding weeks from 39.6 to 29.8, further fell last week to 27.2, a lower rate than has prevailed in any previous week of this year. During the first ten weeks of the current quarter the death-rate in the city averaged, however, 33.6 per 1000, against 21.2 in London, and 22.2 in Edinburgh. The 164 deaths in Dublin last week showed a further decline of 16 from the numbers returned in recent weeks, and included 18, or 11 percent., which were referred to the seven principal zymotic diseases, or 10 less than those in the previous week; 8 resulted from fever (including typhus, enteric, and simple), 6 from scarlet fever, 3 from whooping-cough, one from diarrhoea, and not one either from small-pox, measles, or diphtheria. The annual death-rate from these zymotic diseases was equal to 3.0 per 1000 in Dublin last week, against 4.5 in Edinburgh. The deaths referred to fever, which had been 17 and 10 in the two preceding weeks, further fell to 8 last week, but still showed a marked excess compared with the proportional fatality of fever in the twenty large English towns. The 6 deaths from scarlet fever in Dublin last week also showed a decline from the numbers in recent weeks, while the 3 fatal cases of whooping-cough corresponded with the number in the previous week. The deaths of infants in the city were fewer than in any previous week of the year, and those of elderly persons also showed a decline.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

SMALL-POX IN LONDON.

In London, according to the Registrar-General's Weekly Return, 12 fatal cases of small-pox were registered last week. This number is small, and it appears that it is 16 below the average number in the corresponding week of the last two years, in several of which small-pox was epidemic in the metropolis. When, however, we note the hospital returns, it is no longer possible to deny that there are grave indications of a very serious increase of small-pox prevalence in London. The Metropolitan Asylum Hospitals contained but 77 small-pox patients on 23rd October, to which number they had pretty steadily declined from 237 at the end of June. Early in November the small-pox admissions, and the cases under treatment began to increase, and after the middle of that month this increase became rapid. On Saturday the 11th inst. the cases under treatment in these hospitals had risen to 338, a higher number than on any day since May, 1878. The number of new cases admitted to these hospitals, which had been 99, 57, and 67 in the three preceding weeks, rose last week to 132, of which 61 were admitted to the hospital at Deptford, and 45 to that at Homerton. It is unsatisfactory to note that of the 12 fatal cases of small-pox registered in London last week, 5 were of children aged between one and five years, affording conclusive evidence of neglected or ineffi-

cient vaccination. The deaths of children from small-pox under our present compulsory vaccination laws speaks forcibly of evasion of the provisions of those laws, especially mischievous because this failure is used by anti-vaccinators as an argument against such laws. With regard to the naturally increasing proportion of adult victims of small-pox the remedy is not so simply provided, as revaccination at adolescence, however strongly recommended, is but very partially resorted to among the classes who are most exposed to infection during epidemic periods.

SEWER VENTILATION AT LEITH.

At a recent meeting of the Leith Town Council, Provost Henderson, *à propos* a memorial from certain inhabitants on nuisance said to be caused by the sewer ventilation in the streets, took occasion to address the Council on the principles and practice of sewer ventilation. He described the various means which had been resorted to in different towns to secure ventilation of the sewers, by in-draughts, by out-draughts, by furnaces, by screws, but thought experience had proved that the simpler the means adopted the more effectual the result. In fact, the more numerous and more direct the openings made in the sewers the better the ventilation and the less the nuisance (if any) from sewer air. He, as Mrs. Lirriper with the chimney-cowls and smoke, preferred the ventilation, and the means thereof, plain, and this was the general conclusion of competent observers on the subject. If the street ventilators of Leith stink, the evil must be sought, not in the ventilators, but in the sewers themselves.

THE PUBLIC HEALTH SOCIETY OF ST. PETERSBURG.

The general meeting of the Public Health Society of St. Petersburg was held on the 28th ult. Dr. Zdeckawer, the president, announced that the Minister of the Interior had granted 2000 roubles to the funds of the Society, and that sanction had been obtained for the establishment of branches at Odessa, Kazan, and Theodosia. General Count Loris Melikoff and others were elected honorary members of the Society. Professor Zdeckawer was re-elected president, and Professor Andrievsky was elected vice-president in place of M. Obroutchew, who retires. The Society has 296 members and an income of 1875 roubles. The expenses to the 12th November last had been 1868 roubles, of which sum 1600 roubles had been absorbed in rent, but there is hope of this expense being largely diminished by the Society obtaining permanent rooms.

The French Society of Hygiene passed a resolution at its last sitting, that it was desirable that a canal be constructed from Paris to the sea, in order to discharge on the coast the contents of the sewers, and that this should also receive the offal and night soil of the capital.

THE SERVICES.

THE AFGHAN GAZETTE AND DESPATCHES.

The following addendum has just been made to the Gazette publishing the despatches relative to the campaign in Afghanistan:—

"The names of the following medical officers having, through an oversight, been omitted from G.O.C.C., Oct. 14th, 1879, his Excellency the Commander-in-Chief, with the concurrence of the Viceroy and Governor-General in Council, is pleased to direct that, in recognition of the valuable services performed by those officers, their names be added to the list contained in Par. 6 of the above order:—*Kuram Field Force*.—Surgeon-Major G. Farrell, Indian Medical Service, in charge head-quarters staff; Surgeon-Major C. P. Costello, base hospital, Kohat, afterwards Kuram. *Southern Afghanistan Field Force*.—Surgeon-Major R. W. Cunningham, M.D., base hospital and charge of Commissariat, Kandahar Citadel; Surgeon-Major B. Thompson, M.B., Indian Medical Service, base hospital, Quetta.

Deputy Surgeon-General J. L. Jameson, Army Medical Department, has been appointed to succeed Surgeon-General Thompson as Principal Medical Officer at Cork. Deputy Surgeon-General Jameson has recently arrived home from India on promotion.

The undermentioned medical officers have retired from the army, and have been placed on retired pay:—Surgeons-Major Charles William Griffith, Hunter Alexander Colan, Benjamin Hinde, M.D., and John Alfred Illingworth, Medical Department, with the honorary rank of brigade surgeons.

The Indian troopship *Jumna* has arrived at Portsmouth from Bombay, which place she left on Nov. 8th. She brought home Surgs.-Major Tippetts, Palmer, Howard, and Nicholson, Surgeons Webb and Carter, of the Army Medical Department, and Surgeons Worgan and Earle, of the Indian Medical Department.

ADMIRALTY.—The following appointment has been made: Surgeon George C. Goding to the *Helicon*.

GUY'S HOSPITAL REFORM.

A PUBLIC MEETING was held on Wednesday night at the Bridge House Hotel, London-bridge, "To consider what steps are desirable to be taken with reference to the present unsatisfactory position of this great institution."

Mr. Arthur Cohen, Q.C., M.P., presided, and in opening the proceedings said that Guy's Hospital was, perhaps, the greatest and most important institution in the borough of Southwark, having been founded about 150 years ago. Since that time it had been enlarged and improved at an expenditure of something like half a million of money, and had afforded help and relief not only to the people of Southwark, but to those living in distant parts. In connexion with it a large and important medical school had been founded, a school of which the country was justly proud, and which formed a noble model for other countries to copy. He could not deny that there existed among the public at the present time a profound dissatisfaction at certain matters which had come before the public in connexion with this institution; and as the representative of the borough in the House of Commons he had felt it to be his duty to take the chair on this occasion.

Mr. A. Hawkins moved: "That this meeting deeply regrets the state of matters existing at Guy's Hospital, which has led to the resignation of two of its chief officers, and which must be most damaging to the interest of the sick poor, for whom this charity was instituted." It was because he felt that the intention of the pious donor was not being carried out at this hospital that he had ventured to join in a movement for calling attention to Guy's Hospital. Thomas Guy's idea was to found an institution where the poor and sick could be healed, but when he looked upon that grand institution at the present time he found that a large number of its beds were empty. What was the reason for this, but the fact that the funds Guy had left had been turned to an account which was contrary to his desire and expressed wish. Although Thomas Guy was a baptist, he had with the best of wishes appointed a clergyman of the Church of England to be the Chaplain of the hospital, little dreaming that the foolery of ritualism would thereby be introduced into the hospital. Such, however, had been the case. The institution was governed by a self-appointed body, and the matter must be looked into, and the light of public opinion brought to bear upon it.

Mr. John Berry seconded. There was a time when he had been glad to take his children when in sickness to receive the excellent advice provided at the hospital, but he should be sorry to do so now. Jealousies had been allowed to grow up to the injury of the poor; and a few were reaping the benefit of the institution to the detriment of the many. Such crying evils as now existed must not be allowed to continue.

The resolution was adopted.

Mr. Robins moved: "That Parliament be petitioned for the appointment of a Royal Commission to inquire into and report as to the present system of governing Guy's Hospital with a view to its being placed upon a more desirable and responsible basis, and that the Borough members be asked to support the petition." While admitting the propriety of establishing some one to act as chaplain to the hospital, he contended that the religious element was secondary to the

curing of the sick. A sisterhood had been introduced to the displacement of the old nurses, who were mothers in the hospital, and the garb of the former, he was assured, operated badly with the patients, for instead of being hopeful of recovery, they were impressed with the idea, created by the dress of this new order, that they were to be prepared for another world. He did not speak against the sisterhood, but they were out of place at Guy's Hospital. Forty years ago the Charity Commissioners inquired into the government of this charity, and they condemned the practice of so much power being given to one official—the treasurer. He could remember when two of the wards would have been shut up but for the subscriptions of the doctors, while at that very time no less than £3000 was spent in decorating the house of the treasurer. As a member of the Metropolitan Asylums Board, he might say that his board never thought of entrusting the management to any but the doctors in charge of the patients at their hospitals. They had full and absolute control. But at Guy's the doctors were pushed on one side, and the sisters interfered to such an extent that the former could not put up with it any longer.

Mr. J. Mitson seconded, and the resolution was agreed to.

The Rev. G. M. Murphey moved: "That in the opinion of this meeting it is desirable that every Board of Guardians, Vestry, and District Board in Southwark should have one or more representatives on the committee of management of this hospital." He contended that the affairs of the institution needed properly auditing by an independent and competent party.

Dr. Freston seconded. He was told that the institution was £17,000 behindhand; this needed looking into. As a medical man, he maintained that the sick poor of Southwark ought to have that which was their perfect right to enjoy.

Dr. Burton said that, as very kindly remarks had been made concerning the doctors, he thought the resolution ought to provide for a certain number of their profession being on the Board of Management—that an efficient physician and an efficient surgeon should be on the Board. That would be the least act of courtesy which could be extended to the medical staff.

The Chairman said he had spoken to many intelligent men and women upon this point, and they had said it was a most strange circumstance that not a single physician or surgeon was on the board of governors. He (the speaker) felt he should only be expressing the feeling of this meeting when he urged that the medical staff should be represented on the management.

The resolution, amended as suggested, was then unanimously agreed to.

Mr. Andrew Dunn moved that a deputation of the meeting should wait upon the Home Secretary, to urge him to present their petition to Parliament for a Royal Commission. This was adopted, and the proceedings closed in the usual manner.

Correspondence.

"Audi alteram partem."

ON MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—The question of medical education, which you have just reopened, deserves all the consideration which the profession can give to it. After the teachers, examiners, and other celebrities of the metropolis have spoken their word, may a provincial physician venture to relieve his mind upon a portion of the subject which, so far, has not attracted all the attention which, in my opinion, it deserves? I allude to the neglect of apprenticeship, or pupilage, in these days, especially in relation to our provincial hospitals. Your own comments upon Mr. Savory's letter (THE LANCET, Dec. 4th) contains the germ of what, with your permission, I would further develop. You have touched the question of apprenticeship or no apprenticeship very gently, as if fearing to arouse a controversy thereupon; but I would suggest that the question of the best mode of initiating our students into

medical life cannot be properly argued without hearing what apprenticeship has to say in its own behalf.

But going back for a moment to your comment upon Mr. Savory's letter, you say that the remedies for our present difficulties are threefold—first, diminution of the number of subjects studied; secondly, diminished proficiency in present subjects; thirdly, lengthened time to fulfil the present curriculum.

Admitting that it is out of the question to lower the standard of the pupil's knowledge, we are reduced to the first and the last as alternatives. I would suggest, however, that both of these are open to adoption—viz., lessened number of subjects, and lengthened period of study. No doubt the arguments of the teachers in behalf of their individual subjects are not easily assailable, yet there is one idea in connexion with them which I find seldom alluded to. Surely these various subjects, allowing each of them to be necessary to a complete medical education, must have relative degrees of importance, the dicta of said teachers notwithstanding. No one, not himself a teacher, will pretend that an extended acquaintance with botany, chemistry, materia medica, or even medical jurisprudence, is as indispensable to the student as a knowledge of anatomy, physiology, medicine, surgery, and midwifery—the five pillars of the temple of medicine! Why, then, should it be thought necessary that the examinations in each of these *two sets* of subjects should be equally stringent, and the student's acquaintance with them equally complete? In fact, is there not a fundamental error in the methods of examination as now conducted by at least some of our licensing bodies? The same cut-and-dried subjects being set for all, proficiency is expected in all of them from each candidate, for your examiner is as jealous as your teacher for the status of his own subject.

Now, medical students vary in the bent of their minds as much as in industry or ability; yet no allowance is made for this. We know that some young men have great difficulty in producing their knowledge, although they may be full of it, and keenly bent upon progress. Others, quick and shallow, may, by means of cramming and diligently studying the idiosyncrasies of examiners, make a much greater show of knowledge upon all subjects submitted to them. I contend that one object of all examinations should be to find out what there is in a man; in what direction his mind will develop—whether towards the steady and honest acquisition of sound knowledge, or whether it is set upon those flashy and taking subjects which he thinks will obtain for him the reputation of being a clever fellow. It would, then, follow that excellence in the greater subjects and an evident disposition to acquire knowledge honestly should excuse a somewhat deficient acquaintance with botany and kindred subjects. Yet there is no need that even these should not have their share of attention.

The extension of time, which, in one way or another, is generally allowed to be desirable, if not essential, to an improved education, will be the means of overcoming the difficulty. How shall that extension be made? I think by means of reviving apprenticeship, or at least pupilage, and making it compulsory upon all students except those who proceed to a university for their medical education.

The neglect into which the old-fashioned apprenticeship has fallen doubtless followed upon improvement in the means of communicating medical knowledge at the schools. The bottle-washing, shop-cleaning apprentice has gone the way of the old-fashioned apothecary. Forty years ago the apprenticeship of five years to an apothecary was in full force. To these five years were added two for "walking the hospitals"; in all seven. Afterwards attendance at the schools was extended to three years, and then the five years' apprenticeship was virtually reduced to three—making in all six. This is about the period Mr. Savory would have the student devote to medical study at the schools. But is there any prospect that a sufficient number of young men would or could devote this number of years, with its increased expenditure, to a medical education in a metropolis? The expense would deter most men, and in the few cases where the command of money might clear this obstacle, would not the possession of means result in the first years being spent in idleness or something worse?

Twenty years as physician to a county hospital have shown to me the grievous waste of educational means which such institutions display. What unrivalled opportunities of acquiring a general knowledge of disease and of patients, of nursing and dressing, are here neglected and despised! It

has fallen to my lot to see a good many young fledglings fresh from the schools. Not one in four of them, when brought face to face with the work of a hospital—the minor operations of surgery, the dressings and manipulations—has known how to draw a tooth deftly, pass a catheter safely, or dress a bed sore without torturing the patient. But they could talk glibly enough of the difference between tubular and interstitial nephritis, or antero, or postero, or insular spinal sclerosis, &c. &c. They are, in fact, alike ignorant of the value of what they have missed and incapable of remedying their loss.

It has been said that the time for acquiring this *practical* kind of knowledge is after the student has learned the *theory* at the schools. But not so. So soon as he has got the document in his pocket which, and not the mere acquisition of sound medical knowledge to guide him in after-life, has been the sole object of his endeavours, he is off to remunerative work—to an assistantship, to partnership, or perhaps the public service, and his defects are discovered when he is found to be unable to bleed a patient with safety, or set a fracture rightly.

Pupilage is an entirely different thing now to what it was in the days gone by. Our youths are now better educated, and would not submit to the drudgery of the surgery or the shop. Besides the various county hospitals, large work-house infirmaries, &c., many practitioners in large practice amongst the working classes, mines, unions, &c., are able to give the pupil invaluable opportunities of learning to *see* and learning to *handle*. Formerly large sums were paid for these advantages, now so unaccountably neglected. Three hundred pounds was frequently paid for the privilege of being considered the pupil of a hospital surgeon. Much more moderate sums now suffice, and I believe that the cheapest way of passing the first two years of the student's life would be to become the apprentice or pupil of a general practitioner.

But more than this. The most important point remains to be noted. We are all agreed that such subjects as botany, chemistry, and *materia medica* should be learnt, and an examination passed in them, *before* the commencement of regular hospital studies. These two years of pupillage would afford the best of all trials for these subjects. There is scarcely now a town of any pretensions which has not science classes and private teaching in such subjects as chemistry and botany. *Materia medica*, separate from therapeutics, can be taught in the surgery, or in the chemist's warehouse. Thus, the first batch of the student's work would be got over before all his energies are required for the graver studies at the schools. The work, too, under the supervision of his master, would keep the pupil out of idleness, and give him a zest instead of a disgust for his anatomy and physiology. To sum up, I would suggest that five years be made the minimum for the student's education; that two of these should be compulsorily passed as a pupil at a hospital, dispensary, or with a general practitioner in large practice; that the examination in botany, chemistry, and *materia medica* (also physics and zoology where they are required) should be passed absolutely before the commencement of the regular work of the medical school, for which three full years should be allotted.

I cannot imagine any real objection to this plan. It has the advantage of cheapness over what five years spent in the metropolis would cost. It lengthens the time for acquiring strictly medical knowledge, and keeps the pupil employed during the whole of it. But this or any other plan would fail of its object if the various boards will not recognise the necessity for agreement amongst themselves as to the requirements of medical education, and abstain from any of those arts by which it is sought to gain selfish advantage the one of another.

I am, Sir, your obedient servant,

WILLIAM STRANGE, M.D.,

Worcester, Dec. 13th, 1880. Physician to the Worcester Infirmary.

To the Editor of THE LANCET.

SIR,—I have read with considerable interest the letters on the above subject now appearing in THE LANCET, and, with your permission, I would make a few remarks on one or two of them, especially that of Mr. Butlin. Mr. Butlin cannot see the use of botany, and other subjects. Now, Sir, I do not agree with those examiners who seem to expect from

the student a profound knowledge of botany and zoology, &c., but I do not think that it requires much thought to arrive at the conclusion that these subjects are of use to the student of medicine. If our students were required to undergo a sound training in arts and the natural sciences before beginning their studies, botany, &c., might be eliminated from the medical curriculum. The study of botany, if it does no other good, at least trains the student to think, and to observe and arrange facts. If we were only to learn what *may* be of immediate use to us, how ignorant we should all become; but who knows what may be his future life? In my lectures, in reply to the question "What is the good of natural history?" I am in the habit of quoting the case of M. Bergeret (*Ann. d'Hygiène*, 2ème, sér. iv. p. 442), where a knowledge of the metamorphosis of insects led to the discovery of a case of infanticide. Mr. Christopher Heath's suggestion is most important. There are students here, as elsewhere, who waste their first two years of study, their great ambition being to get in their "cards" for lectures, and then at the last grind up for *all* the subjects. This state of things would be obviated if the suggestion of Mr. Heath were carried out. The cry of students of "no time" is only an excuse for idleness. I never knew an idle man who did not make the same excuse. The busiest men find time to write novels while carrying on the affairs of the country. I hope that Mr. Butlin does not wish to educate men *down* to the poor remuneration some of us receive for our services. His letter would lead one to think that the game was not worth the candle.

I am, Sir, your obedient servant,

H. AUBREY HUSBAND, F.R.C.S.E.,

Lecturer on Medical Jurisprudence and Public Health,
Medical School, Edinburgh.

Northumberland-street, Dec. 11th, 1880.

To the Editor of THE LANCET.

SIR,—There is some hope for the future of medical education when examiners, teachers, and students alike proclaim their dislike and distrust of the present system.

Whatever exceptions may be taken to Mr. Savory's proposal to extend the period of education to seven years, everyone must agree that the amount of work now prescribed cannot be properly mastered by the majority of students in four years. But I venture to suggest that a considerable part of our difficulties is the result of the deficient education of so many students before the medical curriculum commences.

It is not the student who has a first-class or even moderate education, be it classical or scientific, that finds a difficulty in passing his examinations. The main bulk of failures are to be found among such students as, after passing through a routine education, arrive at hospital unable to write or even spell their own language correctly, whilst their knowledge of Greek or Latin will not suffice to teach them the derivation of anatomy or to understand the meaning of the word "circumflex." As for their knowledge of natural science, it is absolutely *nil*; they do not know that bodies expand by heating, and such phenomena as atmospheric or fluid pressure, the force of gravity, the refraction of light, or the rudimentary truths of chemistry, are subjects they have barely heard by name, and can form no conception of. What wonder then, if the teacher finds it difficult to convey to their minds, in the short time which is allotted to him, a correct appreciation of such phenomena. As to the passage of ray of light into the eye, or the conversion of albumen into peptone, after months of work the teacher is told to his disgust that a ray of light passes into the eye *by the force of gravity*, and that peptone is a *stuff like broth*.

Improve the preliminary studies, and we shall be many steps nearer the goal of a good medical education. It is certainly not too much to ask that such phenomena of natural science as I have alluded to above should be taught the student before he commences his medical curriculum.

What part of the present medical bill of fare could with greatest advantage be omitted I will not take upon myself to say; but any omission, were it only the pisiform bone, would be welcome. It would relieve the student from the necessity of ridding himself, by a process of rapid evacuation, of the crude material which he has greedily swallowed from his teachers' lips, but which he finds

too much for his stomach when the trial of examination has passed, even if he is lucky enough to escape a violent attack of indigestion in the presence of his examiner, owing to frequent overdoses of touch corpuscles, muscle rods, or Malpighian bodies.

I remain, Sir, yours obediently,

W. BRUCE CLARKE,
Assistant Demonstrator of Anatomy,
St. Bartholomew's Hospital.

December 1880.

To the Editor of THE LANCET.

SIR,—Mr. Tindal has, undoubtedly, hit the right nail on the head in his remarks on this subject. It is the difficulty of attaining a knowledge of every minute detail of anatomy in the case of the ordinary student that is the grave obstacle, and that ruins his health and constitution. But, of course, if the acquirement of this accurate knowledge is indispensable to the usefulness and efficacy of the practitioner, there is no escape but to continue the struggle, risk his life, bear the stigma attached to repeated failure, and the sickness of heart caused by hope long deferred, until after the best years of his life have passed the Primary Examination is passed; or adopt the other plan, and, which under the circumstances appears the wisest, throw up the business at the onset. Of course, this picture represents only the case of the ordinary student, and it is only the requirements of the ordinary student that demand consideration. But what is the number of ordinary students, and who are they? Is it not a fact that they amount to three-quarters of the whole number who are registered as such? Is it not known that more than half the number ultimately are obliged to give up the attempt, and are unable to accomplish the too difficult task presented by the Primary Examination of the Royal College of Surgeons? The question is, whether this must be taken as a sign of their unfitness for practical medical work. My idea is, if a general knowledge only were required, with a special knowledge of those parts which disease and the necessity of surgical interference renders more important—such, for instance, as the relations and position of the arteries and the action of certain muscles—it would be found an efficient remedy.

I am, Sir, yours obediently,

Dec. 14th, 1880.

MEDICUS.

IRELAND.

(From our own Correspondent.)

THE Committee appointed by the Senate of the Royal University of Ireland had several meetings last week to consider the scheme for organising the new University.

On the 9th inst. a deputation of graduates of the Queen's University in Ireland waited on the Lord-Lieutenant (who was accompanied by the Chief Secretary for Ireland), for the purpose of making a protest against the proposed extinction of the Queen's Colleges in Ireland as intended under the Irish University Education Bill. Mr. Stoney explained their object, and stated that it was at the suggestion of Mr. Gladstone that they waited on His Excellency to place their views before the Irish Government. The Irish University Education Bill of last session was substituted for The O'Connor Don's Bill, and no communication had been made respecting it to the graduates or Senate of the Queen's University, a course entirely without precedent. Lord Cairns, in introducing the Bill, represented their University merely as that of an examining body, which was an entire misapprehension, as the Queen's was perhaps the most academical University of its character in the United Kingdom, and its examinations were framed so as to encourage sound learning. The Queen's University had rendered great educational services to the country, and it was submitted that it would be a very serious thing, in dealing with the education of Ireland, to blot out the work of thirty years, which had brought about a thoroughly sound system of education. The dissolution of such a university would involve great loss to its graduates, and the deputation thought it deserving of the careful consideration of the Government whether the clauses of a Bill introduced under misapprehension, and which would produce such grave effects, should be allowed

to pass. Various graduates, medical and other, urged the same views, and His Excellency, Earl Cowper, in reply said, that there was no doubt that the Queen's University had done good work, but, on the other hand, it would be very difficult for the new Royal University to exist side by side with it. He promised to communicate their views to the Premier, reminding the deputation that there was not a very immediate threat of dissolution, as they had a year and a half yet before them.

At a meeting of the Senate of the University of Dublin, held last Saturday, a grace was submitted from the Provost and Senior Fellows, that the degree of Doctor Utriusque Juris be conferred (*honoris causa*) on General Sir Frederick Roberts, G.C.B., and was passed unanimously.

At a monthly meeting of the Governors of Mercer's Hospital, Dublin, held last week, it was stated that in consequence of the larger number of patients maintained in the hospital since the opening of the additional wards in the new wing in 1878, the annual expenditure had exceeded the yearly income. The result is, that a balance is due to the bank of close on £900, and that the governors have been obliged to reduce the number of beds occupied.

On last Monday a deputation from the Dublin Obstetrical Society waited on the Lord-Lieutenant for the purpose of requesting His Excellency to influence the Crown, so as to appoint a representative of obstetrical medicine on the General Medical Council. A memorial was presented, which showed the great necessity for a thorough knowledge of obstetrics and diseases of women, and alleged that the present unsatisfactory state of affairs might be attributed to the fact that this branch of the profession had never been represented on the General Medical Council. Dr. Byrne, President, pointed out that the Council consisted of twenty members, which were elected by the universities and licensing bodies, and by the Privy Council, but not a single member representing the obstetrical branch of medicine had been elected. Earl Cowper, in replying, said that there was no doubt the department of medicine to which they had alluded was most important, and it did not require any medical knowledge to make one aware of the fact. If the education in that branch of the profession was so neglected as it appeared to have been from what the deputation had said, it was only right that that defect should be remedied. With regard to the filling up of the vacancy caused by the death of Dr. Hudson, he would lay what they had said before the President of the Council, but it occurred to him that it would be more advisable to elect for the appointment in question a man of high standing in the profession, having a full knowledge of all its branches than an expert in the one department to which they belonged.

A grand bazaar and fancy fair will be held in the Ulster Hall, Belfast, on the 16th inst. and two following days in aid of the Belfast Royal Hospital; and a large amount is expected towards the funds of this estimable charity.

Lady Harriet Bentinck has liberally helped the funds of the Cork Home for Incurables by a donation of £3000, of which £1600 will be devoted to the building fund, thereby freeing it from debt.

A deputation from the Corporation of Dublin had an interview last week with Mr. Forster, Chief Secretary for Ireland, in reference to the compulsory notification of infectious diseases. The deputation urged the necessity of providing that the medical practitioner in attendance on a patient suffering from an infectious disease should testify the existence of the said disease to the sanitary authority. The Chief Secretary said that if satisfied it was a desirable thing to have done, he was confident the Government would render every assistance.

Dublin, Dec. 14th, 1880.

PARIS.

(From our own Correspondent.)

ON the 10th instant Dr. Debove made an important communication to the Société Médicale des Hôpitaux on Nerve-stretching for the relief of Locomotor Ataxia, and exhibited a patient who had been submitted to this treatment. The operation is of German origin, and has been introduced here on the authority of Langenbeck, Esmarch, and Erlennmeyer, who have each of them practised it in a case of ataxia with more or

less success. The history of Dr. Debove's patient is as follows:—Louis A.—, aged fifty-six. No antecedent disease. In 1874 he felt pains in both legs, which were of a darting character. Six weeks after appeared symptoms of incoördination, and simultaneously with these darting pains in the upper extremities. In the beginning of November, 1880, the condition of the patient was the following:—Every day there occur attacks of the most severe pain in both upper and lower extremities. These come on with still greater violence at night, and for several years the patient has never passed twenty-four consecutive hours without them. They are calmed by repeated injections of morphia (sixteen centigrammes daily). Every week or fortnight there are gastric, urethral, and vesical paroxysms, which add to the sufferer's tortures, and generally last some days. The ataxy is limited to the lower extremities, but is so considerable that for eighteen months A.— has not left his bed. When he tries to rise he is unable to do so, and at once sinks to the ground; and when he endeavours to execute movements with his legs whilst lying on his back, there is evidence of motor incoördination in the highest degree. All knowledge of position is wanting, and it is only by sight or touch that A.— is able to find his legs in bed. The lower limbs are considerably wasted, and the patellar tendon-reflex is wanting on each side. In the arms the pains are the only trouble. Both pupils are myotic in an equal degree, but there is no defect of vision, and there has never been any paralysis of the extrinsic muscles of the eye. Cutaneous sensibility is deadened, especially in the legs, but there are no patches of anæsthesia on any part of the surface.

On Nov. 18th, M. Gillette, surgeon to Bicêtre, exposed the sciatic nerve in the posterior and middle part of the thigh, and stretched suddenly and violently twice. The incision was then dressed antiseptically. After the operation no motor or sensory paralysis was observed in the territory of the elongated nerve. The following day there had been no recurrence of the darting pains, only a few moderate pains in the neighbourhood of the wound, but very different to those from which the patient suffered habitually. There was also a sensation of formication, which began in the left limb, and afterwards extended to the other. On the 20th of November the pains had not returned, and cutaneous sensibility was normal. On the 1st of December a gastric paroxysm, with sensation of contraction, occurred, which lasted until the 4th, but, singularly, less severe than any preceding attack. Finally, on the 10th of December (three weeks after the operation), there had been no return of the darting pains, and there remained but little incoördination. The patient feels the position of his legs in the bed, their sensibility is normal, and he is able to execute some complicated movements with them. He can stand upright, and walk.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following have been examined and approved for the third examination for the degree of M.B.:—

FIRST CLASS.—Mackern, Caius.

SECOND CLASS.—Benthall, B.A., Pembroke; Brunton, B.A., St. John's; R. H. Clarke, B.A., Christ's; Colman, B.A., Corpus; Coxwell, B.A., Christ's; T. Finch, B.A., Caius; H. K. Fuller, B.A., St. John's; H. R. Hutton, B.A., St. John's; Jessop, B.A., Caius; Lapage, M.A., Magdelene; J. Mason, B.A., Pembroke; Pidcock, non-collegiate; Standert, M.A., Corpus; Wedmore, B.A., St. John's.

UNIVERSITY OF DURHAM.—At a Convocation held on Dec. 14th the following degrees and licences were conferred:—

M.D. (practitioners of fifteen years).—E. Selous, W. Lattey.

M.D.—J. B. Emmerson.

M.B.—T. G. Ainsly, T. Dutton, A. W. W. Dowding, T. C. Sqaunce, G. L. Pardington.

M.S.—A. W. W. Dowding, T. C. Sqaunce.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Dec. 9th:—

Barnes, William George Kynaston, Caversham-road.

Barrow, Lancelot Andrews, Camden-road.

Campbell, Henry William, Claverton-street.

Phillips, Lawrence William Kinglake, Brighton.

Taylor, Benjamin Robert Archer, Dalston.

Thomas, Walter Duncan, Heathcote-street.

The following gentlemen also on the same day passed their Primary Professional Examination:—

William Herbert Smith, St. Thomas's Hospital; William Tibbles, Charing-cross Hospital; Geo. John Wilson, Guy's Hospital.

PRESENTATIONS.—On retiring from the office of Resident Medical Officer at the Victoria Park Hospital for Diseases of the Chest, Dr. Orlebar was presented with a handsome inkstand and writing-case and a beautifully bound Bible; while the porters and servants of the Hospital have taken the opportunity to give as their present, a very complete letter paper case for the table. When the feelings that induce sisters, nurses, porters, and servants thus to mark their appreciation of the services of one who is leaving the hospital to the great regret, but with the sincere good wishes, of the whole medical staff, it cannot but speak well for the efficient and harmonious carrying on of all the work connected with the care of the patients in the wards of the institution.—On Dec. 9th Dr. Halliday Croom was presented with an illuminated address, clock and bronzes, by upwards of one hundred of his pupils in recognition of his clinical teaching at the Royal Maternity Hospital.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

Mr. William Thomson, late of Carden-place, Aberdeen, bequeathed £100 to the Royal Infirmary, and £50 to the Children's Hospital, Aberdeen. Mr. G. Pegley, of the same town, bequeathed £25, and Mr. G. Philip, of Rayne, £5, to the Royal Infirmary. The late Mr. R. P. Jones, of Rodney Wharf, bequeathed £500 to the Newport Infirmary. The Charing-cross Hospital receives £100 under the will of the late Mr. Robert Bell, of Wimbledon. Mr. J. Marshall, late of West Hesterton Hall, bequeathed £200 to the Bradford Infirmary, and £100 to the York County Hospital. By the will of Mr. J. Deverell, late of Purbrook-park, the Winchester County Hospital becomes entitled to £100.

BABY-FARMING.—The Brighton Town Clerk prosecuted on Tuesday in a case before the borough Bench, in which Ann Ascombe, the wife of a milkman, was charged with having for hire three infants under one year old, in an unregistered house. Detective Raggett proved the case, and said he had ascertained in the past twelve months three infants under one year old had died in the defendant's house. There had been no inquests, and though the defendant had obtained certificates, she had not produced them to the coroner—an offence for which the Bench said she was liable to six months' imprisonment. The defendant, who pleaded ignorance of the law, was fined £5, with two months' hard labour in default.—*The Times*.

ROYAL ACADEMY OF ARTS.—Professor John Marshall, F.R.S., will deliver his last lecture, a special one on the Horse, this (Friday) evening at Burlington House. His demonstrations on the Bones, Joints, Muscles, Forms and Movements of Man are given on Mondays, Wednesdays, and Fridays. The last takes place on Friday the 21st proximo.

THE HUNTERIAN ORATION.—This biennial address will be delivered in the theatre of the Royal College of Surgeons on Monday, February 14th, by Mr. Luther Holden, late President of the College, on which day both the library and museum of the institution will be closed.

Notes, Short Comments, and Answers to Correspondents.

BRITISH LAWS REGULATING MEDICAL PRACTICE.

Dr. O'Leary, (Boston).—The Medical Act was passed in 1858. It created a General Medical Council, in which most of the teaching and examining bodies are represented, but in which direct representatives of the profession are conspicuous by their absence. It left nineteen bodies to give one-sided diplomas, and to compete with one another. Much effort is now being put forth to get legislation in favour of a better constituted Medical Council, and a reduction in the number of licensing bodies, by compelling existing ones to combine, and to act under stricter supervision.

THE ZOOLOGICAL SOCIETY.

THE Zoological Society has vast capabilities both as a purveyor of rational amusement and as a popular instructor, wholly apart from, and in addition to, its proper scientific work. In the discharge of its functions as an entertainer there is nothing to be desired. The gardens are admirably laid out; the collection of live animals is excellent in itself, and well kept and exhibited. Meanwhile, however, little or nothing is done to popularise the study of natural history. Certain courses of lectures are given, but they are of a class to commend themselves to the learned, or at least to the "tolerably well informed," rather than the wholly ignorant. Might it not be worth while, in a pecuniary as well as a public sense, for the Society to empower some two or three competent officials to make special tours of the garden, as the warders go round the Tower of London, at stated times daily, or whenever a sufficient number of visitors had congregated at the entrance gates, in order to point out and explain the leading specimens of animal life and their special characteristics? We shall probably be told that the experiment has at some time been made, and abandoned; but if this be the fact it has escaped our memory, and it might be useful to try it again. Even at Christmas-tide multitudes visit the gardens, and it is really desirable that the public should be informed on a subject so interesting and important as "natural history." We commend the suggestion to the Society, and we hope to see it carried into effect.

THE letter of Dr. Wynn Williams will appear in our next.

"SEAWEED AS A SUBSTITUTE FOR JAM."

To the Editor of THE LANCET.

SIR,—On the principle that any error, however small, in a scientific journal, should be corrected, I think it right to refer to a statement in last week's LANCET on the manufacture of jam from seaweed, taken from the Paris Temps. The plant used is therein stated to be *Arachnoidiscus japonicus*. Now this is a beautiful circular diatom, well known to microscopists, and which grows on several seaweeds in China and Japan; it is much prized for making soup and jelly. The varieties employed in packing are *Enteromorpha* and *Zostera*—grass wrack and sea grass; these, as most other seaweeds, furnish a sort of mucilage, but are tough and stringy. In the north they are much used as a cheap substitute for hay for stuffing mattresses and pillows.

I remain, Sir, yours obediently,

Holland-road, Kensington, Dec. 13th, 1880. GEORGE C. KAROP.

MEDICAL BOOKKEEPING.

THE forms supplied to us, and which are published by B. Allsop, of Saltaire, Yorkshire, seem to be useful and sensible. We have long been of opinion that medical men spend an undue amount of time and trouble over irksome and complicated systems of bookkeeping. The account against patients can be greatly simplified, and the forms we notice are an illustration of one of many ways, the day book combining the advantages of a day book and a visiting-list.

M.R.C.S., &c.—Before successful legal action can be taken, the pretender must assume a false title, or attend cases and supply medicines after the manner of an apothecary. For the first offence he may be prosecuted under the Medical Act; for the second, under the Apothecaries Act.

Mr. Küner's paper will be published in an early number.

BRONCHITIS COMPLICATED WITH DIARRHŒA.

To the Editor of THE LANCET.

SIR,—Upon reading over my letter in this week's LANCET, I find there is an omission of water in the prescription, which should stand thus: Ipecacuanha powder, four grains; bicarbonate of soda and bromide of sodium, of each thirty grains; syrup and gum mucilage, of each two drachms; water to two ounces: two teaspoonfuls to be given every three or four hours, &c.

Earl's-court-road, W., Dec. 14th, 1880.

Yours truly,
E. MAY, M.R.C.P.

THE "MEDICAL ANNUAL FOR 1889, OR BRITISH MEDICAL ALMANACK."

A CORRESPONDENT desires an opportunity of referring to a copy of the above work, edited by Dr. William Farr, F.R.S., and reviewed in THE LANCET, December 1st, 1888. The "Annual" contains a history of the Medical Profession, and its influence on the Public Health.

Dr. J. J. Mackenzie.—The general rule at hospitals is to refuse admission to self-discharged patients, unless there are imperative reasons to the contrary—e.g., the patient may be too ill to have seen the folly of his conduct, and to readmit him would be acting in the spirit of charity, which should always govern the management of the institution. But readmissions should be under the same medical officer as far as possible.

L.R.C.P. should clearly decline to practise in the town if he is not prepared to purchase.

Dr. John Moore, (Belfast).—The resolutions have not come to hand.

A SANITARY INCIDENT OF THE WOOD-PAVING PROCESS.

Whether the globules of diluted carbolie acid shot into the atmosphere of an operating theatre, with the mitrailleuse-like spray apparatus, really hit and kill the minute "germs" supposed to be floating around, the dissemination of petroleum and tar in the general air of a thoroughfare in process of paving with wood by any of the several methods in use, can scarcely fail to be healthful. The atmosphere is pervaded with the vapour, and it finds its way into the air-passages of the passing multitude, while it impregnates their clothes and overpowers less innocent odours, if it does not neutralise the floating infection of disease. Anyone may be fumigated gratuitously at the cost of a few moments' lingering over the reeking vats to be found in most of our principal streets. Nor is the opportunity an exceptional boon. What with asphalt-paving and wood-paving, more particularly the latter, there are few populous neighbourhoods where an open-air fumigation may not be obtained. The perpetual repairing these pavements seem to require, gives promise of a perennial enjoyment of the luxury. The incident of these processes to which we have alluded has doubtless a sanitary aspect, which should be recognised. In the old days they burnt tar-barrels for health purposes; in these we pave our streets with a liquid disinfectant. Thus do modern improvements lead to public health.

Dr. Lewins is thanked for his interesting communication; but the subject, being of so purely speculative a nature, is one to which we cannot afford further space.

Great Driffield.—Our correspondent does not seem to have observed that the candidate possesses the necessary legal qualifications.

H. J. F. has forgotten to enclose his card.

"A NOTE ON INTENTION IN THE DETERMINATION OF SEX AND OF THE MENTAL AND PHYSICAL INHERITANCE OF CHILDREN."

To the Editor of THE LANCET.

SIR,—If I were less "confident" than I am of the substantial accuracy of the "statements" I have submitted in relation with this subject, I should have been glad to have elicited from Mr. Charles Roberts the excellent summary of the orthodox theory of sex-determination which appeared in your last issue. He has done ample justice to the topic within the limits of the view he takes. The only mistake he makes is in supposing his idea to be original. It is simply the accepted explanation of the phenomena, and the class of statistics from which Mr. Roberts draws his data are duly accredited and interpreted precisely as he states, and employs, them. The chief novelty in his argument is the extent to which he pushes the construction commonly placed on the figures he cites, and the emphasis he throws on the part played by the female. I will not attempt to follow his reasoning, but content myself by formulating a few further results of the investigation I have made, leaving Mr. Roberts, and others interested in the subject, to see how they bear on the received theories of sex-determination and heredity, and how far they support my own alternative conclusions. Obviously I can make no claim to originality for the conclusions at which I have arrived, because they are the necessary inferences derived from facts over which I and other observers have had no control. Time will show whether my interpretation of the facts is justified, and to time I will now leave the judgment.

1. Sex is the result of an arrest or repression of the force of development in the case of the female. The male of every family in the animal kingdom is the best and fullest specimen of development, having regard to the purposes and habits of life of the species, class, or family. In those apparent exceptions where the male is the smaller and less displayed animal, that is because it is an advantage in regard to the life and habits of the class to be small and unobtrusive.

2. The arrest in point of development which characterises the female has nothing in common with immaturity, and is therefore not a conclusive proof of inferiority. It is, as it were, a repression of the formative force, and the physical result of this repression is a perpetual effort to develop or reproduce. The force arrested in the individual gathers intensity, so to say, and expresses itself in a perpetual and characteristic longing to produce a perfect animal. The perfection denied or inhibited in the individual is sought in the progeny. Hence the natural tendency of the female to produce male children, and, as a necessary result, the majority of children born are males. It is not a question of the comparative amount of ardency in the two sexes, but of the direction of the force or intention—I do not now mean conscious intention, but the intention or purposiveness of Nature—in the case of the female. This direction will always be followed in sex-determination unless that force is neutralised by the male.

3. The function of the male is not one of production, but of fecundation. The tendency of what I have called *ardency* in the performance of this function is to neutralise or control the productive force of the female, and, thus, determine that *arrest* of development which results in female offspring. Here, again, there is no question of the comparative amount of ardency in the two sexes, because the ardency of the male may be so dissipated by the extent of its activity as to be in no instance domi-

nant; or it may be restrained and intensified, and, therefore, when it acts assert supremacy.

4. The way constitutional strength comes into play, as it undoubtedly does, in sex-determination, is by giving vigour to the natural action of the laws I have tried to lay down, not by so changing the operation of those laws as to make them non-natural.

The passage from the Talmud quoted by "W. O. J." is so far interesting, as it shows that the facts to which I have alluded have been long recognised; but the hypothesis I have assumed is not in any way illustrated by the passage itself, which is obviously founded on a misconception of the facts; and a confounding of the impulse I have designated "ardency" with animal passion. In my theory the two are wholly distinct, and have nothing in common, except as the power of self-control may be an indication of nervous force.

I am obliged to "A. G. P." for his reference; but I lay no stress on the question of the placenta or placentae, and only alluded to it incidentally. It does not affect my conclusions. This correspondent seems to attach greater importance to the accident of twin-births than I can admit. Twin-birth does not imply twin-conception.

The hereditary tendency to produce twins, to which Mr. G. Hodgson alludes, exactly accords with the remarks I have offered above. Twins are generally female, and argue an excess, or dispersion, of the force of development on the part of the mother. "A. G. P." will find ample proof that the rules on which I have founded my remarks do obtain in the development of stock. I have not studied the operation of the law among birds or small domestic animals.

In answer to Mr. William Story, I would suggest that an antagonism of equal forces might produce a neutral result; but the laws governing the development of monsters are obviously laws of development rather than of procreation, and they come into play after conception. The hereditary proclivity to the production of families of one sex generally lies in the female line, and exactly accords with the principles I have stated. As to general heredity, it must often happen that what I have called the underlying elements or forces descending or operating in the direct line are so strong as to resist the influence of the elements or forces descending or operating in the oblique. If this were not so, there could be no such phenomenon as family likeness following the family name, as I was careful to point out. The theory of reproduction propounded by Mr. Roberts is, of course, at variance with the experience of breeders in respect to the value of the sire.

I will only remark in conclusion, that the data on which my speculations are founded, and from which my inferences are drawn, are too numerous to adduce in your columns. Nor would it be worth while to adduce them. I have simply desired to throw out a suggestion for the consideration of observers, and I am well satisfied with the manner in which it has been received.

Yours obediently,

Welbeck-street, Dec. 1880.

JOSEPH MORTIMER GRANVILLE.

P.S.—In the title of my paper, and generally throughout the remarks I have offered, the word "intention" has been employed to signify human will and purpose; but in the passage above (marked) I have used it to indicate the purpose, or intention, of Nature—that is, the inner working of natural laws which it may, and as I think should, be the aim of the human will to call into operation by a careful and intentional arrangement of conditions and circumstances. With this explanation the discussion, so far as I am concerned, may now close.

J. M. G.

H. P.—We cannot believe that our correspondent really expects us to take up the question of what he considers an injustice inflicted by a Royal Warrant twenty-one years ago. At the time of its promulgation the department was perfectly satisfied with it, and believed it to have been framed in a liberal and enlightened spirit. It would be useless to enter upon a discussion of the subject with our correspondent. We shall merely remark that what he calls "identically similar circumstances" are, in our opinion, very different from those with which he makes the comparison.

A Victim will find such cases referred to in THE LANCET of Jan. 24th and Feb. 7th, 1880.

Dr. Irvine's letter will appear probably in our next.

PICTURES FROM IRELAND: A DISPENSARY DOCTOR

To the Editor of THE LANCET.

SIR,—Have you seen a work by Terence Magrath, called "Picture from Ireland"? A chapter in it, called "A Dispensary Doctor," is certainly worth reading. I see the book lying about the Club-tables. Taken in connexion with Tennyson's lines, "In a Child's Hospital," it does not give a flattering character to medical men. See also Ali Baba's "One Day in India" from *Vanity Fair*—viz., "The Civil Surgeon." Can all these pictures be true?

Dec. 1880.

Yours &c.,

C. R. V.

F. E. M.—The word "overseer" will also include an assistant-overseer, having the duties of an overseer delegated to him in his warrant of appointment under the 59th George III., c. 12, s. 7 (Glen's Poor-law Orders).

Old Subscriber.—It is a mistake to give the certificates without first settling the question of fees.

Dr. Lownds, (Egham).—It is a question entirely of choice and knowledge of the individual.

A Subscriber is referred to our article on Books in the Students' Number, Sept. 11th.

MEDICAL FEES.

J. A. W.—Our view of all such questions is that the practitioner is by far the most competent judge, as he is best aware of the time and trouble he has spent over cases, the means of patients, the general fees of the district, &c. But we have no hesitation in saying that in this case we think the charge of a guinea per visit was very reasonable indeed. Parents or patients are quite entitled to have a consultee at every visit of the medical man if they please; but this does not in any way diminish the right of the general practitioner to be paid for his services and his share in long consultations.

"NUTRICINE."

To the Editor of THE LANCET.

SIR,—Allow me to state in reference to the paragraph which, under the above heading, appeared in your issue of the 4th inst., that I am the inventor of the new chemical food described by M. Moride in the paper read before the French Academy of Sciences on the 8th ultimo, and which he calls nutritine.

The *Official Patents Journal* of July 2nd announced my application for provisional protection for a process for treating meat with farina and other ingredients. The proportions of farina to meat that I employ vary considerably, according to the object in view. That which I have found the most useful corresponds exactly with the water to be displaced. Thus, taking raw juicy beef, cut fresh from the carcase, free from bone, tendons, and fat, to contain 75 per cent. of water, I employ twelve ounces of whole wheat, or oatmeal, to each sixteen ounces of beef. The product after treatment is, within a few grains more or less, sixteen ounces. This product presents chemically and physiologically, minus water, one pound of fresh beef and 12 ounces of flour, or 14 ounces of bread. The patent was sealed in due course.

Further to prove the priority of my invention, if it be necessary, I may state that samples of nutritine were submitted to Mr. Jabez Hogg for microscopic examination, and subsequently by him to Mr. F. Woodland Toms, F.C.S., for chemical analysis, as far back as last May.

The value of this new organic compound—which contains within itself all the elements of a normal diet (perfect food), and its various applications in medicine,—I will not now stop to discuss, merely mentioning that I intend to make it the basis of various foods for hospital use, each having a definite physiological value. I believe it will not be the least interesting feature of this new compound of animal and vegetable substances, that it will supply the physician with a means of treating diet practically on scientific principles.

I remain, your obedient servant,

Beckenham, Dec. 15th, 1880.

E. A. KIRBY, M.D.

E. F. P.—Tasmania and New Zealand would probably be most suitable. If the patient is a good sailor, he should go round the Cape of Good Hope. He should follow an open air occupation.

ERRATUM.—One important and two minor errors crept into a short review of Mr. Ball's Elements of Astronomy, contained in last week's LANCET. The important error is that the work is published by "Messrs. Longman," and not, as stated, by "Messrs. Macmillan." The minor errors are that "Jenkins" should be "Jenkin," and the Physiological Botany, published by "Thorne," should be by "Thomé."

SUBSTANCE OF A

Clinical Lecture

ON

CASES OF ACUTE ATROPHIC PARALYSIS IN
INFANTS AND ADULTS

(ACUTE ANTERIOR POLIO-MYELITIS).

*Delivered at the National Hospital for the Paralysed
and Epileptic, on Dec. 9th, 1880,*

By THOMAS BUZZARD, M.D., F.R.C.P.

LECTURE II.

GENTLEMEN,—Some thirty years ago Marshall Hall applied the term *cerebral paralysis* to that condition in which a lesion cuts off the cerebral influence, and *spinal paralysis* to that in which a lesion cuts off the spinal influence from the paralysed limbs. The first patient before you (a case of ordinary left hemiplegia) is an example of cerebral paralysis. He has but very small power of moving his left arm. His deltoid muscle, which is plump, responds readily, however, as you see, to induced currents of moderate strength. The other man (a case of acute anterior polio-myelitis affecting both arms, whom Dr. Jackson and Dr. Ferrier have kindly permitted me to show you) is an example of spinal paralysis. His deltoid muscle is wasted, and refuses to react to the strongest induced currents. When, however, I apply to it a current from twenty cells of Coxeter's battery, and slowly interrupt this, there is vivid contraction of the muscle. This, the "reaction of degeneration" is shown also by a certain qualitative change which I can demonstrate to you. In health the sudden closure of a voltaic circuit of moderate strength, whilst the kathode (or negative pole) is on a muscle, causes a slight contraction, which is represented, according to Brenner's formula, as KSZ (Kathode, Schliessung=shutting; Zuckung=contraction). When the current is increased a stronger contraction occurs, KSZ (represented by a large Z), and in addition a slight contraction now also takes place when the circuit is either opened or shut with the anode, or positive pole, on the muscle, AOZ, ASZ (Oeffnung=opening). But in this patient, as you see, the contraction when the circuit is made with the anode on the muscle is considerably stronger than that with the kathode. So we record the electrical reaction in this man's deltoid as $\text{Far.}=0$, Galvan. $\text{ASZ} > \text{KSZ}$.¹

This is a characteristic example of a qualitative change in the reaction of degeneration.

The *diagnosis* of this disease is not usually difficult. A febrile attack followed by rapid loss of power in one or more limbs points almost conclusively in children to acute anterior polio-myelitis if you find in the course of a week that many of the muscles paralysed exhibit lost or greatly reduced faradaic excitability. There is just the chance, however, that you may be concerned with a traumatic or other lesion of a single nerve-trunk. The child may have been exposed to cold, and a nerve of the lower or upper extremity may be affected, as the portio dura so often is from this cause. In such a case there would be paralysis, wasting, and loss of faradaic excitability exactly confined within the district of a certain nerve. But in anterior polio-myelitis muscles in the districts of different nerves are liable to be affected; and, again, all the muscles in a particular nerve-district are not equally affected. The possibility of pachymeningitis must also be excluded. This is more gradual in its progress, and will be attended by severe pains and cutaneous anæsthesia. Otherwise the symptoms resemble,

for there is paralysis, wasting, and reaction of degeneration. It is still more difficult to exclude disease of the anterior roots alone, which, however, is rare. The attendant circumstances will probably aid the diagnosis.

I saw some time ago a child, one year old, who was said to have lost the use of the right lower limb the day before, after a little malaise and fever. When stripped it was evident that the limb was powerless, and it was also tender, for the child protected it from being touched. The aspect was much that of infantile paralysis. There was no fracture. But its urine abounded in uric acid, and it seemed the child had been fed for a long while on a milk food which contained an enormous quantity of sugar. I thought it likely there might be some inflammation of the loose connective tissue between the muscles of the thigh, caused by the deposit in it of uric acid. (These collections of tissue, according to recent investigations, are really extensions of the lymphatic system.) A few doses of citrate of potash cured the child in a day or two. Such a cause is probably at the bottom of those cases of sciatica and lumbago which are rapidly cured by purging and alkalies. I owe to Dr. Burdon-Sanderson the idea that deposits in these extensions of the lymphatic system might lead to symptoms of this kind.

Arthur D—, aged eighteen, came here on account of nervous symptoms, from which he has recovered; but, as you see, he exhibits the results of a paralytic attack, which he describes as having occurred in infancy. There is want of power in the *left leg, right arm*, and, what is especially notable, the *right side of the face*. Now, if this were a case of alternate hemiplegia (from disease of the lower part of the pons Varolii), the left arm (not the right) ought to have been paralysed. Moreover, any wasting in the left lower limb as a result of disuse would have been proportionate above and below the knee. But you will observe that whilst the left thigh is three inches, the left calf is only a quarter of an inch less than its fellow. Moreover, the wasting involves the district of the anterior crural nerve and only a part of that of the sciatic. The patellar tendon-reflex is absent on the left side. The case is evidently one of acute polio-myelitis, involving not only the spinal centres for the left leg and right arm, but also the nucleus of the portio dura (for the right side) in the medulla oblongata, which, with certain other nuclei, is continuous upwards and homologous with the ganglion-cells in the anterior horns of the cord. It is, I think, extremely rare to find the complication of facial paralysis in this disease. May not this be because if the affection invades the medulla oblongata at all, it is liable to attack centres essential to life? I would suggest the possibility that some cases of rapid death in previously healthy persons (for which no explanation is found) may be due to acute polio-myelitis attacking the cardiac and respiratory centres.

B—, aged twenty (patient of Dr. Ormerod), came here for fits, but incidentally mentioned having been paralysed in the left leg in infancy. The other limbs, he said, had nothing wrong. You will see, however, now that he is stripped, that the right leg is really not much more developed than the left, and the patellar tendon-reflex is absent on that side as well as the other. A short time since I saw a young man who had been paralysed in the left leg from infancy, all four limbs having, according to his account, been at first affected, but the others having quite recovered. Examination showed the tendon-reflex absent in both legs, and the faradaic excitability (which was quite lost in the left leg) greatly reduced in the supposed sound limb. Helena M—, a child now attending, who was brought here on account of paralysis, supposed by her mother to affect the right leg exclusively, has no patellar tendon-reflex in *either* leg, and certain muscles in the left leg will not react to either current. I am disposed to think that monoplegia in this disease is far less common than is usually stated, and that, as in these cases, limbs are very frequently supposed to be sound which are, in reality, only comparatively so.

As regards *etiology*, the influence of cold and of injury to the back, as causes, is supported by evidence. Alcohol is probably not a cause. The disease occurs most frequently in those (infants and children) who have never taken any. Let me note also a curious fact as regards some adult cases. George B—, aged twenty-one, has totally abstained for eight years. Mary F—, aged sixteen, has taken little or none in her life. A young lady whom I saw lately in consultation, and of whom I asked the question, had taken no alcohol for five years.

The *prognosis* is very important. Duchenne's observations,

C C

¹ Let me appeal to English-speaking neurologists to adopt the German notation for these qualitative changes. If we use the word "shutting" instead of "closing" as regards the circuit, and accept the letter Z as an arbitrary sign implying contraction (and there is something in the form of the letter suggestive of it), records made by English and German will be mutually intelligible without the necessity of that kind of wearisome translation of which we have already quite enough in respect to thermometrical and mensural notation. The Germans have set us the example by employing the terms anode and kathode devised by Faraday.

and F. Müller's more recently, tend to show that all muscles in which faradaic excitability has disappeared entirely in the first four or five days are permanently paralysed. In all those in which some faradaic excitability is retained after from the eighth to the twelfth day, motility may be expected to return even though several months may be required. You cannot judge of the future from the existence of reaction of degeneration in the first stage, nor even, as it seems to me, from the disappearance of reaction to both currents. In the patient Mary F—, aged sixteen, who was attacked with polio-myelitis affecting both lower extremities nearly a year ago, four months after the attack the right quadriceps extensor showed no reaction to *either current*; it now reacts freely to twenty cells. In another, Geo. B—, aged twenty-one, whom I present to you, you have the opportunity of comparing his present condition with a note taken by Mr. Broster eleven days after his attack of polio-myelitis twenty-six months ago, when he came into the hospital. There was then no reaction to faradaism in any muscle of both *lower extremities*, except the left vastus internus. Those of the *left arm* acted to somewhat strong currents. The muscles of the lower limbs acted to slow interruptions of fifteen cells constant current. At that time, in the *left lower extremity* the only movements practicable were flexion of the thigh on the trunk and rotation of it inwards and outwards; in the *right limb* a very slight flexion of the toes. The left arm was weak and wasted. The patellar tendon-reflex, as well as the skin-reflex from the soles, was absent on each side. Three months later the *right lower limb* still remained motionless and wasted. He could now draw up the left leg and lift the left foot off the bed. The left arm had recovered. A month more and the wasting process had ceased; the thighs and legs had recovered two inches of girth, which they have never since lost. At this time the left quadriceps extensor reacted to faradaism. Thirteen months after the attack he could flex the *right leg* a little on the thigh, but could not extend it; could adduct but not abduct it. The patellar tendon-reflex had returned in the left leg, not in the right. More than a twelvemonth has passed since that observation was made. It is very interesting to see that he has still further, though but slightly, improved. He can now extend the right leg a little and flex it readily. There is no reaction to faradaism, however, in the quadriceps of the right side, and the contraction to a strong constant current is slight. In the left quadriceps there is still reaction of degeneration and ASZ>KSZ.

Were I called upon to treat a case of this disease from the first I should keep the patient in bed for many months. During the first few hours, if possible, ergot should be given frequently in large doses, but not continued after a week. The muscles should be tested electrically in the course of the second week, for purposes of prognosis. A mild constant current (stable) might be used for five minutes to the spinal cord three times a week, taking care not to give shocks. Any energetic electrical treatment should, however, be avoided. When any tendency to contraction and consequent deformity showed itself, I would let the patient wear in bed some light apparatus to compensate for the paralysed muscles, and I would particularly discourage strenuous attempts at voluntary movement of paralysed muscles, as tending to excite action in their antagonists, and thereby increase the deformity.

REMARKS ON THE PERITONEAL TUBERCULOSIS OF CHILDREN.

By GEORGE GARLICK, M.D. LOND.,

LATE REGISTRAR, HOSPITAL FOR CHILDREN, GREAT ORMOND-STREET.

THE disease which has as its essential lesion a deposit of tubercles in the peritoneum simulates in its different forms some other diseases. Thus at one time it may be quite latent throughout its course, at another produce a subacute peritonitis; now showing ascites as its most prominent symptom, and again feigning in its large tumours and nodules a case of malignant disease. Various classifications of it have been offered by different authors. Thus, Drs. Wilks and Moxon in their *Pathological Anatomy* describe three forms—1. Tubercular ascites, 2. Latent peritoneal tubercle,

3. Cases of inextricable union of the bowels and viscera to one another, and to the abdominal parietes. Dr. Bristowe, in "*Reynolds's System of Medicine*," separating those cases which present obvious indications of abdominal disease, gives two classes—1st. Acute, often resembling enteric. 2nd. Chronic, in which at some period ascites is usually present. In "*Ziemssen's Cyclopædia of Practical Medicine*," following Kanlich, three groups are distinguished—1st. Acute onset; fitful course; absence of effusion; diffused adhesions and points of resistance. 2nd. Latent onset; ascites the most prominent symptom, and causing others; tumours in the abdomen. 3rd. Like Class 2, but with temporary subsidence of symptoms. Dr. West, in his "*Diseases of Infancy and Childhood*," classifies according to their symptoms and rapidity of course. Other divisions of the subject have been made by the numerous writers, but they need not be here mentioned. The chief value of these classifications appears to be that they characterise and help to keep in mind the various forms of the malady; they do not aim at an exact scientific basis of division, partly on account of the difficulty that arises in diagnosing the frequently complex conditions, but also because of the doubtful position of cases which present large deposits of caseous material in the peritoneum, the point at issue being whether these ought to be considered as simple, or as tubercular peritonitis.

So as the subject labours under this difficulty the mode of division must be mainly clinical, and we may distinguish the following classes:—

1st. Latent cases of tubercle in the peritoneum—(a) part of a general tuberculosis, (b) secondary to tubercular ulcers but purely local.

2nd. Cases characterised by an ascites, which may mask all other conditions.

3rd. Those in which obvious, and often very large, tumours are found, and in a belly not otherwise markedly resistant.

4th. In which all the abdominal contents and abdominal wall are mutually and inextricably united, often with attendant intercommunication of different parts.

5th. Mixed cases, showing diffused adhesions and points of resistance, and running a variable course.

It might be thought that Classes 2 and 3 should be combined, as, indeed, they are in most classifications. They are separated here because a large collection of fluid will prevent the palpation of tumours, and also because some cases showing abdominal indurations have had no effusion throughout their course. The classes have been made strongly contrasting for the avowed object of showing the different aspects of the disease.

1st. The latent form is probably the most frequent, but has nothing to do with the cause of death. Its latency results either from the absence of inflammatory change, or from the obscuring of its symptoms by the more grave affections of other organs. The chief interest attaches to the question of the existence of tubercular ulceration. Pus can be demonstrated in the stools even when the area of ulceration is small, and occasionally the stool may be almost entirely composed of pus; but simple ulceration may yield stools quite identical in character with the preceding. The general aspect of a case of tubercular ulceration was found in another case, post-mortem, to have resulted from albuminoid degeneration of the villi of the small intestine, there being no such change in the liver and kidney. In this case the question arose, whether an ordinary catarrhal diarrhoea might not thus perpetuate itself. I am not aware that this possible cause of an intractable diarrhoea has been worked out.

2nd. Although most authorities state that some effusion of fluid is found during the course of most cases of tubercular peritonitis, this is said to be small in amount, the fact not being usually enunciated clearly that the amount may be so considerable as to produce symptoms of its own—as oedema of the feet and abdominal walls, enlargement of the veins of the abdominal wall, &c. This fact is mentioned by Murchison, who suggests that in these cases there may be a deposit in the portal lymphatics pressing on the portal veins. Be this as it may, a complete and rapid absorption frequently takes place, and it is quite remarkable to see how the child will pick up in health and strength. A little girl, aged six years and a half, who presented marked symptoms of ascites, with a tense and oedematous abdominal wall, had the abdomen reduced whilst under observation $4\frac{1}{2}$ inches in circumference—that is, from 29 to $24\frac{1}{2}$ inches, all signs of fluid

disappearing; and, as is frequently the case, an indurated band then became palpable; the child was then transferred to the country, and returned looking well, but with the band still existing. Sometimes the fluid thrown out is pus, and an abundant discharge occurs from the navel, this continuing for months.

3rd. Tumours are found—that is, well-defined masses, not mere local sensations of resistance. Their situation and shape varies greatly. What is most characteristic is a hard, transverse, ruler-like band, situated about or above the navel, sometimes stretching right across the abdomen, losing its definition at its extremities, or passing into other masses. I have measured one of these, more than eight inches in length. The abdomen in which they are found looks large, and with frequently well-nourished walls, yielding little or no resistance on pressure; and the readiness with which the hand rolls over the band, gives no idea to the touch of an obliterated peritoneal cavity, with closely adherent viscera, such as is found in the following class of cases. A tumour of this kind is usually due to a thickened and rolled-up great omentum; to produce this the process must be chronic and localised, else adhesions form and keep the membrane extended out when either a general resistance is felt or an irregular tumour in front of the abdomen. In the acuter cases, in which there is frequently an opportunity of making a post-mortem, the great omentum may be half an inch thick, with a mass having the granular aspect of aggregated tubercle. In one chronic case I have seen masses like congealed fat or suet and quite structureless, and situated in the omentum, mesentery, and retro-peritoneal tissue; whether these latter cases are to be considered as tubercular it is at present difficult to decide. In a case reported by Dr. Hilton Fagge, in which tubercular peritonitis was mistaken for ovarian disease and operated upon, the peritoneum was found strewn with tubercles and the intestines matted together, still recovery occurred, and six years later the patient was seen fat and well; this shows a power of recovery from extensive tubercular deposit which should make one slow in arguing against their tubercular origin from the mere recoverability of the case. A mass is found frequently in the right iliac fossa, due to thickening of the cæcal wall combined with some enlarged glands here, and general thickening and adhesions of the surrounding peritoneal covering; this is not an uncommon lesion, and results from the fact that a chronic and sub-localised tubercular ulceration is frequently found about the cæcum, and leads to few symptoms but wasting and fever. Enlarged mesenteric glands have been mentioned here as forming part of the tumour, and in fact they often cannot be diagnosed from other masses, but they are not very often felt and still less often demonstrated post-mortem after being felt; but this is due largely to the fact that these cases often recover. It is curious to see the disproportion often existing between the amount of tubercular disease of the bowel, &c., and the enlargement of the mesenteric glands; thus the peritoneum may be strewn with tubercle, and there may be deep ulceration of the cæcum and of Peyer's patches above, with only moderate enlargement of the mesenteric glands; the great enlargement also which occurs in some cases without any such origin contrasts strongly with the preceding. These cases have also to be diagnosed from cancer of the peritoneum and faecal accumulation.

The following case may be given as an example of this class:—

Alice C—, aged three years and a half, admitted on April 26th, 1878, into the Hospital for Sick Children, under the care of Dr. Gee. The mother's account was that another of her children had died of consumptive bowels. Alice was subject occasionally to attacks of vomiting and diarrhoea, and for the last three weeks the diarrhoea had been much worse, slime and blood being passed with much abdominal pain; at the same time the appetite was good, and there was no great loss of flesh. The bowel often prolapsed. On admission the child was pale, anæmic, and flabby, but with a fair amount of flesh. The stomach was remarkably large and inflated, but could be readily palpated, yielding no resistance anywhere, and had yielded at the navel, forming a small rupture. Liver about two inches below the ribs on right nipple line; spleen not palpable; the tongue was moist and clean, but pale. The bowels were moved frequently, the motions being offensive, pultaceous, and composed largely of curds with a little slime. Dr. Gee examined them microscopically, and found partially digested muscular fibres, with a few doubtful cells, probably mucous corpuscles. She

was dieted on Swiss milk, raw meat, biscuits and toast, and for medicine took one drachm of compound decoction of aloes three times daily. For three months treatment varied from time to time, was kept up most assiduously, but with little decided result, except that some days the motions were more solid and improved in colour, and the child's general condition was rather better. During this time the spleen enlarged, and towards the end a crop of boils appeared on the head, the child for the first time becoming febrile. Rather more than three months from admission a band appeared, transversely placed, a little above the navel. The child was then sent to Highgate, as it did not improve, the band remaining quite distinct. Part of the treatment employed may be mentioned here, owing to the marked success that it has in cases of chronic diarrhoea in which all else has failed; it was the constant wearing next the abdomen of a large piece of spongio-piline, moistened twice daily with a mixture of two drachms of tincture of iodine and eight ounces of camphor water; it is a most valuable agent.

4. Universal firm adhesions. This, when combined with perforations of the gut and intercommunication, converts the abdomen into a trabeculated cavity. It is amongst these cases we find the character of abdomen so often described—the pigmented, scaling, thin-walled belly, with its wasted, tendinous-feeling muscles, its hard subcutaneous points, and a feeling of tense resistance, due to the immobility of its contents, &c. This fixation of the contents may be felt also in the almost stationary lower edge of the liver during inspiration; this sign often fails from the elevation of that organ above the margin of the ribs. The elevation of the heart at the same time, combined with a retraction of the lung, may so elevate the cardiac dullness as to suggest the existence of enlarged mediastinal glands. Here, too, we have often the most marked symptoms, the extreme degrees of emaciation, with diarrhoea and attacks of severe abdominal pains, leading to a speedy death. The following is a good example of a case of this class:—

Henry G—, aged nine years, admitted Dec. 9th, 1876, under Dr. Dickinson, into the Hospital for Sick Children, Great Ormond-street. There was phthisis in the families of both parents, and two other children had died of tubercular disease. This child had been ill nine weeks with abdominal pain and diarrhoea (the motions pale, and fermenting like yeast), occasional vomiting, cramps in the legs and feet, wasting, and night-sweats. He was a pallid boy, with long, light hair, markedly wasted, and with an anxious, drawn face. The abdomen, in contrast with the rest of the body, was tumid and tense, with distinct veins in the walls, and its rounded contour obliterated all the markings of health; a general want of resonance and resistance, but with no palpable tumours. The tongue clean, but red and irritable. About twice daily he passed a very large, diffuent, ash-grey, offensive motion. The chest showed consolidation of the left apex, and the heart was raised and uncovered, beating in the second and fourth spaces. The child only lived five weeks after this, having feverish attacks, frequently crying out with abdominal pain, progressively wasting, and having a cadaverous smell. After death extensive lung mischief was found. The abdominal contents were so glued together that the intestine could only be cut out in pieces, and at various parts apertures united contiguous parts of the bowel. The liver was firmly fixed all round, and highly fatty.

Great James-street, W.C.

THE ORIGIN OF CROSS-LEGGED PROGRESSION (SCISSOR-LEGGED DEFORMITY), ASSOCIATED WITH DOUBLE HIP-ANCHYLOSIS.

By R. CLEMENT LUCAS, B.S. LOND., F.R.C.S.,
SENIOR ASSISTANT-SURGEON TO, AND DEMONSTRATOR OF OPERATIVE
AND PRACTICAL SURGERY AT, GUY'S HOSPITAL.

IN the paper which I read before the Clinical Society on October 22nd, directing attention to this peculiar deformity and odd method of progression, I stated that I particularly wished to hear discussed the theory of its origin, and to learn from others their views of its cause. The speakers in the discussion which followed did not agree as to the probable cause, and each theory put forward had much sound

reasoning to support it. I therefore desire to state concisely what those theories were, with the object of gaining further information on the origin of the deformity.

For such as may not have noticed the paper it may be well to state that the deformity is associated with, and maintained by, ankylosis of both hip-joints, in a position of extreme adduction and eversion. The legs cross opposite the knees, the heels are wide apart, whilst the toes are approximated, and the patients walk from the knees instead of from the hips.

The first theory, which may be called the simple *adduction* theory, received, if I understood aright, the support of Mr. Howard Marsh. It would attribute the deformity to the action of the adductor muscles having been unopposed during the process of repair. Adduction, as is well known, is very common in hip-joint disease, but it is usually associated with flexion and inversion. Adduction with extension and extreme eversion must be very rare, and for this reason the theory of unopposed muscular contraction did not appear to me to be altogether satisfactory.

Instances of flexion and adduction, with inversion, are occasionally met with in patients long bedridden, who have no hip-joint disease. They belong to an entirely different class to that which I have described, but may be used in support of the theory of simple muscular contraction. An extreme case of this kind is figured in Dr. Little's work on deformities. In this case there was semi-flexion and adduction, causing the thighs to cross above the knees, and, as can be seen by the engraving, inversion of the legs. The author relates the case as follows: "Another remarkable contracture from preponderance of one set of muscles and habitual retention in one position, is afforded by the subject of Fig. 74, which represents the case of a lady, aged fifteen, who seven years before laboured under severe typhus fever, during which extensive sloughs posteriorly, involving very nearly the whole of the sacrum and nates, and laterally exposing both trochanters, occurred. Probably through weakening of the glutei muscles, the adductors of the thigh habitually drew the limbs inwardly, and ultimately their contraction being unresisted by volition, crossed the limbs over each other, in which uncommon position they were rigidly fixed at the time of the author's first examination." In a note it is said "she had not walked since the original illness." In my cases there was extension with extreme adduction and eversion, and it is the accompaniment of extreme eversion with adduction which leads me to think that some volition or design determined, in part at least, the peculiar deformity I have described.

The second theory, which may be called the *gravitation* theory, was very ingeniously demonstrated by Mr. Croft. It was suggested that the first hip became ankylosed in an adducted position, and then, when afterwards the patient walked with the aid of crutches, the other limb fell naturally across the one fixed, in order that the line of gravity might be between them. Against this view it may be urged that a patient walking on crutches and one leg, in consequence of disease of the opposite hip, does not, as a rule, carry the lame leg in front or behind the other, but retains it in a semi-flexed position on its proper side. On the other hand, since writing my paper, I have seen a man walking with crutches and slightly crossed-legged, who had no hip disease. He had suffered during two or three years from partial paralysis of the right side. In this case the paralysed leg fell behind the sound one, and it might be argued that it was so placed by the action of gravity. It was in the man's power to abduct, flex, or place the lame leg in any position he pleased, but he found it most convenient for progression to carry it behind and a little to the outside of the other. When walking he received the weight of his body from the crutches first upon the weak limb, then quickly transferred it to the sound one before carrying forward his crutches to take the next step. This case, if used in support of the gravitation theory, would do away with the supposed necessity for the limb first attacked to be ankylosed in an adducted position, since any adduction of the sound limb in this case must have been voluntary.

The explanation of the course of events antecedent to ankylosis which I put forward as probable—not dogmatically, but rather to elicit comments—need not be regarded as opposed to either of the other views, but may be made to include both. It would leave to the patient a certain *natural selection* or *option*, which induces him to choose by preference a position that gives most rest to the inflamed hip, and afterwards leads him to maintain or even increase the

deformity, because the position is one which allows most easy progression when both hips are ankylosed. Supposing one hip to have recovered sufficiently to bear the weight of the body, and the other hip to be in a state of acute inflammation, the patient will try to bear all his weight on the convalescent limb and endeavour to fix and rest the other. With crutches he is enabled to effect this. The limb last attacked, when carried across the other so that the patella of the latter fits into the popliteal space, is supported, fixed, and prevented from touching the ground. With lessening pain in the inflamed hip the patient becomes anxious to test its powers. He is conscious that any attempt to move the hip will cause him pain, and he accordingly tests its weight-bearing powers by dropping the foot to the ground on the spot over which it has been hanging. When assured of its power to sustain the weight of the body, he attempts to walk, and finds that the more the limbs are everted the more extensive is the movement emanating from the knees. Hence, first, for the purpose of relieving pain, and afterwards for convenience in walking, he habitually retains his limbs in a position which ankylosis eventually seals. I thought it an argument in support of this view that in both my cases the limb last attacked was the one carried in front, whereas in the case of the man suffering from partial paralysis, the weakened limb was carried behind the other; but since then Mr. Tyson has shown a man at the Clinical Society in whose case the limb last attacked was behind the other. Mr. Croft, in the discussion on my paper, pointed out that in the boy pathological dislocation had taken place in both hips without suppurative. Mr. Heath's inquiry as to the condition of the hips in the man led to the appointment of a committee, which has reported that in his case the hips are not dislocated. Thus dislocation is proved not to be the determining cause of the scissors-like deformity.

Finsbury-square.

FURTHER OBSERVATIONS ON STERTOR; ITS PATHOLOGY AND TREATMENT.

By ROBERT L. BOWLES, M.D.

(Communicated by CÆSAR HAWKINS, F.R.S.)

(Concluded from p. 373.)

THE consideration last mentioned induced me to adopt position in all conditions of the lungs in which much mucus was secreted. In April, 1866, a little child, three months old, after having suffered from slight catarrh for a few days, was seized with difficulty of breathing at night. When I arrived in the morning the child was livid, the eyes sunken and half closed, and the pulse remarkably slow, feeble, and irregular. The child breathed with great difficulty, and had a loose mucous cough, feeble and ineffective. The quantity of mucus in the chest was so great that the child could not inspire, and appeared dying. It was turned on the right side, ammonia applied to the nostrils, and ten drops of brandy administered every quarter of an hour. On the following day it breathed with greater ease, the expression had improved, and the pulse, though still slow, had a little more power. The air now entered the left side freely, and the râles were few; no breathing at the right side. The child gradually recovered, but for several days there were bronchial breathing, and bronchial voice on the right side. Before the child was turned on the right side there was no difference on auscultation between the two sides.

In bronchitis generally, and especially in the bronchitis of the old, I endeavour to leave one lung free for breathing, and then, as vital power returns, the position is gradually changed.

In the *convulsions* of children there is often a large flow of saliva and secretion in the bronchial tubes. This becomes immediately churned into foam, and greatly impedes respiration. In the lateral position all this drains away, the breathing is freed, and I have often seen recovery commence immediately.

In *epilepsy* the fit will often cease at once by removing stertor, but here it requires a little more management than

placing the patient on his side, for the spasms of the mouth, tongue, and fauces require opposing by little mechanical contrivances.

In May, 1866, I was sent for to a phthisical patient, who was said to be dying from hæmorrhage. I found him lying upon his back, partially elevated by pillows, and apparently breathing his last. His face was cold and ghastly, his jaw dropped, and his eyes widely opened and staring. He made a few unsuccessful efforts to inspire, when some large mucous râles were heard in the trachea. The pulse could just be felt feebly flickering. He was immediately placed well over on the right side, and ammonia was applied to the nostrils. A little brandy-and-water was introduced into the mouth, but there was no effort to swallow. A handkerchief was, however, soaked in brandy, and a portion left in the mouth. The mouth and tongue were quite cold. In a minute or two the respirations became longer, and air could be heard entering the uppermost lung, but none entered the lower. Gradually the râles diminished in the upper lung, air entered more freely, and the percussion sounds became more resonant. Consciousness, which had been utterly lost, gradually returned, and by the following morning he was perfectly himself, and could have transacted any business. He lived four days, breathing with one lung only.

On our arrival my friend Dr. Lewis, who was with me, was so convinced that death must take place immediately that he thought all our efforts to prolong life would be useless and unavailing.

On the subject of drowning I do not propose to consider the various modes of resuscitation, but to comment merely upon the fluid contained in the lungs of drowned persons. The Committee of this Society on Drowning came to the conclusion "that it was the entrance of fluid into the lungs, and the effects thereby produced, which was the cause of death in drowning." Professor Caspar, as a result of his prolonged researches on drowned persons, asserts that as a rule water exists in the lungs in the form of fine vesicular foam, even in those who have never come to the surface after once being submerged.

In 1861 a woman who had been taken out of the Serpentine and treated by the hot-bath at the Receiving-house was brought to St. George's Hospital about one hour afterwards. Mr. Jones, the resident medical officer, states that on admission "her breathing was fair, with loud rattling noise; her lips were livid, her pulse *very good*, her surface and extremities very cold; she was sensible and able to speak." Warmth and appropriate measures were employed, but in half an hour Mr. Jones was suddenly summoned, and only arrived to see her draw her last breath. The Marshall Hall method was immediately employed for half an hour, without the slightest signs of recovery, *but a large quantity of frothy fluid* came from the mouth. At the post-mortem examination next day, it was reported that "both lungs contained an immense quantity of frothy fluid, the bronchi were filled with fluid and injected." In this case the lungs were loaded with and paralysed by water. There cannot be a doubt that the Marshall Hall method would have unloaded the lungs, but I cannot doubt, also, that had she been placed on one side on her arrival at the hospital the upper lung would have cleared and acted quite sufficiently to sustain life. A lung containing frothy fluid does not clear immediately; the bells of foam must become gradually condensed and ooze slowly away, and to assist this nothing is more adapted than the Marshall Hall method.

Dr. Trollope of St. Leonards-on-Sea was called to a man who had been taken out of the sea. The man could speak a little, and vomited a quantity of water; but he rapidly became worse, insensibility came on, the breathing was slow and faint, and the pulse flickering.

The Silvester method was being used, and Dr. Trollope persisted in it for some few minutes. "Meanwhile," Dr. Trollope reports, "his respiration had ceased, beyond a slight mucous rattle in the windpipe; his heart's action could not be felt; jaw clenched, and lips livid. I then, finding these alarming symptoms supervening in spite of the persistence in Dr. Silvester's method, immediately had recourse to Dr. Marshall Hall's prone and postural, or 'ready,' method, and was gratified to find fluid escape from the mouth each time the body was laid on the chest, and respiration gradually set up, commencing with long-drawn respirations, or rather gaspings, at intervals. I persevered in the prone and postural movements for three-quarters of an hour, till respiration was thoroughly and satisfactorily established. The man then again vomited between a pint

and a quart of water, and was afterwards able to swallow a few tablespoonfuls of tea, and went on satisfactorily."

In March, 1862, I was called to a man who had been knocked into the sea by a heavy chain. It was calculated that he had been under water three minutes. On getting him ashore he was believed to be dead, but one of the men thought "they ought to get the water out of him," and so proceeded to roll him from side to side, and whilst this was done, a quantity of water was expelled from the mouth, and they perceived some attempt at breathing.

A few minutes after this I was on the spot, and found the man apparently dying, making occasional and feeble attempts to breathe, with a very feeble and irregular pulse. He was lying on his side with his head upon a coat, and a quantity of froth tinged with blood lying on the coat in the neighbourhood of his mouth. I observed that clear water and froth welled out of his mouth at the end of every inspiration. Active friction of the limbs, hot bottles and bricks, were carefully applied, and ammonia to the nostrils. Nearly an hour elapsed before we thought it possible he could live. He then began to moan, and in a short time a small quantity of brandy was swallowed.

In July, 1864, a man was capsized in a boat at sea. After being in the water some time he was picked up and rowed ashore. On arrival he was cold and livid, but breathing with great labour. He was immediately turned on his side by the coastguardsmen, and a quantity of frothy fluid came from the mouth. He was taken to an inn, where he was kept on his side, and where I saw him a quarter of an hour afterwards. He was then breathing with difficulty. A fine white froth, almost like milk, was oozing from his mouth and nose; his face was very livid, and meaningless in expression; his breath was cold; the limbs and body generally were almost stone cold; the pulse could not be felt. There were a few moist râles in the left side of the chest, the side which was uppermost, but the breathing was tolerably free; the breathing on the side upon which he lay was very feeble and obscure, and moist râles more abundant. He could not be roused. In half an hour he became a little restless, and then vomited a quantity of water. The pulse could now be felt, but not counted; this gradually improved. Attempts at vomiting supervened, and occasionally a partial restoration to consciousness. After another attack of vomiting, the pupils, which had been widely dilated, became contracted, and he went off into a sound sleep. He passed a most trying night from restlessness, and pain at the epigastrium; and the next day he was still livid, but better and easier. The following day pleuro-pneumonia of the right side (that which was downwards) supervened. From this he slowly recovered.

There are many interesting details connected with these cases of drowning which for brevity's sake I omit; but the cases, I hope, illustrate sufficiently that in drowning there is *some* fluid in the chest, and that all methods of resuscitation which do not provide for the removal of this fluid are utterly valueless. For my own part, my increasing experience only tends to prove that there is as yet no known method equal to that of the Marshall Hall method.

Independently of its effect upon stertor, "position" has a direct influence in many conditions allied to the apoplectic, such as chloroform poisoning, drunkenness, &c. &c.; and I have observed that in cases of great exhaustion the change from the back to the side is accompanied by immediate and great relief; the breathing, from having been carried on with evident effort, has become at once peaceful and easy.

During sleep, when the vital powers are resting, it is not the *back*, but the *side* which is selected as Nature's position; and I believe the explanation to be that on the back the diaphragm has to lift the liver and abdominal organs with each respiration, whereas on the side—especially the right side—the liver lies practically on the bed, and the diaphragm can do its work without oppression.

The general conclusions which may, I think, be fairly deduced from the present communication are:

1. That a "laryngeal stertor" may be added to the three forms I formerly defined.

2. That the three forms of stertor which have a most important connexion with the apoplectic state are the palatine, pharyngeal, and mucous stertor.

3. That these three varieties, whatever their remote cause, are the immediate result of a local mechanical condition—a condition which may always, and at once, be changed, to the great relief of the patients, and sometimes to their permanent recovery.

4. That it is necessary to keep the patient on one side, and that the paralysed side should be downwards.

5. That mucus and other fluids gravitate into, and fill up, the lower lung; and therefore that if the sides be reversed the mucus will find its way into the opposite lung.

6. That the fluid, crossing from the large bronchi of one lung to those of the opposite, becomes churned into foam, and causes dangerous obstruction to the respiration.

7. That the lung is not injured by remaining inactive and filled with mucus for a long period.

8. That these principles apply to all conditions in which mucus or fluid exists in the lungs, and also to all conditions allied to the apoplectic, whether there be mucus or not.

Folkestone.

THE ETIOLOGY OF CANCER: STATISTICS AND REMARKS.

By HERBERT L. SNOW, M.D. LOND.,
SURGEON TO THE CANCER HOSPITAL.

IN our present state of helplessness as regards the therapeutic treatment of malignant disease, any information tending to throw light on the origin of that class of maladies may (as a step in some measure towards their prevention) be deemed not unworthy attention—the more especially as I think very undue weight attaches (in the public, and even in the professional, mind) to some causes; while others are unfairly depreciated. I therefore venture to submit some statistics, taken chiefly from the records of the Cancer Hospital during the past two years; with the deductions which these seem to me to warrant.

1. *Hereditary tendency.*—Of 146 cases of uterine cancer there was some history of malignant disease having occurred in at least one other member of the family in 12 instances, with 7 very doubtful ditto. Of these 12, 4 patients reported relatives dead of the same disease; 3 of breast cancer; 2 of cancer in side (whatever that may mean); while in 3 cases the site could not be ascertained. Of 205 cases of cancer of the breast, there was a more or less credible family history in 27 instances; 6 more are marked doubtful. Of those 27, in 11 cases the mother, sister, or aunt had died of the same complaint (in 4 the mother, in 1 the mother and grandmother); 2 were stated to have died of uterine cancer, 2 of hepatic ditto. One relative (father) had died of cancer of the lip; 1 (grandmother) of cancer of the mouth: these affections being so invariably due to local irritation, I have no hesitation in excluding the cases altogether from the calculation. Again, 1 patient stated that her father had died of cancer of the breast; considering the rarity of such cases I think her statement must be regarded with doubt. In 13 cases the statement was confidently made that relatives had died of cancer, but the site was unknown. Thus of these latter cases we can only (with some show of reason) regard 15 as occurring in families where the disease might be hereditary. Taking the whole number, we find that in breast cancer hereditary tendency occurs in 13·17 per cent.; but, with the above deductions, in only 7·31 per cent. While in uterine ditto the percentage amounts to 8·21. Now, I conceive the only inference we can possibly draw from the above is, that if hereditary tendency to cancer has any predisposing influence whatever in its causation, such influence is of the very slightest, and in practice had much better be ignored altogether, as tending to mislead rather than to assist. Not long since I saw an unmistakably adenoid tumour removed from the breast of a woman, three members of whose family were stated to have died of cancer. I much doubt whether the small percentage recorded above would not be equalled by taking as many hospital patients at random, and inquiring as to the occurrence of cancer in their families.

2. *Injury.*—Of 143 cases of breast cancer, in which special inquiry was made as to preceding injury, 32 patients returned an answer in the affirmative, or 22·37 per cent.; while 12 gave doubtful replies. Among the uterine cases the idea of injury from external violence is necessarily almost excluded, yet 4 attributed their disease to falls or kicks, while many dated it from a confinement or miscarriage. Among the 205 breast cases quoted above 3 occurred in males, and in these it is noteworthy that 2 attributed their disease, with every appearance of probability, to blows, while the third gave an obscure history of injury. There can be no doubt that

mechanical injury is a real exciting cause of malignant disease; but (except in epithelioma) the frequency with which the latter so arises is greatly exaggerated, both in medical text-books and in the public estimation. I must here point out one source of fallacy; women very frequently present themselves, within a week or two after some injury, complaining of severe pain in the breast, and in a state of the greatest alarm;—and only recover their equanimity after a lapse of many months, coupled with repeated assurances of immunity from cancer. By these cases I am led strongly to consider that in many instances the blow originates the cancer, not *directly* but *indirectly*, by producing mental depression, and by concentrating the attention on the part affected.

3. *Nervous depression (especially mental trouble).*—Of 103 uterine cases in which preceding causes of mental or physical nervous depression (trouble, or very hard work) were sought for, 55 gave a history of preceding mental trouble (often combined with hard work), 10 of hard work alone, while 10 gave doubtful replies. Of 38 breast cases 24 patients gave a history of sorrow and anxiety, 4 of hard work, while 1 case was doubtful. Thus of the breast cases (although I must confess the number specially investigated in this connexion is smaller than I could wish), 73·68 per cent. gave an account of nervous depression, either mental or physical, immediately preceding the appearance of the disease, while in the uterine cases the percentage amounts to 63·1. From this I cannot help inferring that sorrow, anxiety, and hard work are very powerful factors in the production of malignant disease. The following case, in its exclusion of every possible cause of cancer save one, I regard as so typical that I cannot forbear relating it here; it is not included in the above 38. A lady aged forty, wife of a gentleman in comfortable circumstances, strong and previously healthy, leading an easy life, with no family, having a cheerful disposition, without family history of cancer, and never having sustained any injury, became greatly affected at the death of her brother after a short illness, and allowed this to prey on her spirits for some time afterwards. Within a few weeks a small lump appeared in her left breast; she paid no attention to it till six months afterwards, when, on examination, there was found a well-marked scirrhus tumour, with enlarged axillary glands.

I have above confined my remarks to malignant disease when affecting the breast and uterus, both as affording the largest number of cases for comparison and as practically the most important. I may add that, of 7 cases of rectal cancer, 1 gave a doubtful history of hereditary taint; 24 of cancer of lips; tongue, face, or mouth, give 4 instances, and 2 more very doubtful; 21 ditto of vulva, vagina, and other parts, give 2 instances. Epithelioma, wherever it occurs, is almost invariably (if not always) due to continued mechanical irritation. Nearly all the cases in which the lip, tongue, or mouth were affected could be traced to the irritation caused by a projecting tooth, or by a pipe-stem; and where these factors were absent the disease often originated at or near the angle of the mouth, where any little fissure would naturally be kept open by the motion of the parts. Two patients with epithelioma of the lip dated their malady from a piece of flesh being torn out during the extraction of a tooth; one, with epithelioma of the vulva, from a fall on the edge of a piece of board. So-called "ichthyosis" of the tongue, of course, is very apt to end in epithelioma. In 12 out of the 205 breast cases, both breasts became implicated. One case only was supposed to have followed "eczema" of the nipple.

Although I have not yet been able to procure a sufficiently large number of cases for comparison, I submit there is a strong probability that what is here affirmed of mammary and uterine cancer is also true of malignant disease (excepting, of course, epithelioma) wherever that may be situated. And I now beg to recapitulate the principal conclusions to which, I conceive, the foregoing statistics point:—

1. Hereditary tendency, as a predisposing cause of cancer (at all events, of mammary and uterine cancer), is almost valueless, if not entirely so; and in practical diagnosis should be altogether ignored, as misleading.

2. Mechanical injuries directly produce cancer in a certain percentage of cases; but this percentage is small.

3. As direct and immediate causes of cancer (especially, in my own experience, of uterine cancer), mental trouble and hard work are very potent agents; and exert more influence than any other antecedent within our present knowledge.

Bayswater, W.

THE CURE AND CARE OF THE INSANE.

By ROBERT BOYD, M.D., F.R.C.P.,

LATE SUPERINTENDENT OF THE COUNTY SOMERSET ASYLUM.

(Concluded from p. 935.)

THERE is abundant proof in the annual asylum reports of the visitors and superintendents throughout the kingdom that the Pauper Lunacy Acts hold out a premium, as it were, to the manufacture of lunatics, by enabling the parochial authorities to get rid of their troublesome, helpless, infirm and aged paupers, and thus crowding asylums with improper objects, instead of providing for them in the unions.

As the sick ward of the union is the basis of all care for the sick poor, and insanity is so frequently the result of bodily ailments, the laws regarding medical relief and pauper lunacy should be amalgamated. The county asylums have gradually become union infirmaries by the withdrawal of epileptics, idiots, paralytics, and infirm and aged persons; while by placing the workhouse infirmaries under the control of the visiting justices and commissioners in lunacy, the expense of further additions to asylums would be saved to the ratepayers, and a beneficial classification of the patients could be obtained. Within a distance of four miles from the Somerset Asylum was a workhouse not many years built for 440 inmates and containing eighty persons only, though the asylum was over-crowded and more room required.

In my annual reports the connexion between mental disorder and bodily disease is frequently reverted to. In an analysis of the causes of the first two thousand cases of insanity in the 17th Annual Report, page 28, it is shown that about one-half depended upon bodily or physical causes. Would it not be more rational to treat diseases with more care at the earliest stage, before delirium supervened, before the sufferers were beyond relief, or incapable of appreciating the efforts to restore them to health? Are they less objects for care and sympathy when suffering from sickness or accident, before being deprived of reason than afterwards? And would not measures taken at the outset have prevented much suffering, been more useful, and, perhaps, saved valuable lives from becoming mentally total wrecks? A poor man in writing to express his gratitude, concludes with this trite and significant observation, "poor people does be lost for want of means when they are sick."

Under the Poor Law the system is how to avoid relief to the poor in sickness, for the relieving officer is told that medical relief being the stepping-stone to other relief should, if possible, be avoided. Is it, then, to be wondered at that, under such a system, workhouses are comparatively empty, whilst asylums, which have been constantly added to, are still over-crowded, and insanity supposed to be increasing? This is becoming a national disgrace. The health of the poor is of the highest importance to the State, as it is from their ranks that our labourers, soldiers, and sailors are supplied. The greater evil to contend against amongst the labouring classes is intemperance; it too often brings whole families to the workhouse, and about 15 per cent. to the asylum.

In visiting the Salpêtrière in Paris it reminded me of the Marylebone workhouse, but was on a much larger scale, containing between five and six thousand female poor, including the infirm sick and insane, who are all treated as the circumstances of their cases demand. The Bicêtre, a smaller but similar institution for the male poor, is situated in a different part of Paris. M. Fabret, physician to this large hospital of Salpêtrière, states in his book, that after several years' research into the morbid anatomy of insanity, and after failing to elucidate the nature of the malady by the aid of facts so gained, he next attempted to interpret the nature of mental disorders by recourse to the doctrines of psychology, especially those of Scottish metaphysicians, for fifteen years, but at the end of that time had to lament that his labour was all vanity and vexation of spirit. My own experience of upwards of thirty years, and after having made post-mortem examinations of nearly every case that died in the Somerset Asylum from 1848 to 1868, and previously of more than 2000 in the St. Marylebone Infirmary (the results of which have been published in the Philosophical Transactions for 1861, and Willis's translation of Wagner's Physiology, p. 669), agrees with that of M. Fabret as regards the morbid anatomy of insanity. It was found that the average weight of the brain was greater in the insane than

in the sane, that the weight differed in various forms of insanity, that the left cerebral hemisphere was usually heavier than the right, especially in epileptics, and that the spinal cord was usually diseased in cases of general paralysis, the most fatal form of insanity in males. The difference in weight between the whole brains of the sexes had been previously observed, and the age at which it arrives at its maximum weight.

Workhouse infirmaries might be made most useful auxiliaries to hospitals for extending the means of clinical instruction to pupils at the bedside, which has become so essential to candidates for final examination in their knowledge of medical diagnosis and treatment; provided always that those infirmaries were no longer under the control of persons annually elected, but under visitors with power to carry out a liberal provision of food and medicine for the sick poor generally.

Dr. Babington has observed "that the mind and the body reciprocally and mysteriously affect each other, and in some maladies are so intimately connected with the disordered state of both that it is often difficult to determine on which they more essentially depend, or which they more seriously influence."

By some of the most eminent writers on insanity, as Pinel and Esquirol, the causes are considered primarily to depend on derangement of the digestive functions, and frequently to be connected with tubercular disease of the lungs. In other words, that insanity is the delirium of chronic bodily disease. If so, it would appear an argument in favour of placing the sane and insane on an equal footing as regards nursing and medical comforts, as in France, where there are no poor-laws, and the rule is insisted on in the distribution of relief, "that misfortune does not obliterate shame or destroy self-respect, and that one of the most important duties is to succour the unfortunate without causing them a blush."

The neglect of the sick poor, aged, and infirm in workhouses was frequently alluded to in the annual reports of the Somerset Asylum, and the necessity of placing them under the same kind of treatment as the insane poor insisted on.

With respect to private patients, numerous applications were made by persons for the reception of friends unable to pay the charges of private asylums. By the late Lunacy Act facilities are given for receiving this class of patients into county asylums. The intercourse of private with pauper lunatics is not desirable; the private patient becomes discontented, and renders the others so. During the acute stage of mania no inconvenience would be experienced by associating the two classes of patients. Regarding county lunatic asylums as hospitals for the treatment of insanity in the acute stage, how far might they be made available for patients of both classes, provided that, after the acute stage, the patients could be removed to asylums suited to their relative conditions of life?

It has been suggested that it would justify proceedings and afford time for the friends to make their arrangements, without injury to the patients, if all cases, not found lunatic by inquisition, were sent at once for curative treatment to the county asylum. Slight alterations in county asylums might be sufficient for such a purpose.

It has been my endeavour here to show, in the first place, that the Pauper Lunacy Acts might advantageously be abolished in favour of Medical Relief Acts, to include all cases of the poor, whether visited by sickness or insanity, without the stigma of pauperism being attached.

2ndly. That the workhouse infirmaries should, like asylums, be placed under the control of visiting justices and the commissioners in lunacy.

3rdly. That the Workhouse Infirmaries should be made available for the instruction of medical pupils and general practitioners.

Finally, and above all, it cannot be too urgently insisted on that the action of the Legislature is much needed to provide measures for the admission to and retention in lunatic asylums of none but proper cases; and that due means should be adopted for the safe keeping of harmless and incurable cases, apart from those which may admit of cure. When this desirable object has been attained, no doubt the number of recoveries will be largely increased, and by this advance in humanity the expenses diminished.

These remarks are not intended to apply to the metropolitan district, in which, under the Local Government Board, the chronic cases of insanity and the idiots have been provided for.

Bolton-row, Mayfair.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et merborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium

WANDSWORTH INFIRMARY.

CASE OF PURPURA HÆMORRHAGICA; DEATH; NECROPSY.

FOR the following notes we are indebted to Mr. James Allan, assistant medical officer.

Catherine W—, aged twenty-one, was admitted on September 15th. She had been married for three years, and had suckled her only child fourteen months, up to onset of illness. The menstrual function had not been re-established since delivery. During her married life she had worked hard as a laundress, and was so occupied until lately. Her meals had been taken irregularly, and the food was of poor quality and not always sufficient. Once, at the age of twelve, she had blood-spitting, and she had a brother "delicate in the chest."

Three weeks before admission pain was experienced in the left knee-joint, which caused her to limp. She continued at work till September 2nd, when she had pain in the left hip. She lay in bed with the knee flexed, and had a rigor. She suffered from sleeplessness, loss of appetite, and great thirst; did not perspire, but became thin. The bowels were confined.

On the 14th she spat up a large quantity of blood; the bleeding recurred next day, prior to her being taken to the infirmary. Before the hæmoptysis there had not been cough or any other chest symptom.

When examined after admission the patient was very pale, and rather thin; the hair and complexion were dark. There seemed to be acute pain in the left hip, knee, and limb generally. An expression of pain was elicited by pressure over the sacrum and lower lumbar region, along the left sacro-iliac joint, in the left groin, and on tapping the left iliac crest. The left knee was not tender or swollen, and was of the same temperature as the right. The skin was dry and harsh, and presented numerous small ecchymoses all over the body and limbs. Examination of the chest detected nothing abnormal, except over a limited area at the base of the left lung posteriorly, where there was crepitation with inspiration. Temperature in axilla 101.5°; pulse 100. Pain and excitement were quieted by the administration of opium.

On Sept. 17th she had copious hæmoptysis, the blood coughed up consisted partly of clots. After free use of ergot internally the hæmorrhage stopped, but not readily; spray from a solution of sulphate of iron was inhaled; the patient also took small pieces of ice into her mouth. Temperature in the evening 100°. A little brandy was ordered on account of faintness.

On Sept. 22nd several dark, bruise-like patches, of considerable size, were visible on the back in the lower lumbar and sacral regions. The seat of a similar patch on the left forearm was acutely painful for about twenty-four hours before discoloration took place. The small spots on the body were getting larger and purple. There was no expectoration. An aortic systolic bruit was detected. The patient was delirious during the night; the skin was dry, tongue pale, dry, rough, not coated; and there were sordes on teeth. Morning temperature 102.2°; pulse 120. Evening temperature 101.8°. Ordered quinine and digitalis; diet as before. She was restless, but not in pain; thirst was great.

On Sept. 24th she had subsultus tendinum. Morning temperature 101.2°; pulse 120. Evening temperature 101.2°; pulse 120.

She died at 3 A.M. on the 25th. Hæmorrhage had not recurred since the 17th; food taken readily throughout.

Necropsy twelve hours after death.—On the cutaneous surface there were numerous purplish macule, fewer on the posterior aspect of body and limbs than anteriorly, none on the face. The spots were round, and from one line to one and a half lines in diameter. Section showed these to be

due to extravasation of blood in the skin. Several dark patches of considerable size, irregular in outline, resembling recent bruises, were situated on the lower part of the back, one on the right thigh near the groin, and one on the posterior surface of the left forearm, near the wrist; these depended on subcutaneous extravasations. There was not much subcutaneous fat; the manubrium sterni was cut through transversely without difficulty by a strong knife. The pericardial sac contained half an ounce of yellowish serum. There were numerous extravasations on the heart's surface beneath the visceral pericardium—small, rounded, varying in size from mere points to spots a line in diameter. The right heart contained a large firm adherent yellowish-white clot, as well as some dark blood, very thin; the left heart was nearly empty, and had small white clots entangled amongst the chordæ tendinæ. The aortic arch was occupied by a thick, tenacious white clot. Under the endocardium of both ventricles there were minute extravasations, more numerous in the left. The aortic valve was slightly incompetent, the flaps were somewhat rigid, and there was atheromatous change around the commencement of coronary arteries. The heart, the left ventricle of which was hypertrophied, weighed 10 ounces. The right lung weighed 22 ounces, and was anæmic and highly œdematous throughout, but more markedly along the posterior border. There were several old, very limited pleuritic adhesions; no fluid in the right chest, nor subpleural extravasations. The left lung weighed 20½ ounces, and was œdematous, but there were no adhesions. At the base of the lower lobe, posteriorly and involving a limited area, a portion of lung, pyramidal in shape, besides being œdematous had a blood-stained appearance externally and on section; the lung tissue was not broken down, the bronchi of this part were full of dark clotted blood. There was about an ounce of reddish serum in the left pleural cavity. The intestines were remarkably pale, blanched, and distended with flatus. The stomach was also distended, and a small patch of its mucous membrane near the cardiac orifice had undergone post-mortem digestion to a slight extent. The intestine presented no lesion; contents were thin, yellowish. The mesenteric glands were larger than normal. The spleen was large, weighed 12½ ounces, was firm, and purplish on section. The liver weighed 57½ ounces, bile-stained; under the capsule, over a considerable extent of right lobe on its upper surface, there was blood extravasated, and here the capsule stripped off very readily; section at this part showed that the liver tissue was infiltrated with blood to the depth of half an inch. The gall-bladder was empty. The right kidney weighed 5½ ounces, the left 6½ ounces, the capsules were adherent, but there were no hæmorrhages; section under the microscope presented increase of intertubular tissue. The right suprarenal capsule weighed 63 grains, the left suprarenal 66 grains; the pancreas 4½ ounces. The bladder was pale and blanched, and there was a small number of minute submucous hæmorrhages. The uterus was small; length 2½ inches; weight, without appendages, 1½ ounces. There were numerous hæmorrhagic stigmata under the mucosa of body of uterus. Both ovaries were enlarged, right was 267 grains in weight, left 284 grains; both were freely movable; under the microscope they had the characters of a fibroma with several small cysts. The left hip-joint examined and found normal, also left sacro-iliac joint. The pelvic fascia posteriorly was thick and readily separable from the sacrum; between this fascia and the sacrum and ligamentous structure behind it there were numerous small hæmorrhages. The coccyx, sacrum, and contiguous part of left ilium had an unusually dark appearance on the surface; these bones were blood-stained on section, as were also the bodies of lower lumbar vertebrae. There was a hæmorrhage in the sheath of the left great sciatic nerve near its origin. Examination of the head was not permitted.

HOSPITAL SUNDAY AND SATURDAY IN THE PROVINCES.—At Gloucester the total proceeds of these collections amounted this year to £492 2s., being £110 less than in 1879. Some of the Church collections, however, have been deferred. The sum, less expenses, is thus divided: Infirmary, £257 1s. 6d.; Dispensary, £73 2s. 7d.; Children's Hospital, £72 15s.; Eye Institution, £73 12s. 7d.—At Hull the sum collected was £657 8s. 8d. (against £679 17s. 5d. in the previous year); distributed as follows: The Infirmary, £455; the Dispensary, £80; Children's Hospital, £55; Homœopathic Dispensary, £20.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

THE last ordinary meeting of the Pathological Society for the year was held on Tuesday, the 21st inst. ; J. Hutchinson, Esq., the President, in the chair. Dr. Drewitt exhibited a living example of late rickets, which some of the members of the Society considered to differ in many points from the more usual form of the disease. The debate on rickets was then reopened by a very suggestive speech from the President, and continued by Mr. Lucas ; Dr. Baxter, who made a valuable addition to the facts of the etiology of rickets ; Dr. Barlow, who spoke of the disease misnamed fetal rickets ; Mr. Shattock, and others. The meeting was prolonged beyond the usual hour, and it was late when Dr. Fagge, in a few sentences, closed the debate. Dr. Lees and Mr. Pearce Gould were appointed auditors of the treasurer's accounts, to be presented at the ensuing general meeting of the Society.

Dr. DREWITT showed a boy ten years and eleven months old, a patient under Dr. Cheadle's care at the Hospital for Sick Children ; one of six healthy children, none of whom suffered from rickets. Up to eight years of age he was well, and played about like others of his age ; but a month later he complained of aching pains in his legs, and he had to be carried to and from school, and all his bones began to bend. On admission to the hospital he was worse than at the present time ; his femora, tibiae, clavicles, and ribs were especially bent. There was great tenderness of the subcutaneous borders of the tibia and ulna, enlargement of the ends of the bones, and troublesome cough. Under good diet and cod-liver oil he rapidly got worse, but when taking eight grains of iodide of potassium three times a day he quickly improved, the tenderness of the bones disappeared, and his cough left him.—The PRESIDENT asked if the cod-liver oil was discontinued when the iodide of potassium was given, and whether it was the brown or the pale oil that was used. It was a remarkable case, and especially interesting in that anti-syphilitic remedies had done good when cod-liver oil had failed.—Mr. GAY asked for particulars of the family history of the lad.—Dr. DREWITT replied that there was no history of syphilis in the mother, who was healthy. Some of the children had had infantile thrush. The cod-liver oil was discontinued while the iodide was given.—Mr. ADAMS remarked that the case differed from ordinary rickets ; the femora were very shortened and greatly bent, but the tibiae were hardly bent at all ; the forearms were bent as if from crawling. He thought it a transitional form between rickets, mollities ossium, and osteitis deformans.—The PRESIDENT requested Dr. Fagge, Mr. W. Haward, and Dr. Drewitt to report upon the true nature of the case.

The debate on Rickets was then resumed.

The PRESIDENT.—First, I have to express a shade of regret that the debate, interesting and instructive as it has been, has not produced more in the form of pathological evidence. It may be that this evening will somewhat confuse this criticism, otherwise I think we have all of us noted that in the main it has consisted in the interchange of opinion rather than the citation of new facts. I may be asked, perhaps, what kind of facts I should have liked. Well, in reply, I should have liked definite information as to the state of the urine in rickets, and possibly the state of the blood also. Further and more extended chemical analyses of the bones at different stages of the complaint also seem desirable. Additional facts as to rickets in the lower animals, with specimens, are wanted. So also with rickets in the foetus and congenital rickets. Lastly, I should much have liked to know from careful observation whether the state of the teeth, carefully distinguishing between the first and second sets, is, or is not, modified by rickets. Amongst the parts of the subject most fully entertained in this discussion has been the relationship which exists between inherited taint of syphilis and rickets. Dr. Fagge in his opening address asked "whether syphilis may not be one of the causes of rickets," and Drs. Barlow and Lees

have presented us an excellent report, which supports to some extent the contention of M. Parrot that the cranio-tabes formerly supposed to be due to rickets—and with it some other lesions—is really due to syphilis. It is now long since we have known well that many of the malformed foreheads, most of the malformed teeth, and many cases of bent and enlarged bones, formerly considered to be of a rickety nature, are really syphilitic. The explanation of the precise cause of the deformity in the syphilitic skull has, however, been reserved for M. Parrot and Dr. Taylor, and to them we owe our present knowledge that in infancy the osseous system is often very extensively affected by a transitory form of inflammation. The skull bones and the long bones alike suffer, and the epiphysal ends are especially prone to be severely attacked. There remains, therefore, I think, no doubt whatever that in congenital syphilis a state of general periostitis is very common, which may easily be thought to resemble rickets. The child is in pain all over, and the joint ends of the bones are swollen and tender. In this condition the flat bones become vascular and soft, and it is difficult to withstand the evidence in favour of the belief that not only may they thicken, but that, under special local influences, they may atrophy and suffer local absorption. The influences which localise the thinning may be either external or internal, pressure of the brain or pressure of the pillow. If we regard the symptom named "cranio-tabes" as simply local absorption of soft bones from pressure, may we not easily admit that it is probably common both to syphilis and rickets ? Each of these diseases in its own fashion makes the skull bones vascular and soft, both make it painful for the child to move, and thus favour the occasion of injurious pre-sure. We need not, I think, go so far as to believe that syphilis is "a cause of rickets," but may rather prefer to say that syphilis may on its own account produce conditions which simulate those of rickets ? Is it not probable that to the skilled and careful observer there will in most cases be found grounds for a differential diagnosis between rickets and syphilis, and that too both in the ward and the post-mortem room ? That the two often co-exist and run their course together, is highly probable ; but that they are essentially and totally distinct, being induced by wholly different causes, will, I think, be the verdict of all who have listened to this discussion. Surely those who confuse them, or who think that rickets apart from syphilis has no existence, commit a grave clinical error. I was glad to hear Sir William Jenner's defence of the term diathesis as applicable to the state of health which induces rickets, and his refusal to allow that word to be restricted by any arbitrary definition. If we are to understand by diathesis a condition of defective health, giving during a long period proclivity to special forms of disease, then undoubtedly the rickety state is a diathesis. If, on the other hand, the term is to be restricted to the results of a specific poison, then it is not. But the latter is not a very successful employment of the word. Just in the same sense as we have a scorbutic diathesis, a tubercular diathesis, a gouty diathesis, and a leprous diathesis, so we have a rachitic one. It is merely a question as to the use of the word, and those who object to it in this sense will perhaps kindly supply us with a better. Not only, however, do I contend that the rachitic state is correctly included with the diatheses, but I wish to ask Dr. Fagge very definitely whether there are any good reasons why it should not be placed with confidence in one class of diatheses. I allude to that class which may perhaps be conveniently known as "diet-diatheses," or assimilation diatheses. In this class are to be grouped, with others, scurvy, gout, pellagra, and in my opinion leprosy, all due to some error in diet or assimilation. It is very important to bear in mind respecting all of them, that although usually the cause is defect or excess of some food element, yet that precisely similar results may ensue from defective assimilation or excretory functions. The effects of food, both negative and positive, are always relative to digestive capacity ; it may be due to the idiosyncrasy of the individual, and thus the somewhat vulgar saw as to meat to one and poison to another becomes a very literal truth. I would not insist upon this most obvious fact were it not that I think that a forgetfulness of it has done much to put us into a mist as regards the real causes of rickets and the maladies associated with it. Because defective food supply cannot in all cases be proved, it is hastily assumed that rickets is not a diet disease ; and those who think it hereditary, consider that its hereditariness points to the same conclusion. Dr. Fagge quoted a German

authority (Vogel) as insisting on its hereditariness, and saying not a word about food as a possible cause. But is not gouth hereditary? and is not gout distinctly a diet disease? I would quote leprosy as an equally strong instance, but that the facts respecting it are not so well admitted or so widely known. There is nothing inconsistent in the fact that a tendency to disease produced by diet should be hereditary. It is the organs of assimilation which are inherited. Through their peculiarity the effects of unsuitable food may be greatly exaggerated, or even the most wholesome may prove non-nutritious or injurious. The arguments which have been thought to invalidate the hypothesis of a diet cause for rickets have been held to have yet heavier weight in the case of osteo-malacia, or mollities ossium. It occurs to those who have full choice of their food, and under conditions in which it is impossible to suspect any ordinary deviation from sound rules of diet. Yet may it not be, after all, that it is an instance of defect in assimilation? I wish especially to elicit Dr. Fagge's opinion on this subject. Mollities ossium is on the Continent known as "rickets of the adult," and Trousseau in particular devotes an able lecture to the attempt to prove their identity. Yet I think we may note amongst ourselves a decided willingness to avoid this subject, and to admit that nothing whatever is known as to the real nature and relationships of mollities ossium. In the present discussion it has, I think, scarcely been mentioned. Dr. Gee told us that if a child is not rickety at a year old, it may be assumed that it will not become so. Other speakers, and amongst them definitely and emphatically Sir Wm. Jenner, have extended the period of liability; but none, so far as I have heard, have hinted that it is a liability which extends through life, and is probably almost the same in kind, though modified in its results by age, and other circumstances. Amongst the arguments which Trousseau mentions in support of the identity of rickets and osteo-malacia is the fact that they are curable by the same remedy. He is a firm believer in cod-liver oil as the best means of curing rickets, and he records a most remarkable case of advanced mollities ossium in which the patient was most definitely cured by its use. Surely we have, in such facts, not only support for the belief in their identity, but also in the theory of their being both due to defective assimilative power. Let me, in parenthesis, say that Trousseau insists that the oil must be the brown, unpurified kind. It is just possible that in the general substitution of the purified kind in English practice is one explanation of our diminished faith in the oil as a specific for rickets. If we assert that rickets is essentially a food diathesis we by no means exclude from the list of its causes such influences as cold, deficient clothing, bad ventilation, and the like. Nothing is more certain than that one and all of these may help to disorder the organs of assimilation, and prevent the perfection of digestion. Alone, however, none of them would, excepting in the hereditarily predisposed, be efficient in the production of rickets; whilst alone and quite unaided by them, defective food has been over and over again proved to be competent to that result. Defective food is then probably the main cause; defective assimilation in many cases helps the influence of defective food, and in a few cases accomplishes the whole task; the others are to be reckoned only as constituting and as helping chiefly to induce defective assimilation. If Dr. Fagge is not inclined to attempt the repetition of the diet hypothesis as the cause both of rickets in the infant and osteo-malacia in the adult, I have next to ask him whether it might not be convenient to somewhat modify our nomenclature, and place the series of related maladies in suitable juxtaposition of alliances. It is probable that peculiarities in the mode of life at different periods of life are the chief influences which modify the malady. We have perhaps the following: intra-uterine osteo-malacia, or congenital rickets; infantile osteo-malacia, or rickets of young children; osteo-malacia of adults; osteo-malacia of pregnancy; osteo-malacia of insanity; osteo-malacia of senility. It would be of much interest to say a few words in explanation of the different modes of manifestation assumed by the same malady at different periods of life, but time does not permit. I may just hint, however, that it is easy to explain both why osteo-malacia should be peculiar when it occurs to infants, and why it should be found in practice so overwhelmingly common in them in proportion to other ages. It is during the first year of life that absolutely no choice as to food is permitted, and that a sameness of dietary is attained which finds no parallel at any other. If the milk given to the infant be defective

there is no chance of escape, for it is probably the one sole article of food. The peculiarities of osteo-malacia of the infant are due to the fact that the bones are then still growing, and the cartilages unossified. At later periods no disease of epiphyseal cartilages is possible, since, for the most part, these have ceased to exist. - Dr. Fagge has drawn attention to the frequency with which symptoms of nervous disturbances occur in rickets, and has referred not only to the well-known deviations from the average in point of intelligence, but to hydrocephalus, chronic cerebritis, convulsive affections, tetany, &c. It is of not a little interest to those who believe in some bond of connexion between the two conditions to note that in adult life with certain forms of insanity osteo-malacia is constantly associated. In this instance, it has been conjectured that in some way the nervous system interferes with the nutrition of the bones. Is not the hypothesis far more likely that both the nerve centres and the bones share in a defect of assimilation, in existence probably for a long time, before any symptoms in either class of organs revealed it? It may help, probably, not a little to the full acceptance and computation of the diet theory of rickets if we emphasise an opinion expressed by both the opener of the debate and by Mr. Warrington Haward and others who have taken part in it. I allude to the belief that a large majority of cases pass unrecognised. So long as we think only of well characterised cases, so long are we likely to cherish a belief that the disease is, in some sort, a pathological entity, and due to some specific cause. If we break away from this notion and recognise what is probably really the fact—that we only diagnose exaggerated cases, and that a tendency to the same, or a slight degree of it, is present in thousands of patients to whom the term rachitis is never applied,—we become better able to realise that the malady, so far from being a specific disease, is not even a well specialised one. The same argument is applicable to the mollities ossium of adults. To put this idea in other words, it may be said that when a condition of defective assimilation in an infant rises to a certain point, and produces failure in the process of ossification, we name it rickets, and when a similar ailment in an adult rises to a certain height of severity and produces brittle bones we call it mollities ossium. For one infant who manifests the outward signs of rickets, and for one adult who shows those of mollities ossium, probably there are in each case a hundred in whom the tendency, in greater or less degree, and for longer or shorter time, is present. We recognise, name, and study only the severe and exaggerated examples. We must make a clear distinction between congenital rickets and hereditary rickets. The evidence which has been given that signs of rickety changes may be present in the mature foetus at birth by no means proves that there was in these cases an inherited disposition to rickets. As has been well observed indeed by Dr. Joseph Adams, congenital conditions of disease not seldom are hereditary. The mother is to foetus not only its progenitor, but its nurse during intra-uterine life. If rickets be a disease due to defective food and the mother's blood be in a defective condition, it may easily come about that, although the foetus originally inherited nothing, yet it may become rickety during its pre-natal period of life. A disease which is in a true sense hereditary, ought to be derivable indifferently from either parent—sperm or germ; but it is clearly possible that rickets may not be so. We must admit, I think, the evidence that rickets is occasionally congenital, the rarity with which it is so fits well I would submit with the hypothesis of its food causation, since we know that even from very feeble mothers the foetus often manages to obtain a supply quite sufficient for its full growth. It is very different when it comes to depend solely upon a single secretion, the milk of the same mother. As to the evidence of the transmission of hereditary tendency to rickets. I do not think that I have in this discussion heard any facts excepting the little fragment of evidence which I myself produced. In the case I refer to, Dr. Ormerod's, a father who had rickets in childhood and mollities ossium in adult life, had also two daughters who suffered severely from rickets. It is obvious that these children may have been themselves subjected to the ordinary food-causes of rickets, and that inheritance had nothing to do with it. I am unable to state anything as to their mother's health, or the management of their infancy. Still we may safely believe that there is nothing improbable in the idea of the hereditary transmission of a constitutional tendency to rickets—that is, to

speak definitely, of a tendency to defective function on the part of the organs of assimilation, which may, either with or without the help of contributory causes, at some time bring about such a defect in the composition of the blood as would interfere with the nutrition of the bones.

Mr. CLEMENT LUCAS.—I would not call rickets a diathetic but rather a dietetic disease; for though bad air, bad clothing, and general squalor and filth, together, perhaps, with certain constitutional states in the parents, may contribute to its production, there will, I think, be found in every case an insufficient or altogether injudicious diet. Has any gentleman present ever seen rickets without a distended abdomen? In my experience it is constant. The liver is rarely much enlarged; the spleen is very variable. I can show that enlarged spleen may be due to rickets without syphilis, and to syphilis without rickets, but the two spleens may be pathologically distinct. By far the chief cause, however, of the enlarged abdomen is the distension of the stomach and intestines with flatus, consequent on injudicious feeding. Children under nine months suffering from rickets will almost invariably be found to be bottle-fed, whereas children suffering from rickets at sixteen or eighteen months will often be found still hanging to the mother's nipple. In either case the diet is injudicious, and I will undertake to produce rickets in any child under three years of age that I may be allowed to feed improperly. As regards which child is most frequently attacked by rickets, my experience, in accord with what Sir W. Jenner said on the last occasion, was that the eldest child of the well-to-do and the later children of the poor which suffer most. The eldest child of the rich suffers because it is an experimental child, and the parents learn by practising upon it how best to feed those that follow. Dr. Fagge has shown, and I agree with him, that the younger children of the poor suffer because the parents are unable to provide sufficient food for them. He considered it could be and was hereditary in the sense of reproducing the rickety frame and a tendency to become rickety under the special favouring conditions. It was often asked why there was more frequent and greater enlargement of the epiphysis of the radius than the tibia. It is because rachitic children are four-legged animals, crawling about on hands and knees, that the wrists suffer and the ankles waste, but in children who walk upright I always find the ankles enlarged as well as the wrists; but here, again, rachitic children are continually falling, and then, as is a case in Colles' fracture, it is the lower end of the radius which receives the force of the concussion. For the same reason the beading of the ribs is a constant symptom, because the ribs are ever on the move. Another symptom to which I would allude is laryngismus stridulus. This is a local spasmodic affection found always associated with rickets. Must it not be due, then, to some local irritation of the recurrent laryngeal nerve? I think it not unlikely that the growing extremities of the tracheal rings will be found enlarged and pressing on the nerve, or possibly it may be irritated where it passes under the inferior cornu of the thyroid cartilage. If not here, the spot where it passes through the jugular foramen should be examined. It is so localised a spasm that it must be due to a local cause. No description that I have met with quite accords with my experience of the rachitic head. In the first place, it is a large head, and those who say that the head is not enlarged, but simply rendered disproportionate by a lack of development of the face, have fallen into error by including in the non-rachitic class heads which have been enlarged by antecedent rickets, the patients at the time of examination showing no enlarged epiphyses or other signs of rickets. There is a child now in the Evelina Hospital who has a remarkable head, but no enlarged epiphyses. I had some difficulty in persuading the house-surgeon and registrar that this was due to rickets till he stripped the chest and exposed a characteristic pigeon chest. There is also a boy in the hospital with most extensive rachitic deformities, on both of whose knees I have operated by Ogston's method. He is eight years of age, and has a head twenty-one and a half inches in circumference—more than an inch above the average. I got Mr. Hall White, the house-surgeon, to measure the heads of the children at present in the hospital. Of these seventeen show signs of rickets, and their average age being 4·72. Mr. White finds the average circumference of the heads to be 21·22. Comparing these with a similar number of non-rachitic children, Mr. White found, with an average age of 6·05, the average circumference was 19·95. The

rachitic head is peculiar. It is a long head and a broad head, but flat at the top. It invariably gives increased width between the eyes, showing that the base is increased as well as the vertex. In its most extreme form, it is composed of four convexities, like four scallop-shells articulated together, corresponding to the frontal, parietal, and occipital bones. The fontanelles are depressed, and remain depressed when ossification is complete. The antero-posterior ridge between the parietal bones, which is common in skulls, is absent in the rachitic skull, and a depression above a very convex occipital bone in the adult is almost characteristic of old rachitis. Thackeray's skull was undoubtedly rachitic. I could allude to very many others, and the rachitic head is not a thing to be ashamed of; indeed, he regarded it as a great good fortune.

Dr. BAXTER.—It was with a view to obtain some more exact notions as to the causation of the disease that I investigated upwards of a hundred consecutive cases of rickets, with especial reference to the following points:—The age of the parents, their health (particularly as regards the presence, in either of them, of any exhausting disease—e.g., phthisis), and such evidence of their having themselves suffered from rickets in infancy as might be furnished by the existence of thoracic deformity. The number and health of previous children, if any, were recorded. The circumstances of the mother during her pregnancy were inquired into. Next the hygienic surroundings of the patient, especially as regards exposure to damp and seclusion from sunlight. Also the existence of other disease, antecedent or concomitant, more particularly inherited syphilis. Lastly, the nature and quantity of food administered since birth. The investigation in every case was conducted with some care. A good many of the records have unfortunately been lost, though the results of the inquiry remain. But I have succeeded in recovering those of the first eighty cases; which I have analysed afresh, in order to give numerical precision to my statements. Without going into needless details, I may briefly say that no constant relation was made out between any of the above reputed factors and the development of rickets, with one exception, diet. Take, for instance, the place of the patient in the family series, on which considerable stress was laid, many years ago, by Sir William Jenner. Among my cases of rickets 19 per cent. were first-born children, 13·5 per cent. were second-born children, 19 per cent. were third-born children, 13·5 per cent. were fifth-born children, 8 per cent. were sixth-born children, 16 per cent. were seventh-born children, 2 per cent. were ninth-born children and upwards. The larger proportion of the above cases can hardly be ascribed to the influence of repeated pregnancies in exhausting the mother's health, or reducing the standard of material comfort enjoyed by the parents. Again, as to inherited syphilis, only 13·5 per cent. of my cases are noted as unquestionably syphilitic, 12 per cent. more are marked doubtful. It is, perhaps, worthy of mention that of the 23 per cent. of the whole number in whom crania-tabes was observed no less than 75 per cent. were syphilitic. This, of course, adds nothing to the weighty evidence adduced by Drs. Barlow and Lees; I allude to it in passing, because, at the time my observations were made, I had no suspicion of there being any relation between the two things. These instances are enough to illustrate the kind of negative results brought out by the inquiry. The only positive result, as I have remarked, concerned the diet of the infant. It was found that no less than 92 per cent. of the whole number had been given farinaceous food of one kind or another before the age of twelve months. Here are the figures: 42 per cent. had had farinaceous food daily from their birth, 30 per cent. had had farinaceous food daily from the age of three months, 4 per cent. had had farinaceous food daily from the age of six months, 16 per cent. had had farinaceous food daily from the age of nine months. It may be added that in many, though not by any means in all, the first onset of the disease, and its degree of severity appeared to be distinctly related to the period at which the administration of starchy matter was begun, and to the proportion between this element of the dietary and the others with which it was invariably associated. Of the 8 per cent. of cases in which no starchy food had been given before the age of one year¹ several might have been ascribed to materna

¹ It must be remembered that the fact rests on the unsupported testimony of the mothers. My strong dislike to starch-feeding was well known among the out-patients of the Evelina Hospital, and their tendency would have been to conceal or to minimise it.

feebleness, the mothers suffering, at the time, from general arthritis deformans. One child was undoubtedly syphilitic, another was bred in a cellar, to which no daylight ever penetrated, and in which gas was continually burning. In one case only could no cause be made out. The first child of young and healthy parents, living amid excellent surroundings, free from syphilitic taint, nourished exclusively at the breast, began to show signs of rickets at the age of five months. The disease was mild, but unmistakable. So far, then, the result of the inquiry seemed to point decidedly in one direction. But clinical evidence of this sort, even when drawn from a very large number of cases, affords, at best, only a certain probability; sufficient, perhaps, as a provisional guide to action; but never amounting to proof. To obtain this, a series of experiments was undertaken with puppies, kittens, rabbits, guinea-pigs, and white mice. As soon as possible after their birth they were put upon a diet of pure arrow-root jelly, with a variable quantity of added milk. Their digestive juices were speedily found to be deficient in, or destitute of, amylolytic power: the starch-jelly passing through their intestines unchanged. Let me say at once that in the issue of these experiments I was disappointed. They were fairly numerous; but in no single instance were such changes produced in the osseous system as could be considered identical with those observed in the human subject. The administration of starchy food to these young animals was always followed by the usual phenomena of inanition; when the proportion of starch was great, they died quickly; when it was smaller, death was delayed for a longer period. But, quick or slow, the course of events was the same in all. The bones partook of the general atrophy; they were thinner and more frail than in healthy animals of the same age; but they never showed any specific changes at their junction with cartilage. I attributed my failure at the time, and I think justly, to the extreme difficulty I encountered in keeping the animals alive for any length of time. In no case did they live long enough to furnish me with evidence against the starch hypothesis, as they yielded none to confirm it. I believe, a French observer, M. Tripier, failed, like myself, to induce rickets artificially in the lower animals; with the details of his work I am unacquainted, as I have never succeeded in laying hands on a copy of his memoir. It was not without some feeling of surprise that I found myself baffled by an obstacle much more serious than I had been led to anticipate from the records of success achieved by earlier experimenters. Published statements had prepared me to find spontaneous rickets not uncommon among domestic mammals, and artificial rickets easy of production. Now I am bound to own that I have never been fortunate enough to see a case of true rickets in one of the lower animals, either during life or after death. I would not be understood to question the occurrence, or even the frequency, of the disease among them; but of this I am quite sure, that many instances of so-called rickets in the lower animals are instances of a disease of the skeleton by no means identical with human rickets; while with regard to many other cases that have been placed on record, the published evidence is sufficient to enable us either to affirm or deny their identity with the infantile disease. Experiment, then, did nothing to strengthen or to weaken the result of clinical observation. We may naturally ask, if the starch-hypothesis be admitted as probable, whether any possible connexion can be suggested between two sets of phenomena, superficially so disparate, as starch-feeding and rickets? In the first place, starch may be supposed to exert some directly noxious action by undergoing decomposition in the bowel, and yielding products capable of being absorbed into the blood, and exerting an influence on the development of the bones analogous to that exerted by phosphorus in Wagner's experiments. The objection to this is that, so far as we know, starch undergoes no such decomposition; we find it in the excreta, stained with bile, but otherwise unaltered. Secondly, it has been thought indirectly harmful, owing to its lack of nutrient properties. That the digestive organs of infants and young animals are incapable of converting starch into sugar has been proved both by physiological experiment and clinical observation. Were an infant fed on starch alone it would die of starvation. It would present the same symptoms and post-mortem appearances as the diseases of which I have already spoken. But such symptoms are not present in most cases of rickets. On referring to my list I find that 54 per cent. of my cases are stated to have been well nourished, 14 per cent. not

wasted, and only 30 per cent. ill-nourished. It must be borne in mind that the proportion of starch to the really nutrient elements of the dietary is seldom very great. Thus in 60 per cent. of my cases the children were suckled up to the age of nine months; in 27 per cent. for periods varying from one to six months; while only 13 per cent. of the whole number never had the breast at all. These were usually supplied with an abundance of cow's milk. In those very rare instances in which milk is altogether withheld, the child develops well-marked scurvy in conjunction with rickets. Of this I have seen more than one example. Moreover, there is clinical evidence that an infant may suffer from prolonged ill-health, may grow pale and waste away, may be severely scourged by syphilis, and yet escape rickets. I have notes of such cases, and I find that, in every instance, the mother's milk was the only food given. Lastly, it is conceivable that starch may operate indirectly by interfering in some way with the assimilation of fatty matter. The possibility appears to meet all the facts of the case more completely than any other, and is strengthened by what we know of the remarkable curative effects of cod-liver oil. In conclusion, I shall briefly notice three objections often urged against the hypothesis that rickets is a consequence of the premature administration of starchy food. First, the occurrence of congenital rickets. Is an infant ever born with the disease? I agree with Dr. Fagge in thinking that no sufficient proof exists of the identity of so-called "fetal rickets" with the disease we are now considering. Secondly, the occasional development of rickets at puberty. This has been more than once asserted to occur, but I know of no decisive evidence on the point. Thirdly, the geographical distribution of the disease. We find an American surgeon² stating that "rickets is a disease so rarely met with in our country, that I have no experience which would entitle me to speak of it authoritatively from my own observation." We can hardly suppose that infant feeding in the United States is very different from infant feeding here. Is it possible that the author is alluding not so much to rickets as to those rachitic deformities of the limbs which call for surgical interference, and which must be ascribed less to the disease than to its improper management at an earlier period of its course? Should the three objections I have specified be found to rest on an assured foundation, any theory which connects rickets with the administration of starchy food—or indeed with any error of diet—must be given up. Those, however, who, like myself, are inclined to hold such a theory, at any rate provisionally, as according better with the facts hitherto observed than any other, may be excused if they hesitate to abandon it until driven to do so by the unanswerable logic of well-authenticated specimens brought before the Society.—Dr. FAGGE asked what proportion of non-rickety children attending the same hospital were under the same hygienic conditions.—Dr. CRISP asked how long the animals experimented on lived.—Dr. BAXTER replied that he was fully alive to the fallacy suggested by Dr. Fagge's question, and he had satisfied himself that it did not vitiate his statistics. The animals never survived longer than two months, and most of them died much sooner.

Dr. BARLOW brought forward a case of so-called Fœtal Rickets as a contribution to the question as to whether there is a true fetal rickets in any sense comparable with infantile rickets. For the fœtus from which these specimens were taken he was indebted to Dr. Herman. It was believed to be of full term, and was born dead. There was nothing in the family history which would throw light upon the case, with the exception that one previous child out of a large number had been born with turned feet. The proportions of the child were very remarkable. There was nothing special about the head and trunk, the neck was short and thick, the limbs were very stunted. The upper limbs placed close to the body did not extend further down than the umbilicus, and the lower limbs from the ilium to the heel only measured each five inches. The lungs were not expanded. No gross disease was found in the viscera. "The specimens to which I wish to call attention are the bones of the fœtus. To begin with the limb bones. The clavicle is natural. It is longer than either humerus or ulna. It will be remembered that the clavicle is a membrane formed bone. The scapula shows much thickening of bone where the cartilage joins it, so that there appear to be two thick lips, including the edge of the cartilage. The

² Markoe, Diseases of the Bones. New York. 1872.

humerus shows very large upper and lower epiphyses and a short stout shaft. On section the epiphyses are cartilaginous throughout. There is no irregularity in the line of ossification, and there is no massing up of pale bluish material such as is seen in a typical rickety long bone at the junction of shaft and epiphyses. The bone of the shaft is hard and compact on the surface and cancellous in the middle, and there is more indication of a medullary canal than is seen in full-term foetal long bones. At the outer side of the upper extremity there is a very slight extension of bone over the base of the great tuberosity. There is a manifestation of a tendency to cupping round the epiphysis, which is very marked in Mr. Shattock's specimens, to be presently exhibited. The radius is exceedingly oblique in its direction, and presents a striking sigmoid curve with the pronator tubercle in the centre. In the lower extremity the only points to which I will refer are: (1) the remarkable bend of the femur concave on the flexor aspect, (2) the absence of an ossific centre in the lower epiphysis; and (3) an invasion of fibrous tissue from the periosteum, spreading at the junction of the shaft and epiphysis. The sternum and costal cartilages show no ossification. The ribs present distinct nodosities; but instead of being at the junction of rib and cartilage, these nodosities definitely belong to the bone, and each consists of a bony cup which surrounds the end of the cartilage like a sheath. This cup, in fact, is quite similar to the rudimentary sheath pointed out in the humerus and scapula. There is a similar cup at the vertebral end of the rib. There is nothing special about the vertebrae. In the cranium the clivus is very steep, the foramen magnum small and funnel-shaped; and what is most noteworthy, there is complete ankylosis between the basi-occipital and the basi-sphenoid. This is one of the cases which would have been classed some time ago as foetal rickets; but there are essential differences alongside of some superficial similarities. First, it will be seen that, with regard to the long bones, the epiphyses generally are enlarged, at all events as compared with the shafts. In true rickets it is not the whole epiphysis, but the line of ossification which is swollen; but here it is the whole epiphysis. Second, there are signs of intrusion of fibrous tissue from the periosteum in between the shaft and the epiphysis, and also of the formation of a sheath-like prolongation around, and external to the base of the epiphysis. This is well shown in the nodosities of the ribs. Third, the shaft is singularly hard and compact, there is no trace of any fracture, and the bendings which occur are exaggerations of the normal bends. There is no thickening of periosteum or rarefaction of medullary parts of bone such as is described in rickets. Fourth, the stunted growth in length of the shafts, whilst the thickness is normal or perhaps excessive, is quite different from anything seen in rickets. Now, it might have been argued that in this child there had been at one period of intra-uterine life a rickety condition, which, having run its course, had left merely hardened bent bones. But a microscopic examination of the ends of the bone, I think, gives no support to this view. Some sections made for me by Mr. Boyd show that the cartilage in the greater part of the epiphysis is not materially altered, but along the line of ossification the cartilage cells are greatly enlarged, and the vertical row formation, which is so striking a feature in normal ossification, is here conspicuously imperfect. Thus, unlike true rickets, there is no proliferation of cartilage; indeed, the ossifying cartilage is very scanty in amount, and the primary bone areolæ do not present the characteristic organ-pipe arrangement. The subsequent development appears to depend mainly on the periosteum. Thus it happens that the growth of the shaft in length is arrested whilst it grows normally, if not, even to an exaggerated degree, in thickness. The in-growth of fibrous tissue between epiphysis and shaft, and the cup-like sheath at the base of the epiphysis, are developed from the periosteum. Several years ago specimens like this were investigated by Heinrich Müller and Urtel, and they pointed out how essentially different this lesion was from true rickets, and Urtel proposed for it the name of foetal chondritis. Two years ago Professor Eberth published a monograph on the subject, including some observations of his own on a deformed calf, which showed similar lesions. Professor Eberth shows that with some variations this condition of long bones is one of the characteristics of cretinism. The premature union of the basi-occipital and basi-sphenoid which was pointed out by Virchow as occurring in a cretin's skull which he examined, has been made too much of in the various

accounts of cretinism. Eberth shows that it is not constant in cretins. It occurs in this specimen, and has been found in others, but not always. But the peculiar arrest of growth in the length of the bones from defective proliferation and row formation of the embryonal cartilage is probably a constant feature. The disease—'achondroplasy' is the term suggested by M. Parrot—may be defined as a defective plastic power in the embryonal cartilage."

Mr. S. G. SHATTOCK related some cases of Osseous Lesions in the Fœtus. He noticed altogether nine cases; one of his own, five in the Museum of the Royal College of Surgeons, three in St. Bartholomew's. All these specimens exhibit shortening of the limbs, curvatures of the lower, and in most cases synostosis of the basi-occipital and post-sphenoid bones. And the specimens in which the soft parts still remain exhibit the facial characteristics of cretinism, depression of the root of the nose, flattening and upturning of its tip, thick rounded edge, &c. And these showed, also, a general accumulation of subcutaneous fat, such as is recorded of nearly all such cases. The histological appearances of sections of the femur of the most typical of these specimens showed the line of ossification to be irregular; the cartilage cells in front large, round or oval, and collected in groups, without a serial arrangement. Ossification had extended irregularly into the cartilage without the production of primary areolæ, and the proper alveolar formation had been effected by excavation of the calcified cartilage through means of the advancing medullary tissue. Both Eberth and Müller describe cretinism in the calf, and there is a foetal bitch puppy (No. 318, Teratological series, Mus. Coll. Surg.) which presents the characteristic cretinous habit. These specimens as a whole exhibit much that is in a general way like rickets—viz., the shortness of the long bones, the comparative enlargement of their growing ends, their deformities of curvature, and the thickening of the flat bones. The essential error of nutrition would appear to consist in an histological spoiling of the cartilage concerned in the ossification-process which fails to furnish a medium for bone-formation. And the histological accounts of such cases contain evidence of analogy between this condition and that of rickets, not a progressing rickets, for in all these cases the osseous substance has been found firm, but a sufficient analogy to render it probable that some such cases represent recoveries from rickets which has both arisen and passed away *in utero*. However, there are very few cases on record in which the bones of the fœtus have been observed unnaturally soft, and in some of these (to judge from the multitudinous fractures recorded of them) it is less probable that the condition was one of rickets than one of those, as yet, obscure forms of disease which render the bones fragile rather than flexible.

Dr. LONGHURST regarded the disease as due to imperfect nutrition, a consequence of civilisation and its attendant evils. He did not regard the disease as syphilitic. It is certain that all syphilitic children are not rickety. For twenty years of his life he had been engaged in treating the children of syphilitic parents, many of whom were syphilitic, but they were not rickety, because they were not subject to its causes, being well fed, well clothed, under good sanitary conditions, and enjoying frequent changes of climate. Tubercle and rickets may coexist, but a markedly tubercular child seldom, if ever, becomes rickety. The chemical change in the bones was a marked feature of the disease, and pointed to its being a malnutrition rather than a diathesis. He agreed with Dr. Crisp in thinking much light might be thrown upon the subject by considering the disease in other portions of the animal kingdom. Though the disease is seen in the native children in the city populations in Africa and India, it is not seen in the country districts.

Mr. SPENCER WATSON, after careful investigation, was convinced that rickets was not a form of congenital syphilis. He thought that much might be learnt by a careful study of the geographical distribution of the disease, and quoted the opinion of Dr. Chevers and others to show its rarity in India, and in districts where five members of a family were often suckled together, and whether a case had been seen of a girl seventeen years of age still unweaned. He suggested that the inquiry would be a fitting one for a committee of the Society.

Dr. GOODHART was of opinion that in some cases of rickets there was actual enlargement of the spleen. He had seen it in four cases after death, and the cases in which it was present might by their pallid look be easily picked out

from others without any examination of the belly. The change, he had found, was best described as chronic congestion; the organ was large, and tough, capsule thickened, the pulp homogeneous, with excess of hyaline fibroid material in the stroma. This, when exaggerated and viewed in their sections, would give the glue-like appearance spoken of by Sir W. Jenner. He had only noticed the enlargement of the spleen in even possible association with rickets thirty-seven times; it was therefore infrequent, and he thought, with Drs. Gee and Dickinson, that it was not an integral part of the disease, but due to some antecedent change. He was surprised the state of the blood had not been referred to; it was certainly most abnormal. The red corpuscles are in three or four sizes; there is much granular material, and where the spleen is enlarged there is some amount of leucocytosis. He should call the disease a blood condition, and the question arose why the cartilage of all tissues should take on such a generated growth, probably because it was independent of highly elaborated blood elements. He could see no *à priori* reason why rickets should not exist in the fetus. While rickets was a perverted or arrested development, osteo-malacia is a disintegration of a fully-formed tissue.

Dr. FAGGE expressed his thanks to the various speakers, who had added so much interest to the discussion, which would no doubt be of great use in stimulating research. He had been told that he had misrepresented M. Parrot, but though he had been unable to find the expression he quoted in his published speech, he was of opinion that he had heard him make use of it. He thought it would be well to get rid of the word diathesis, as no two people mean the same when they use the word. For instance, would Sir W. Jenner allow with the President that scorbutus was a diathesis? And would the President agree with Sir W. Jenner in calling inherited syphilis a diathesis? He was extremely sorry if he had not done justice to Sir W. Jenner's lectures on rickets; they were the starting-point of all that is known in this country on the subject. He himself had first learnt what he knew from them, and had constantly referred to them in later years; and it was because he thought he knew the lectures too well that he attributed the observation of the tenderness of the muscles and bones to another source. He should be glad to say anything to induce anyone to read the lectures for himself.

THE PRESIDENT conveyed the thanks of the Society to Dr. Fagge and the other members who had kindly taken part in the discussion.

The meeting then adjourned.

Reviews and Notices of Books.

An Introduction to the Study of Fishes. By ALBERT C. L. G. GÜNTHER, M.A., M.D., Ph.D., F.R.S., Keeper of the Zoological Department of the British Museum. Pp. 720. Edinburgh: Adam and Charles Black. 1880.

THE number of original works in English on Ichthyology is remarkably limited. When we have mentioned Owen's article in his "Comparative Anatomy and Physiology of Vertebrates," Rymer Jones's article in the "Cyclopædia of Anatomy and Physiology," and that of Sir J. Richardson in the eighth edition of the "Encyclopædia Britannica," we have almost given all the works to which the student could be referred for a good general account of the structure and classification of fishes. We are glad, therefore, to welcome Dr. Günther's work as an important and much-needed addition to this department of our knowledge, written by one who is well known to have devoted many years of his life to the study of this branch of natural history, and to have had at his disposal the unrivalled stores of the British Museum. The work is divided into two parts, the first dealing with the history and literature, the anatomy and physiology, the growth and variation of fishes, and their distribution, both geologically, and in existing seas, rivers, and

lakes; the second part deals with their classification and zoological characters. The first part gives in full detail the characters of the various organs; the skeleton, muscles, nerves, organs of sense, of nutrition, respiration, circulation, &c., being treated in successive chapters.

Dr. Günther supplies a useful table of the synonyms of the bones of the head given by different authors, and we notice that he does not follow in all cases the newer lights of Huxley and Parker, but retains the names conferred upon them by Owen. We need hardly say that the anatomical part is described in such fashion as to leave little to be desired, though we should have been glad of a little more detail in regard to the nervous system, which is rather curtly given, and might with advantage have been more fully illustrated. An entirely new branch of Ichthyology is opened up in the section on "The Fishes of the Deep Sea." It was long thought that the abysses of the ocean must be entirely destitute of life, partly from the total absence of light and partly from the enormous pressure which must be sustained by any animal living at depths of ten or fifteen thousand feet or more, the pressure amounting to one ton per square inch for every 1000 fathoms. The dispersion of this error is one of the important results of the observations made by the naturalists on board H.M.S. *Challenger*.

Many fish were dredged in this expedition from great depths, and the animals thus obtained present many peculiarities. Their connective tissue is so weak as to break down under the slightest pressure. The osseous and muscular systems are very feebly developed. The bones possess a fibrous, fissured, and cavernous texture; and are light, with scarcely any calcareous matter, so that the point of a needle will readily penetrate them without breaking. The ligaments connecting the bones and vertebræ break with great facility. The muscles are thin and easily torn. They are all carnivorous. The lateral line is widened, and the muciferous system is greatly developed. The colours are simple. The eyes, which in fish living habitually between 80 and 200 fathoms, are large, become smaller, or are altogether lost, beyond the latter depth, and the defect of vision is compensated for by tentacular organs of touch, or by phosphorescent organs, the anatomical characters of which are very remarkable. Fish from the greatest depth are destitute of eyes. The *Bathypophis ferox* was obtained from a dredging in which the dredge descended 2750 fathoms, and is believed to be the deepest sea fish known. A long list is given of deep-sea fishes, though, doubtless, some may have been caught by the dredge in its ascent. In regard to the distribution of fishes in time, Dr. Günther expresses no opinion as to the nature of the minute, slender, pointed, horny bodies, bent like a hook, and with sharp opposite margins, which have been found in deposits belonging to the Lower Silurian and Devonian systems, and have been described under the name of *Conodonts*. By some these have been held to be the teeth of extinct fishes, whilst others have suggested they are the remains of annelids and molluscs. He considers the first undeniable evidence of a fish or indeed of a vertebrate animal occurs in the Upper Silurian rocks, in a bone-bed of the Downton sandstone, near Ludlow. It consists of compressed, slightly curved, ribbed spines, of less than two inches in length (*onchus*); of small shagreen scales (*thelodus*), the fragment of a jaw-like bar with pluricuspid teeth (*plectrodus*), the cephalic bucklers of what seems to be a species of pteraspis, and finally coprolitic bodies of phosphate and carbonate of lime, including recognisable remains of the molluscs and crinoids inhabiting the same waters. But no vertebra or other part of the skeleton has been found. The fish was probably a plagiostome. The fish remains of the old red sandstone, or Devonian series, can be determined with greater certainty. They consist of spines named

ichthyodorulites, belonging to chondropterygians and the remains of various ganoid fishes, with others belonging to the placodermi. Devonian fishes are frequently found enclosed in "nodules." These are elliptical flattened pebbles which have resisted the action of water in consequence of their greater hardness, and this greater hardness is due to the dispersion in their substance of the fat of the animal which decomposed in them. The flags of Caithness, which belong to the Devonian era, and which contain an abundance of these fossil remains, emit a peculiar smell when freshly broken. In the Carboniferous system the chondropterygians and ganoids have numerous representatives. The fishes of the Permian group resemble those of the carboniferous. The chief forms of the Trias are shark-like fishes, cestracions and ganoids. Ceratodus appears for the first time. The Lias is very rich in piscine remains, one hundred and fifty-two species having been described. Sharks, rays, and sturgeons make their first appearance, and the homocercal termination of the vertebral column begins to supersede the heterocercal. The Cretaceous group presents clear evidence of the further advance towards the existing fauna; whilst in the tertiary epoch the teleostians have almost entirely superseded the ganoids. A few families, like the freshwater salmonidæ, seem to have put in their appearance in post-pliocene times.

The Geographical Distribution of Fishes is treated of at great length by Dr. Günther. He divides them primarily into freshwater and marine, which, however, run into one another in such a way as to render the distinction very vague. Thus in every large river truly marine forms may be found ascending for hundreds of miles, not periodically, but sporadically, evidently the commencement of a change of habit, which ultimately converts the marine into a freshwater fish. So, again, geological changes may occur so slowly as to give time for accommodation to new conditions. A remarkable instance of this is seen in the case of the Baltic, which, by the gradual elevation of Scandinavia, has become separated from the Arctic Ocean, and by the excess of supply of freshwater over evaporation, has become almost fresh in its northern part, and yet nine species belonging to the Arctic Ocean have survived the change.

The second part of Dr. Günther's work is the systematic and descriptive part, in which the Families of Fishes are shortly diagnosed, and some account given of the species which, by their structural peculiarities, or by their usefulness to man, possess special interest. Typical examples of nearly all the families are illustrated by means of excellent woodcuts, and short notes are appended of any remarkable features in their life history. Interesting particulars are given, for example, in regard to the pilot fish, stickleback, cod, flying fish, salmon, and others.

In regard to the salmon, the points which may interest many of our readers who are lovers of the gentle craft may be here summarised. In the first place, no fossils of the freshwater forms of the salmonidæ are known; but fossils of the marine forms have been found in the chalk of Lewes. Their life history presents many points of difficulty, and the species are not as yet satisfactorily determined. Some of the species interbreed, and the hybrids intermix again with one of the parent species, thus producing much confusion to the taxonomist. The coloration again is subject to variation, and cannot be relied upon for purposes of classification. The young, however, of all the species are barred. The moulting of the scales coincides in the migratory species with their sojourn in the sea. The size may vary to an extraordinary extent with food and other conditions. Thus *Salmo fario* in a small mountain pool may never exceed eight ounces in weight, but in a large lake or river may run to sixteen pounds. Again, the proportions of the various parts of the body to one another varies exceedingly in one

and the same species. The salmon offers a most remarkable instance of irregularity as regards the age at which the individuals arrive at maturity. The male parr, which Dr. Günther entertains no doubt is the young of the salmon, may become sexually mature when only seven or eight inches long. Salmon in the grilse state make their appearance every year at the mouth of the Thames, ready to reascend and to restock this river as soon as its poisoned water shall be sufficiently purified to allow them a passage. Let us hope that this good time may soon come.

Professor Günther's book contains much that will interest readers of every class, and has been got up in a manner worthy of Messrs. Black.

OVARIAN DYSMENORRHOEA, WITH RETRO-FLEXION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—In the "Mirror" of hospital practice, THE LANCET, Dec. 4th, a case is related with the above heading as having been under the care of Dr. Herman at the London Hospital. As "Wynn Williams's" stem and shield is prominently referred to in the history of the case, I hope I may be permitted to make a few remarks thereon. From the history of the case, in addition to the "tenderness on pressure over the ovaries," "much pain was caused by pressure on the body of the uterus," and "per rectum there was greater tenderness on each side of the uterus, the most being on the left side." The patient also suffered from leucorrhœa and much pruritus of the vulva, and too frequent micturition. She was treated as an out-patient between five and six months. "There was no improvement in the symptoms, which, if altered at all, got rather worse. On May 18th, 1878, admitted into the hospital, and on May 30th "Wynn Williams's" intra-uterine stem and shield was put in.

No record of any other previous treatment is given whilst in the hospital—whether or not the uterus was depleted by leeches or otherwise, &c., to allay the pain and tenderness, so as to remove the subacute metritis and ovaritis, from which the patient was evidently suffering. Many of your readers have, in all probability, expressed their astonishment that metritis, perimetritis, and pelvic abscess did not result after the introduction of an intra-uterine stem under such conditions.

Whenever there exists symptoms of acute or chronic metritis, ovaritis, &c., it is essential first of all to subdue these before having recourse to the use of an intra-uterine stem. One word in conclusion, "Wynn Williams's" stem and shield was constructed more especially for the treatment of antelexions. I do not mean to say that I have never used them in other conditions of the uterus, but I have always adapted the shield according to the nature of the flexion; in fact, to introduce the stem and shield in a case of retroflexion the shield would have to be worn upside down, as antelexion is the exact reverse of retroflexion.

Query, may not the fact of the patient having become pregnant be due to the wearing of the stem, which I have frequently found to straighten the canal of the uterus without entirely removing the exterior effects of the flexion?

Yours, &c.,
A. WYNN WILLIAMS.

Dec. 18th, 1880.

A CENTENARIAN.—The following is extracted from the *Ormskirk Advertiser*, but we have received private authentication of the truth of the statement of age:—On Monday morning last Mrs. Hannah Heaton, who had reached the advanced age of 101 years, died at the house of her daughter, Mrs. Huyton, Pygon's-hill, Lydiate, where she had resided for some time. Although she had attained such a great age, Mrs. Heaton retained her mental faculties to the last, and was able to hold conversation with her neighbours and friends on current topics to an astonishing degree, her memory being marvellous. Up to a week ago she was able to take a walk, sometimes extending half a mile, without help.

THE LANCET.

LONDON: SATURDAY, DECEMBER 25, 1880.

Introduction.

THE year 1880 has been historical indeed in the political sense. It has been so much so, and so disturbing, as to make professional and scientific men thankful for arenas of quiet unsensational work and employment in which progress is more regular and unagitated. We may notice two or three facts of almost physiological interest in connexion with great historical events in the year. On the retirement of one Premier another was called to take his place, full of physical and mental vigour, though over seventy years of age, who, after the labours of an arduous session, was able, under the guidance of Dr. Andrew Clark and Sir William Jenner, to pass successfully through a sharp pyrexial attack. The other event of as much physiological and historical interest was the march in three weeks of our troops under the able lead of General ROBERTS from Cabul to Candahar, with the loss of only two Europeans, seven sepoy, and twenty-one camp followers. Such a march was not achieved without medical anxiety, and it is not without significance recorded that the medical officers of the expedition were never absent from their posts for one hour. Though the mortality was slight, we shall probably hear more cases of sickness. The distress of Ireland has not been without such alleviation as comes from better administration and more efficient medical aid; and the disastrous fevers of former years of famine have not been repeated on any large scale.

Anatomy and Physiology.

In Anatomy and Physiology, and the allied subjects of Histology and Physiological Chemistry, several important treatises have been published, and, as usual, a very large number of separate papers or memoirs. Foremost amongst the larger works are the volumes of Dr. L. HERMANN'S "Handbuch der Physiologie," dealing with the blood and circulation, and with the physiology of secretion and digestion. This cyclopædia, to those who have mastered German, affords the best and most complete *résumé* of the science of physiology extant; though it does not constitute so marked an advance on previous knowledge as was the case with the old "Handwörterbuch der Physiologie" by WEBER, published between the years 1842 and 1853. It has the advantage, however, of being brought out more rapidly, and thus better representing the actual state of the science. Next to this is the Physiological Chemistry of Prof. GAMGEE, which well sustains the repute and scientific position of its author. It is to be succeeded by a second volume, in which the secretions will be specially considered. A smaller treatise by WURTZ, entitled "Traité de Chimie Biologique," may also be advantageously consulted. One of the best physiological textbooks, if not the best we have seen, is that just issued by LANDOIS, a translation of which would be a boon to the English reader, and we trust will be undertaken by some industrious student. New editions of the Manuals or Text-

books on Physiology by Dr. KIRKES, under the editorship of Mr. MORRANT BAKER, by Dr. FOSTER, and by Dr. CARPENTER, under the editorship of Mr. POWER, in English, and of those of BEAUNIS, BÉCLARD, FUNKE, and RANKE have appeared, as well as of WUNDT'S "Grundzüge der Physiologischen Psychologie." MILNE EDWARDS has brought his splendid work, "Leçons sur la Physiologie et l'Anatomie Comparée," to a close in the fourteenth volume. It is a model of the French style of exposition, though the arrangement adopted is rather unusual. There is a text clear, condensed, luminous; then on the same page notes, giving in detail many of the points only alluded to in the text; finally, and still on the same page, is the bibliography, which is extraordinarily copious and exact. HARTMANN of Berlin has added another to the numerous handbooks of Human Anatomy; the sections on the muscles and arteries are accompanied by rather coarsely coloured but distinct woodcuts. Under the title of "Anatomische Varietäten," KRAUSE has issued an appendix to his large work, the "Handbuch der Menschlichen Anatomie," which will be found useful to all teachers of anatomy, and indeed to all operating surgeons, since it gives details with regard to topographical anatomy and in regard to weight and measurement not elsewhere obtainable. A good German translation of QUAIN'S "Anatomy," containing much additional matter, is in course of publication by SCHWALBE.

The art of Histology has been advanced by the publication of the "Leçons sur le Système Musculaire" of M. RANVIER, though it is not clear why, if he had time to finish this treatise, he could not complete his half-published "Leçons d'Anatomie Générale," which seems to have stopped at the fifth part, to the great inconvenience of purchasers of the earlier parts. The more important contribution to this branch of physiological technic, however, is the handsome Atlas of Histology, just completed by KLEIN and NOBLE SMITH, the numerous drawings in which are for the most part original, and very faithful renderings of the objects they represent.

Though not exactly belonging to either Anatomy or Physiology, yet, as constituting very valuable and interesting additions to Biological science, two works must be mentioned: first, Mr. DARWIN'S "Movements of Plants," which, like all the volumes he has written, presents in short compass the results of an immense series of observations in this instance on a subject of surpassing interest; the other is the magnificent volume which constitutes the first instalment of the scientific results of the exploring voyage of H.M.S. *Challenger*, and which contains valuable papers by DAVIDSON on the Brachiopoda, by KÖLLIKER on the Pennatulida, by GÜNTHER on the Shore Fishes, by PARKER on the Development of the Turtle, as well as others, proving indisputably the existence of a large fauna in the abysses of the ocean hitherto held to be void and tenantless. The Ray Society have issued two well-illustrated volumes of BRADY'S "British Copepoda." A new journal, the *Archives de Biologie*, has appeared in Belgium, under the able superintendence of ED. V. BENEDEN and of CHARLES V. BAMBEKE, and the four parts that have been published contain some good articles, especially two by V. BENEDEN himself on Development. The *Journal of Anatomy*, under Professor HUMPHRY'S guidance, has been punctually issued,

and contains some excellent papers, amongst which we may particularly notice one by Dr. CREIGHTON on Bovine Tuberculosis in Man, and one by Dr. BEATSON on the disease called "Sturdy" in sheep.

Amidst the multitude of Memoirs on Physiology, it is here only possible to select a few that may be regarded as presenting special features, and even of these little more than the headings can be given. Taking the subject of Digestion, to begin with, it may be observed that WURTZ has investigated the peculiar properties of the juice obtained by incisions made into the green fruit of *Carica papaya*, which possesses a digestive property, and is capable of dissolving and peptonising albumen. The active principle is papain, which seems to be analogous to trypsin — the albumen-digesting ferment of the pancreas; and it may hereafter be usefully employed therapeutically as a digesting agent. Various observers have paid particular attention to the formation of peptones. SCHMIDT-MUELHEIM has been led from his experiments to accept as peptones only those substances which give no cloud with acetic acid and ferrocyanide of potassium, and believes he has determined the existence of a stable product intermediate between albumen and peptone, to which he has applied the term propeptone. His attempts to determine the paths by which peptones are absorbed from the intestinal canal demonstrate that the blood of a fasting dog contains no peptone, though it is present in the blood of an animal that has been fed twenty-four hours previous. On the other hand, none was then contained in the chyle, though this was milk-white. Experiments in which solutions of peptone were injected into the vessels showed that this substance rapidly disappeared, so that whilst one minute after the injection nearly the whole quantity injected could be recognised, after six minutes it was reduced to a trace, and after ten minutes had entirely disappeared. The peptone injected so changed the quality of the blood that it no longer coagulated on withdrawal from the vessels; the addition of a little fibrin ferment, however, immediately caused coagulation to take place. An important fact in view of the therapeutic injection of peptone which has been recommended was made out — namely, that the injection of this substance lowers the blood-pressure to an extraordinary extent, the pressure of the blood in the carotid artery of a dog falling from 208 mm. to 12 mm., and death rapidly ensuing. ALBERTONI, in following up this inquiry, made the observation that considerable differences occur in different animals, the injection of peptone into the vessels of dogs preventing the coagulation of their blood, though it is ineffective in rabbits and in sheep. The action of the peptones in dogs seems to be essentially on the white corpuscles. His experiments show further that the peptones when injected into the vessels rapidly disappear from the blood, and enter the tissues and organs of the body. Some good lectures on the Physiology of Digestion were delivered by EWALD, and have been collected into a small handy volume, which practitioners may consult with advantage as giving all recent work on the subject.

MAYDL has investigated the point whether the glycogen obtained from the liver and from the muscles in animals fed on meat and potatoes, on glycerin, on inulin, and on starch, was in all instances identical in composition, and produced the

same amount of sugar as tested by polarisation experiments. He satisfied himself that it was identical, and hence argues that glycogen cannot result from a direct conversion of these several substances into glycogen, but that this must be a special product of the functional activity of these tissues. Hæmoglobin crystals may, according to WEDL, be obtained in the course of from twenty-four to forty-eight hours, even from those kinds of blood which do not readily crystallise by the addition of a little strong pyrogallie acid. BÖGYES has examined the hæmin crystals obtained from the blood of a large number of mammals and birds, and finds that in all instances the form is essentially similar, and that they do not, as usually stated, belong to the rhombic, but to the monoklinic or to the triklinic system. The place of development of the red blood-corpuscles in birds rendered anæmic by bleeding has been investigated by BIZZOZERO and TORRE. The birds experimented on were the cock, pigeon, crow, finch, wild goose, swallow, and sparrow, and they adduce strong evidence to prove that the new red corpuscles are developed in the red marrow of the bones. Similar results have been obtained by OBRASTZOW, who describes in considerable detail the transitional forms between hæmatoblasts or nucleated red cells and true red corpuscles. The same results have been arrived at by RINDFLEISCH, who states that the veins and capillaries of the red marrow possess no proper wall, whilst that of the arteries is extremely delicate. MOENS discusses the formation of the first wave in the descending limb of a sphygmographic tracing. He divides the contraction of the ventricles into three periods, the first lasting 0.085 of a second from the commencement of the contraction to the opening of the semilunar valves; the second lasting 0.1 sec. which represents the period of complete patency of the semilunar valves, and the third lasting 0.115 sec., which extends to the moment when the valves close. The movement of the blood attains its greatest velocity towards the close of the second period. The recoil of the vessels which closes the semilunar valves occasions a small secondary wave, which is propagated from the valves outwards, and appears as the first wave in the descending limb. ROY and BROWN contribute a paper on Blood-pressure and its variations in the arterioles, capillaries, and smaller veins to the *Journal of Physiology*, a journal that is excellently conducted by MICHAEL FOSTER of Cambridge, but which, we fear, is scarcely supported sufficiently by the profession to prevent its editor and his colleagues, with the publishers, suffering large pecuniary losses with each number. Messrs. ROY and BROWN find that the capillary vessels possess contractility rather than elasticity, and that these are capable of undergoing individual variations of calibre, and they believe that such variations stand in relation with the requirements of the tissue. A very long and elaborate memoir on the Time Relations of the Excitatory Process in the Ventricle of the Heart, also by Professor BURDON-SANDERSON and F. J. M. PAGE, appears in the *Journal of Physiology*. They show that the rate of propagation of the excitatory state is about five inches per second, and the duration of this state is in winter frogs from 1.6 to 1.8 inches at a temp. of 12° C. Each part of the surface of the ventricle is, during the excitatory state, negative to every unexcited portion. The local application of heat shortens the duration of the excitatory state; injury weakens or diminishes the excitatory state.

CHRISTIANI believes he has established the existence of a respiratory centre in the floor of the third ventricle, which can be excited to activity through the optic and auditory nerves when stimulated. This centre induces arrest of respiratory movement in the condition of full inspiration. OSCAR LANGENDORFF adduces various facts which he interprets in favour of the existence of one or more respiratory centres in the spinal cord. KRONECKER and MARCKWALD have shown that the ordinary respiratory contraction of the diaphragm is to be regarded as a brief tetanus, since in order to produce the regular and ordinary curve of inspiration twenty excitations per second must be applied to the phrenic nerves. A discussion upon the normal curve of respiratory pressure has been carried on in Pflüger's *Archiv* between EWALD and GAD, in which the numerous points demanding attention in a proceeding apparently so simple are well brought out. The influence of mixed and monochromatic light on the excretion of carbonic acid by animals has been studied by MOLESCHOTT and FURBINI. They support the statement now generally accepted, that white light, both by its action on the eyes and on the skin, increases the excretion of carbonic acid gas. In regard to monochromatic light, the excretion of carbonic acid is as free in violet as in white light; red light somewhat raises the amount in warm-blooded animals, but has no effect in the case of frogs. In opposition to the generally accepted doctrine, SPECK finds that cooling of the external skin exerts little or no influence upon the oxidation processes in the body. The first action of cold to the surface, as in the administration of an ordinary cold bath, is to cause constriction of the cutaneous capillary vessels, and thus to drive into the general circulation the blood contained in them. Then, since no blood traverses these vessels, there is no loss of heat in the blood, and the temperature temporarily rises. On emergence from the bath, however, the cutaneous capillaries relax, and then the blood, as it traverses therein, becomes cooled down, and on re-entering the general circulation reduces it below the normal. The different results obtained by different observers he attributes to variation in the deviation of the application of the cold, and of the spasm of the vessels. Some interesting observations upon the temperature of the head have been made by MARAGLIANO of Genoa, from which he concludes first, that the temperature outside the skull is a correct index and exponent of the temperature of the brain within, though this has since been disputed. Secondly, that the temperature of the left side of the head is always higher than that of the right. Thirdly, that the temperature of the frontal and temporal regions taken at the external orbital process and over the mastoid process, is always higher than the occipital region taken over the occipital protuberance; and lastly, that intellectual activity, age, and sex exert considerable influence over the temperature of the brain. The most important histological discovery in regard to the structure of the nerves is undoubtedly that which has quite recently been published by ENGELMANN, who is a reliable observer, to the effect that the axis cylinder, which has always hitherto been regarded as continuous and uninterrupted from one extremity of a nerve to another, is in reality discontinuous; in the frog at least it presents constrictions. DASIDA calls attention to a fact that has

hitherto been overlooked—namely, that the ganglion on the posterior roots of the spinal nerves, which is always stated to be single, is in reality in many instances double, or even in some instances treble. The statements of BROWN-SÉQUARD, so long taught in our schools, in regard to the paths of conduction of motor impulses and sensory impressions on the spinal cord, have of late years been frequently impugned. The latest experiments are those of WEISS, who has made numerous sections of the cord in dogs at the level of the last dorsal vertebra. He finds that immediately after division of one lateral half of the cord in this region there is complete loss of motion and sensibility on both sides below the section. A few days after the operation the motion of the leg of the uninjured side becomes perfectly restored, whilst the leg of the same side remains paralysed. The sensibility of both legs is lowered, and apparently to an equal degree. Hyperæsthesia was never present. In the course of three or four weeks the power of moving the leg of the side of the hemisection often undergoes remarkable improvement, whilst the sensibility remains unaltered. WEISS believes that each lateral column of the cord contains both sensory and motor fibres for the two sides of the body, the former being equally, the latter unequally, distributed. STRICKER and UNGER have examined the structure of the Brain in sections stained with potassium, gold-chloride, and then hardened in alcohol. This method seems adapted to bring into extraordinarily distinct relief the various forms of cells and their ramifications, and to establish a very intimate relation between the connective-tissue cells and the nerve cells.

The precise origins of the Cranial Nerves have been investigated and delineated by DUVAL, whose observations agree well with those of LOCKHART CLARKE. WOLF observed a case in which the function of the Chorda Tympani was clearly determined in consequence of its accidental division during the operation of division of the tympanum. The effects observed were as follows: loss of the sense of taste for sweet, salt, bitter, and acid flavours on the same side for the anterior two-thirds of an inch. There was also loss of sensibility for tactile and thermic impressions. It is remarkable that complete recovery of the sense of taste took place eight weeks after the section. BLAU had a case in which the chorda tympani was exposed; mechanical irritation of it excited an acid taste in the tongue on the corresponding side, and a trembling of the muscular fibres. Some recent experiments by BIGELOW on animals, though less precise, lead to the same conclusions. The quantity of Cholesterin contained in the Brain has been determined by BENEKE, and shown to reach the large amount of 2.12 to 2.34 per cent. of the fresh brain.

In Development, HIS has contributed some important observations on the genesis of the peripheric nervous system, and has published a large work in folio under the title of "Anatomic Menschlichen Embryonem." BALFOUR has collected his researches, extending over several years, into one volume of "Comparative Embryology," which contains a large number of original and very interesting researches. KLEIN has studied the development of the Spermatic Cells and Spermatozoa. Dr. MARTIN is doing good work in the Biological department of the Johns Hopkins University in America; and an excellent memoir

on the development of the Oyster, by Mr. BROOK, emanates from the same source.

Pathology.

In the department of Pathology the year has not been unproductive. The foremost place among the investigations must be given to the researches into the part played by minute organisms in the production of disease. Although no entirely new discovery has been made, the results obtained in previous years have been confirmed and extended. The most noteworthy investigations have been, as usual, those of M. PASTEUR, into the so-called cholera of fowls and the influence upon it of inoculation, but thanks to the Brown Institution, important researches in an allied field, by which the discoveries of PASTEUR have been in part anticipated, have been carried on by Dr. GREENFIELD, whose excellent lectures have been published in our columns. Mr. LISTER'S address at Cambridge and the discussion which followed, constituted an important means for the diffusion of knowledge on the subject. In Germany the life-history of bacteria and allied organisms has been carefully examined by KUHN and FOKKER, in relation to wounds by MAX WOLFF, and as a cause of disease of the lower animals by GRAWITZ and EBERTH; while the last named observer has also studied their relation to typhoid fever. Of investigations into problems of general pathology we may especially mention those on the subject of fatty embolism by WIENER, and the elaborate series of studies on amyloid degeneration which have been published by KYBER. The infective production of tuberculosis has been proved experimentally by TAPPEINER and BOLLINGER, and the theory has been boldly applied to the origin of tubercular disease in the human subject by COHNHEIM and CREIGHTON. The influence of the nervous system on nutrition formed a subject of discussion at the British Medical Association, and it elicited some interesting facts from HUTCHINSON and BROWN-SÉQUARD. The possibility of the regeneration of the spinal cord has been demonstrated by the experiments of EICHORST. Of the diseases of the spinal cord in man, some important contributions on the subject of myelitis have been made by LEYDEN, on lateral sclerosis by DEBOVE and GOMBAULT, and on the chemical composition of the bones in locomotor ataxy by REGNARD. Interesting investigations have also been made on the changes in the nervous system in certain skin diseases, especially in anæsthetic leprosy, by TSCHIRJEW; in herpes zoster, by CHANDELEUX; and in ichthyosis, by LEOIR. In pulmonary diseases we may note the remarkable discovery in Japan of a form of hæmoptysis of parasitic origin, by BÆLZ; the investigation into the changes in the lung epithelium in pneumonia, by VERAGATH; and the termination of pneumonia in induration, by MARCHAND. Renal disease has also been a fruitful subject of research. The pathology of granular kidney has been studied by ROSENSTEIN, SAUNDBY, and LEWINSKY, the associated arterial changes by SOTNITCHEWSKY, and that of glomerular nephritis by LEECH.

Therapeutics.

Our pages have borne testimony to the fact that while in a few there may be an overweening interest in Pathology, the great body of the profession is still devoted to the cultivation of Therapeutics. Proofs too of the practical power of

Medicines emerge even in the midst of pathological discussions. To take a recent illustration, Dr. DICKINSON in the recent debate on Rickets, speaking of the visceral disease incident to it, said, "It is amenable to treatment, though slowly, under cod-liver oil, iron"—we should have added quinine—"and hygienic measures; a spleen which touched the pelvis may gather itself up so as to be nearly out of reach of the fingers." Mr. TWEEDY published a series of cases of true diphtheritic ophthalmia successfully treated by local applications of quinine. It is idle to affect contempt for medicine when such statements can be made by the most careful observers.

Amongst the various subjects in practical Therapeutics which have engaged the attention of the profession has been the employment of intra-venous injections of milk. Mr. ARTHUR MELDON published three cases in our columns in addition to five others, in which the operation was of important use. The treatment of Ringworm with Carbolic Acid by Mr. ALDER SMITH, and with Salicylic Acid by Mr. COTTLE, was well expounded in our columns. The great question of the use of Salicylates in Acute Rheumatism was boldly raised by Dr. GREENHOW in the Clinical Society. His verdict was rather discouraging in tone, based on a considerable hospital experience. But even his admissions were to the effect that no other remedy has such power over the pyrexia and pains of rheumatism. His objections were to the toxic effects of these remedies, which, it is to be hoped, and which there is good reason to believe, will be found to be avertable or controllable. The enormous interest of the therapeutics of acute rheumatism is shown in our columns by a number and variety of communications, which we cannot attempt even to enumerate. One question which has come very much to the front in these discussions is the degree in which the heart structure is affected by acute rheumatism itself, apart from medicines having a depressing effect. Notwithstanding Dr. GREENHOW'S cases, the general opinion of the Society and of the profession is to the effect that these drugs are agents of great value and significance. The question of safe anæsthetics is still actively engaging attention, with an inclination in favour of ether as compared with chloroform, or a combination of the two. The treatment of puerperal fever has been fortunately the subject of discussion by Dr. MATTHEWS DUNCAN, whose lectures will be found in our columns. They give the weight of his great authority to the new method of treatment by antiseptic injections, ergot, quinine, iron, support, &c.; treatment which has long been used by many practitioners, but which has not been enunciated by authorities with quite sufficient distinctness. One great or rather slight ray of hope appeared in the course of the year in regard to a still more distressing disease—viz., cancer. Professor JOHN CLAY of Birmingham published in our columns a paper on the use of Chian turpentine in carcinoma uteri. As this subject is noticed in another part of our summary, we will not detain the reader with it here. The therapeutical use of Arsenic has been the subject of an interesting paper by Mr. MALCOLM MORRIS, delivered before the Medical Society of London. The disagreeable disease of bromidrosis is reported by Mr. WM. BRETT of New Cross, to have yielded to the local application of oleate of mercury. The delicate question of the use of alcohol in pneumonia has

been carefully touched by Dr. OCTAVIUS STURGES and by Surgeon JOHN HOYSTEAD, who had to treat the disease at Fort Dekka (four stations up the Khyber Line route to Cabul), and found alcohol helpful. Alcohol, as a general therapeutic agent, is being subjected everywhere to most suspicious treatment, by physicians and by boards of guardians alike. It has still friends who think it indispensable, either to preserve health or to cure disease, but the wisest physicians show themselves chary either of taking or recommending much of it. Dr. SYDNEY RINGER and Dr. WM. MURRELL have found glycerine curative of flatulence, acidity, and dyspepsia. This is a thing to be noted in an age when sugar is so critically regarded by physicians. A recovery from tetanus, treated by three pounds of chloroform, inhaled over about six days, was recorded in THE LANCET. Dr. HENRY KENNEDY reminds the profession of the use of rather large doses of extract of henbane in cancer. Not the least noticeable therapeutical communication of the year is that by Dr. RODERICK KENNEDY of Kingston, Canada, on the use of large doses of olive oil for softening and causing the easy expulsion of biliary calculi. Three cases were reported, in two of which 200 calculi followed the use of the oil.

Surgery.

In looking back over the past twelve months, it will be evident that there is no lack of zeal in the study of Surgery in both its scientific and practical aspects. In all directions we find able workers plodding on and gradually, though not continuously, advancing this branch of science and art. It has always been that special interest has centred round particular departments of Surgery, and we have accordingly to note discussion and invention following along the old familiar lines. The treatment of Wounds now, as ever, occupies a large share of the attention of surgeons, and while the past year has little or nothing of a novel character to add to our knowledge of this subject, and while surgeons are as little agreed as ever on the particular details to be observed or methods employed, they are more and more at one as to the great objects to be aimed at. It is no exaggeration to say that all surgeons now claim to practise Antiseptic Surgery, though the contest is as hot as ever over the best method of carrying out this endeavour. Listerism, which is becoming daily more widely known, is, however, in some danger of being prejudiced by the indiscretion of many of its disciples, whose zeal is not tempered by knowledge. How else can we speak of descriptions of wounds healing without suppuration *because* they were dressed with Lister's gauze under a spray of carbolic lotion? Such ignorance or folly must injure a system, and will neutralise the good effect of the adhesion to it of many wise men. Few things are more to be dreaded than that the notion should ever gain credence that Listerism or any other mode of dressing is a perfect and unfailing safeguard against all danger in operations and wounds, and that its use absolves the surgeon from the serious duty of weighing well the justification for his treatment, or from the exercise of appropriate skill in the performance of operations.

Side by side with, and as a necessary result of, the general practice of antiseptic surgery, Operative Surgery slowly ex-

tends its domain over regions hitherto considered beyond its pale. On the one hand, operations upon bones for the correction, especially of rickety deformities have become common—in the opinion of some of the older members of the profession too common. On the other hand, renal tumours and calculi have been successfully removed. Nephrotomy, the name by which the operation of cutting down upon the kidney from the loin is known, has been practised by BARKER, MAY, MORRIS, and PUZEY, whilst removal of the entire kidney—Nephrectomy—has been performed by SIMON, CZERNY, BARKER, THORNTON, and LUCAS. The feasibility of each of these operations is therefore established. Whether and when they are justifiable a larger experience is required to enable us to decide. A hope often kindled, and as often disappointed, has been again raised by Professor CLAY's statements in support of Chian turpentine as a very valuable palliative, even if not an actual cure, for cancerous growths, particularly of the female generative organs. The success which was stated to have followed the administration of the drug was so marked that more than ordinary interest was excited by the announcement first made in our columns. We have published many communications on the subject, and without judging a question which is still to be fairly considered under discussion, we are not unwarranted in expressing the fear that the bright hopes at first held out have not been realised; that nothing in the nature of a cure for cancer is to be found in Chian turpentine; that it has failed even to relieve many examples of undoubted cancer of the uterus; and that, at any rate, some of the cases which have been benefited by its use are open to the fatal objection that they were not cancerous in nature, an error easily explained when the difficulty of diagnosis in the early stage of cancer is borne in mind. In the surgery of the Genito-urinary Organs the year just closing has seen BIGELOW's operation for stone in the bladder more firmly established. Increased experience has proved the truth of the chief of BIGELOW's maxims, though most English surgeons have preferred not to follow their American *confrère* in his entire contention. The evidence now before the profession appears conclusive that lithotripsy with evacuation is far preferable to the older method of CIVIALE, although whether BIGELOW has extended the limits within which the crushing operation is advisable is at present uncertain, such an astute surgeon as CADGE being of opinion that he has not. Mr. CHEYNE has shown us that Gonorrhœa must be added to the list of septic inflammations, and has introduced a mode of treatment by antiseptic bougies specially directed against this feature; his recorded results are satisfactory. HARRISON has added yet another to the long list of means at our disposal for the Treatment of Gleet—Irrigation of the Urethra—and in suitable cases this treatment, properly carried out, is very serviceable. The Treatment of Stricture of the Urethra was one of the subjects specially discussed in the Surgical Section of the British Medical Association at its annual meeting at Cambridge, and it has formed the subject of several memoirs in France and America. Internal Urethrotomy would appear to be gaining in favour with most "specialists" in this department, but Dr. GRÉGORY of Bordeaux has published an able defence of the older operation of External Urethrotomy, and a serious indictment against its newer rival.

The space at our command forbids us to speak further of the progress made in the practice of Surgery during this year, or we might refer to BAKER'S method of excising the Tongue, POLLOCK'S operation for Piles, and many others. But even such a hurried survey as we have been able to take of the year's work, while not showing us any great discovery or acquisition which can be looked upon as a landmark, is yet sufficient to assure us that Surgery is being actively pursued both as a science and an art, and is steadily advancing along the path by which its value to mankind will be enhanced.

The Royal College of Physicians.

The Royal College of Physicians has not, as usual, supplied much material for history. In accordance with a custom of which we took an opportunity of disapproving, it has re-elected its President, Dr. BENNETT, for the fifth time. The College in this custom pays a poor compliment to its Fellows, by seeming to think that they include so few fit for the chair. That Dr. BENNETT has served the College well in no way detracts from the force of our objection to a bad custom. The College showed itself alive to the movements of current opinion in the matter of Examinations. In the early part of the year, at a meeting of the Fellows, a new set of bye-laws for the College licence was adopted. The Royal College of Physicians deserves the credit of being the first of the English corporations to institute a thorough system of examinations, for the Apothecaries' Hall does not examine in Surgery, and the College of Surgeons has only just begun to appreciate that Midwifery and Toxicology, not to mention Chemistry, Physics, and Botany, are subjects of importance to the general practitioner. We understand that the Council is considering the expediency of instituting examinations in these subjects, but at present they are not included in the examinations for either the Membership or the Fellowship. The examination for the licence of the College of Physicians is divided into three parts: the first comprising Chemistry and Chemical Physics, Materia Medica and Medical Botany, and Osteology; the second, Anatomy and Physiology; and the third, Medicine, Surgery, Midwifery, and Toxicology. Students who have passed in many of these subjects are exempted from re-examination, and the effect of such a liberal scheme has been most marked. At the last examination nearly fifty students were examined in the first series of subjects, and nearly thirty in the third series. As most English students pass in Anatomy and Physiology at the Primary Examination for the membership of the College of Surgeons, the numbers for the second part are necessarily always small, but even here we understand there was also a decided increase. The profession and the public should understand that the new examination for the licence is as practical and as thorough as most university examinations, and that the Licence of the Royal College of Physicians necessitates as complete an education as that which is enforced for most of our M.B. degrees. The Gullstonian Lectures were delivered by Dr. GOWERS, the subject being Epilepsy; the Lumleian, on the Digestive Ferments, by Dr. W. ROBERTS, of Manchester; and the Croonian, on Some Points in the Pathology and Treatment of Typhoid Fever, by Dr. W. CAYLEY.

The Royal College of Surgeons.

The Council of the Royal College of Surgeons of England has during the past year manifested unusual zeal in the cause of medical education. It has resolved to take steps, either alone or in conjunction with other bodies, to institute a complete examination to be passed by all candidates for the diploma of Member or Fellow, without waiting for the fulfilment of the Conjoint Scheme. It has also recently agreed to the principle of relegating the preliminary examination to the general educational and examining bodies. With a view to diminishing the number of rejections, and to obviate a pecuniary loss for re-examining rejected candidates, the Council has resolved that all candidates for re-examination shall pay a fee sufficient to cover the costs of examination. At the annual election of members of the Council last July there were four vacancies, caused by the death of Mr. HENRY HANCOCK, the retirement by rotation of Messrs. BUSK and CURLING, and the resignation of Mr. JOHN SIMON. Mr. CADGE, Mr. BRYANT, Mr. LISTER, and Mr. THOMAS SMITH were elected to the vacancies. In January Mr. HULKE was elected a member of the Court of Examiners in the place of Mr. CURLING; in March Mr. BELLAMY and Mr. MCCARTHY were appointed to succeed Mr. WOOD and Mr. HULKE as members of the Board of Examiners, and in April Mr. COOPER FORSTER was re-elected a member of the Court of Examiners. In July Mr. ERICHSEN was elected president, and the previous professors and lecturers of the College were re-elected, with the exception of Mr. LOWNE, who had resigned the Aris and Gale lectureship, and was succeeded by Mr. GERALD YEO. Mr. LE GROS CLARK having retired from the Court of Examiners, Mr. JONATHAN HUTCHINSON was appointed in his place in October. On the 9th inst., the Board of Examiners was appointed, all the previous members being re-elected, except Mr. HEATH and Mr. POWER, whose term of office had expired. Mr. LANGTON and Mr. GERALD YEO were appointed in their places.

Army and Navy Medical Departments.

The year has been one of comparative quiet in the Army Medical Department. In February the promotion of fifty surgeons-major to the rank of brigade-surgeon took place in accordance with the provisions of the Royal Warrant of November, 1879. At the two competitive examinations for admissions into the service there was an adequate supply of candidates, and, as we learn from Netley, of a very good stamp. This justifies the inference that the provisions of last year's Warrant have been deemed satisfactory by the profession. The successful manner in which the work of the Department has been done with the force in Afghanistan furnishes very strong evidence in favour of the present system of organisation, about which so many doubts were expressed at the period of its adoption. It is gratifying to find that Sir FREDERICK ROBERTS does not, like some other Generals, ignore the officers of the Medical Department, but has brought to the notice of the Government the zealous and efficient manner in which they have performed their arduous duties. At the close of the year a Royal Warrant was published regulating the medical department of the Household Brigade and removing certain grievances of which they had just grounds to complain. If it be considered necessary to

keep them distinct from the Army Medical Department, and to conduct the service of the Guards on a different principle, it is but just that when benefits are conferred on the other medical officers those of the Household Brigade should not be overlooked. But while the year has passed quietly for the Army Medical Department it has been very different with the Indian Medical Service. In the beginning of the year a General Order was published by the Indian Government abolishing the dual administrative medical staff, and giving to the army medical officers a large proportion of the remaining administrative appointments, without apparently granting any compensation to the Indian service for those of which they were deprived—a proceeding which naturally created a great amount of indignation, alarm, and discontent. After the lapse of some weeks a second General Order was published, regulating the civil appointments held by medical officers and placing the service on such a footing as, in our opinion, more than compensated for the loss inflicted on it by the first General Order. The want of tact shown by the Government in the promulgation of the scheme in two distinct portions instead of one well devised plan was much to be regretted. The discontent excited by these new regulations caused the attention of the officers to be turned to various other points connected with the service which appeared to press unfairly upon them, and these were brought under the notice of the authorities in India and at home. The result of these representations has been that a Royal Warrant has just been promulgated removing certain differences which existed in the grades, relative rank, and regulations respecting promotion and retirement which existed between the British and Indian Medical Services, and the Marquis of RIPON has directed an inquiry to be made into the other grievances with a view to their amelioration.

Of the Naval Service we regret that we have little to say. In the beginning of the year Dr. REID was promoted to be Director-General in succession to Sir A. ARMSTRONG—an appointment which seemed to give much satisfaction to the Department. As yet no steps have been taken to remove the grievances of the medical officers or to hold out any inducement to young men to join the service. We are informed that the subject will be taken into consideration when the estimates are being prepared! Unless considerable modifications are introduced the Lords of the Admiralty may rest assured that the supply of candidates will continue, as it has been during the past year, greatly under the requirements of the service both in number and in quality.

Mirror of Hospital Practice.

In the "Mirror of Hospital Practice" we have endeavoured, as heretofore, to supply trustworthy records of cases illustrating the state and progress of medicine and surgery as practised in the principal hospitals and dispensaries throughout the United Kingdom and the Colonies. Every department of practice has been represented. During the year the notes of between two and three hundred carefully observed cases have been published. All of these possess clinical or pathological interest; some are rare, and a few unique. No pains have been spared to make the records complete, so that their value is more or less permanent. In this attempt we have once more to acknowledge with pleasure

the aid afforded by the various physicians, house-physicians, surgeons, house-surgeons, clerks, and dressers, who have supplied us with notes and other materials. Without this co-operation our task would have been more difficult, and must have been more imperfectly performed. From among reports already selected it is almost invidious to pick out cases for special notice. We may, however, mention the following as among some of the more curious or interesting of the records:—Dr. FUSSELL's case of large sarcoma of the left ilium; sarcomatous thrombosis of the left common and external iliac veins; sarcomatous emboli in the right ventricle of the heart and the right lung, and secondary deposit in the lung, from the Sussex County Hospital; Mr. MORRANT BAKER's five cases of localised scleroderma, from St. Bartholomew's; a case of profuse intracranial hæmorrhage, with intense headache, vomiting, delirium, and glycosuria, but without hemiplegia, and terminating in coma and death, from the Manchester Royal Infirmary; Dr. SINCLAIR's three cases illustrating the difficulties of recognising internal cancer, from the Dundee Royal Infirmary; Dr. FERRIER's case of left-handed epileptic hemiplegia and aphasia, from King's College Hospital; and Mr. WHEELHOUSE's case of aphasia following an injury to the left side of the head, from the General Infirmary, Leeds; Professor SPENCE's three cases of nerve-stretching, from the Edinburgh Royal Infirmary; Mr. BRYANT's series of surgical cases illustrating wound treatment, from Guy's; Mr. ROSE's successful operation for ununited fracture of the olecranon, by opening the joint and wiring the fragment to the ulna, from King's College Hospital; Mr. POLLOCK's case of successful reduction, seventy-two days after the injury, of a dislocation of the femur into the sciatic notch, in a man seventy-two years old, from St. George's Hospital; Mr. BELLAMY's case of amputation at the shoulder-joint for diffuse traumatic aneurism of the axillary artery, caused by rupture of the artery some weeks previously, during reduction of a dislocation of the humerus, from Charing-cross Hospital; Mr. ROUSE's successful removal of epithelioma of the rectum without damaging the sphincter ani, from St. George's; Mr. NEWNHAM's case of dislocation of the foot backwards, from South Staffordshire Hospital; and, lastly, Mr. CHRISTOPHER HEATH's remarkable case of removal of a large epithelioma of the lower jaw and floor of the mouth, in which, two years after the operation, there was no recurrence of the disease, and the patient was in good health.

Medical Societies.

In the various Medical Societies there have been many matters of interest brought forward, some fresh facts and observations added to the slowly-accumulating store, new methods of treatment described, old methods reconsidered, and subjected anew to criticism—all marking the slow but onward progress of our art. Before briefly surveying the work of the year in these bodies, the formation of a new Society deserves especial mention. On June 23rd a meeting was held to inaugurate an Ophthalmological Society of the United Kingdom. The extension of the scientific study of ophthalmology and its bearings on general medicine and surgery justified this step, and the large list of supporters confirmed the idea that its formation supplied a real need. Mr. BOWMAN, F.R.S., was chosen president, and already

two successful meetings have been held, when, in addition to the exhibition and description of cases, papers have been read by Mr. HUTCHINSON, Mr. CRITCHETT, and Dr. HUGHLINGS JACKSON—names representative of the various branches of the profession that have co-operated to the formation of the Society,—At the Royal Medical and Chirurgical Society several papers on surgical subjects have been read. Early in the year Mr. HEATH contributed one on the Treatment of Subclavian Aneurism by the introduction of Needles into the Sac; and more recently Mr. H. MORRIS described a case of External Carotid Aneurism, in which the sac was opened, and the vessel secured on its distal side, after a ligature of the common carotid had failed. Mr. BARKER discussed the subject of Nephrectomy, and Mr. BRODHURST that of the Treatment of Genu Valgum, in which he strongly deprecated osteotomy. On two occasions there have been discussions upon the value of Antiseptics in Ovariectomy, the practice being attacked by the authors of the papers, Mr. LAWSON TAIT and Dr. BANTOCK, and as strenuously supported by Mr. SPENCER WELLS and Mr. KNOWSLEY THORNTON. Amongst other papers bearing on surgery may be quoted one on Syphilitic Stenosis of the Pharynx by Dr. GILBERT SMITH and Mr. WALSHAM, and one on Basic Cavity of the Lung treated by Incision by Dr. D. POWELL and Mr. LYELL. The more purely scientific communications include a careful study of the comparative value of methods of Artificial Respiration in the New Born by Dr. CHAMPNEYS, a research upon Spirillum Fever by Dr. VANDYKE CARTER, an account of the remarkable lack of Amœboid Movements shown by the White Corpuscles in Leuchæmia by Dr. CAVAFY, and a contribution to Teratology by Messrs. WILLETT and WALSHAM, who described minutely a remarkable case of Skeletal Malformation.—At the Pathological Society, in addition to the plan introduced last year of exhibiting specimens without oral communication, the Council devised further means for facilitating the work of the Society by issuing a lengthy catalogue of *desiderata* as a guide to members in their selection of material. It is obviously impossible to particularise the many facts adduced before this Society; suffice it to note the discussion upon the Osseous and Articular Changes in Locomotor Ataxy, opened by Dr. BUZZARD, and the debate, to which three meetings have been devoted, on the subject of Rickets. This debate was opened by Dr. HILTON FAGGE, in a lucid survey of the present state of knowledge upon the subject; followed by a study of the subject of Cranio-tabes by Drs. BARLOW and LEES, who brought forward strong evidence in favour of syphilitic lesion being a chief factor in its production. Sir W. JENNER spoke on the second evening of the debate, and it was evident that but little has been added to the pathology of Rickets since his well-known lectures appeared twenty years ago.—The Clinical Society is always productive of much interesting matter. A report of a committee upon the effects of the Long-continued Use of Chloral was presented early in the year, but its conclusions were not as definite as might have been wished. The subject of Keloid was also reported on by a committee of this Society. The Treatment of Rheumatic Fever by Salicin and Salicylate of Soda was discussed in two papers by the President, Dr. GREENHOW, whose conclusions as to the efficacy of these

drugs in a large number of cases proved to be somewhat discouraging. Dr. GOODHART contributed a case of Rheumatic Fever, which terminated suddenly from cardiac failure whilst under treatment by the salicylate. A debate on Bone-setting occupied the attention of this scientific body on one evening, the subject being introduced by Mr. MARSH. Two novel and successful operative procedures have been brought under notice at this Society—the one, styled “Nephro-lithotomy,” or the extraction of a calculus from the kidney before secondary changes have been set up in the organ, was brought forward by Mr. H. MORRIS; the other, an Extraction of a Villous Growth from the Bladder, by Mr. DAVIES-COLLEY. Both the operations were successful, and met with deserved commendation. The operation of Nerve-suture was illustrated in a case by Mr. HULKE, and that of Nerve-stretching in a case by Mr. GODLEE and Dr. STURGE—the facial nerve being stretched for the relief of facial spasm—with marked success. Dr. LEES and Mr. BELLAMY reported a case of Trephining for Traumatic Epilepsy; Dr. GOWERS discussed the subject of Locomotor Ataxy, especially as regards its hereditary transmission and its relation to syphilis; and two remarkable cases illustrating the subject of Aphasia were contributed by Dr. F. TAYLOR and Dr. HABERSHON, one being a case of destruction of Broca’s convolution and right hemiplegia without aphasia, the other of left hemiplegia with aphasia. Both the patients were left-handed.—At the Medical Society the Lettsomian Lectures were delivered by Mr. TEEVAN upon the Treatment of Stricture, Enlarged Prostate, and Stone in the Bladder; the annual Oration by Dr. BROADBENT on the Pulse. A Committee of the Society reported upon Arsenical Poisoning by Wall-papers and Fabrics, and further inquiry was resolved upon. Amongst the prominent communications may be mentioned those by Dr. H. JACKSON on Cerebellar Tumour and on Recovery from Symptoms of Organic Brain Disease; a paper by Dr. ORD on the Treatment of Thoracic Aneurism by Galvano-puncture, and by Dr. BROADBENT on Pleural Effusion. One evening was devoted to a debate on the Lunacy Laws, and attracted considerable attention.—The lecturer this year at the Harveian Society was Dr. J. E. POLLOCK, who discussed the subject of Phthisis.—At the Obstetrical Society the most notable papers discussed were one by Mr. LAWSON TAIT on the Rotation of Ovarian Tumours; one by Mr. KNOWSLEY THORNTON on the Removal of Fibroids by Laparotomy; and cases of Extra-uterine Fœtation by Drs. BRAXTON HICKS, FOULCHER, and CARTER. Dr. GRAILY HEWITT contributed an analysis of a series of cases of Uterine Distortions and Displacements, and Dr. POOLE a case of Congenital Dislocation of both Hips.—At the Epidemiological Society a paper by Dr. JAMES EWART on Enteric Fever in India gave rise to a lengthy discussion. Indian diseases were also illustrated in papers by Dr. CHEVERS on Relapsing Fever, and by Dr. FRANCIS on the Plague.—There have appeared also from time to time in our columns reports of the Medical Officers of Health Society, and of the Association of Surgeons Practising Dentistry. It will be seen from the foregoing summary how varied have been the subjects chiefly dealt with in the past year, and although indicating only those which seem to be the more important, it must be borne in mind that many other communications have been

read of almost equal interest, the whole forming strong evidence of the flourishing condition, as well as the popularity, of the Medical Societies.

The Medical Council.

The Medical Council met in July and displayed boldly all the faults of its constitution and system of procedure. For probably the twelfth time it traversed the whole field of preliminary education, making Sir WILLIAM GULL exclaim, "We fight our battles three times over, and never come to any result: we shall go on for ever,—yes, for ever, till time shall be no more." This discussion lasted nearly a week, and embraced nearly every question in preliminary education, from the merits of Greek to those of Dutch. Nearly at the close of the meeting, Mr. SIMON carried a resolution recommending that an examination be imposed on students in the rudiments of natural science—physical, chemical, and biological. This examination is to be placed after the General Preliminary Examination, and either before beginning the medical curriculum, or at the end of the first year. It will not be for want of recommendations and examinations if the medical student of the future is not perfect. Mr. SIMON sought to get from the Council an expression of opinion in favour of urging on the Government the desirableness of deciding their course with regard to medical legislation, with the view of terminating "a period of indecision and unsettlement;" his motion was seconded by Dr. QUAIN, but it was lost. The Council evidently believed that the change of Ministry was somehow in their favour, and that if they can prolong "the period of unsettlement" the question will be abandoned in their favour. It is pitiable to see a public body so criticised and so little respected, and yet so willing to live on in helpless inefficiency. We need not notice further a meeting lasting nine days under circumstances of "unsettlement" which would have justified a formal meeting of a few hours.

Medical Associations.

We cannot bestow more than a passing notice on the work of the Medical Associations. The British Medical Association met at Cambridge, under exceptionally favourable circumstances. A very grateful feature of the meeting was the presence of the venerable Professor GROSS of Philadelphia, setting younger men an example of vigorous interest in science at an age long before which they are apt to become indifferent and selfish. Honorary degrees were conferred on those, for the most part, who had similar honours conferred by other Universities, but with a singular want of originality and boldness. The meeting was signalised by a large concourse of distinguished members and visitors, by several addresses of exceptional interest, including the Presidential Address by Dr. HUMPHRY; the address on Medicine, by Dr. BRADBURY; on Surgery, by Mr. TIMOTHY HOLMES; the address in Physiology, by Dr. MICHAEL FOSTER; in Psychology, by Dr. J. CRICHTON BROWNE, and that by Dr. W. S. PLAYFAIR at the opening of the Obstetric Section. An address in the Pathology Section by Sir JAMES PAGET, entitled *Elemental Pathology*, emptied all the other Sections, and suspended other business. This Section was also favoured by an able summary from Mr. LISTER of the Investigations of KOCH on Septicæmia and Gangrene, and of the discovery of the nature of the so-called Fowl Cholera by M. TOUSSAINT.

Guy's Hospital.

There are a few special questions or events in every year without notice of which any summary would be incomplete. In the present year we have to mention with regret a disturbance of the harmony of one of our large endowed Metropolitan Hospitals, which threatens even yet to mar its historical usefulness and fame, and has already produced the resignation of its two senior medical officers, Dr. HABERSHON and Mr. COOPER FORSTER. This discord began in an attempt on the part of the Treasurer and Governors to make fundamental changes in the nursing system of the hospital without previous consultation with the medical officers, who are as vitally interested in the efficiency and subordination of nurses and nursing as in the quality of the quinine, or of the chloroform which they prescribe. As if to accentuate the scandal of a nursing system acting independently of the medical staff, two cases came to light which greatly shocked public feeling. One, that of a patient with chronic phthisis, who was subjected to a cold bath for an hour by one of the nurses, partly apparently with a penal view, and with a slight notion that it would do no harm therapeutically. Very shortly after symptoms of acute mischief in the head appeared, and soon proved fatal. The nurse was found guilty of manslaughter. In a later case a man was brought to the hospital after a fall, with a slight scalp wound. He was seen and the wound dressed by a nurse slightly. The next day he was brought back to the hospital and found to have fracture of the skull, of which he soon died. The controversy which took place between the Treasurer and the Governors, upholding the new nursing system on the one hand, and the medical men on the other, has occupied most of the year. On the part of the Treasurer and Governors it has been disrespectful and highly unmindful of what was due to the medical faculty of a hospital which has been made famous at home and abroad by its medical faculty. On the part of the medical staff there has been a want of decision, strength, and, we had almost said, self-respect; but it would be more proper to say respect for the profession they represent. Although, however, the senior medical officers have resigned, the public scandal remains of a great hospital so badly administered financially that it is deeply in debt, that nearly a hundred beds have had to be closed, and that by a system of self election on the part of the Governors medical men have gradually been ousted from the Board of Management, and that the admission of two is now conceded as a sop to public and professional indignation. Clearly, we have not got to the end of the crisis at Guy's, which discredits the year 1880. But good will yet come out of it.

Medical Politics.

Progress in medical legislation was abruptly, but we hope only temporarily, checked by the unexpected dissolution of Parliament. The Select Committee on Medical Bills had commenced its work and took the evidence of Professors STRUTHERS and GAIRDNER, setting forth, as Professor TURNER had done before, the important work being done by the Scottish universities, and their not unreasonable anxiety that it should not be unduly interfered with by legislation, which the Profession feels to be so necessary for reducing the competition and the inequality in Medical

Licensing Boards. The fall of the old Parliament had at least this disadvantage, that it deprived medical men of the services in Parliament of Dr. LUSH, Mr. MILLS, and others who had heartily and ably helped the cause of Medical Reform. The new Parliament happily includes new medical members, who will, we believe, prove worthy successors of WAKLEY, BRADY, CORRIGAN, LUSH, and others. The new Government had not been long in office before it was interrogated on the subject of its intentions in regard to amendments of the Medical Acts. The tone of the answer of the Lord President and the Vice-president was regarded as somewhat discouraging. But there is reason to believe that Mr. MUNDELLA at least was misunderstood, and that nothing more is wanted than an unmistakable expression of the feeling of the profession to induce the Government to complete the work begun by two preceding Governments. The state of Ireland involved some questions of medical interest, but, thanks to the progress of time and of Government, we were spared a repetition of the diseases of famine on anything like the scale of the historical fevers of 1845. Various other questions of medical interest were touched but not disposed of, some of which are noticed elsewhere, the most important of these being the present shape of our Vaccination Laws.

Medico-Legal Cases.

The medico-legal history of the past year is marked by several cases of more than ordinary interest. In February LEWIS J. PAINE was convicted of manslaughter for encouraging a wretched woman with whom he lived to consume inordinate quantities of alcoholic drinks and of thus compassing her death. He was sentenced to penal servitude for life. The case is remarkable because the lethal agent was a common article of diet which the prisoner consumed in quantities nearly equal to those with which he plied his victim. The case of HOWELL *v.* WEST, in which the parent of a boy at the Epsom College brought an action against the head-master and medical attendant of the college to recover expenses in connexion with his son's illness and death, which were alleged to have been due to the carelessness of those who had the charge of him, ended in a verdict for the college authorities. The celebrated case of BAGOT *v.* BAGOT, which had been pending for two years, ended in a compromise. It will be remembered that in consequence of BAGOT suffering from locomotor ataxy in a marked form, it was alleged that he could not be the father of his wife's child, and that therefore the will which he had made, almost disinheriting the child in question, was right and proper. The inquiry at the Cork Fever Hospital into the charges preferred against Dr. MACNAUGHTON JONES of performing "a dangerous operation" (the hypodermic injection of pilocarpin), and thereby causing the death of a patient, happily showed these charges to be altogether groundless and vexatious, but the case serves to show the annoyances to which a conscientious physician may be subjected. The trial of PLEASANCE LOUISA INGLE, a nurse of Guy's Hospital, for the manslaughter of a patient and the many unpleasant facts connected therewith, is too fresh in the minds of our readers to need even a word. Three of the cases mentioned above showed that those who practise medicine and surgery must be prepared to justify their acts. In the cases of HOWELL *v.* WEST and REGINA

v. INGLE members of the profession were brought into antagonism with each other in a manner which was greatly to be regretted, and will cause the year 1880 to dwell unpleasantly in the memory.

Sanitary Legislation and Administration.

With regard to public-health matters, two events occurred during the year which peculiarly mark it. We refer first, to the acceptance by the Local Government Board of a duty of cultivating animal vaccine lymph for the public use; and, second, to the introduction into Parliament, by the President of the same Board, of a Bill for relieving persons objecting to vaccination of the discomfort arising from recurrent penalties under the existing vaccination law. The year opened with the professional discussion as to animal vaccination, its merits and demerits, in full swing. In this discussion the profession had the advantage of Dr. WARLOMONT'S assistance, who brought to their aid, in coming to a sound conclusion, the results of his unique experience in Belgium. Dr. CAMERON, M.P., moreover, who had been chiefly influential, by his introduction of the subject into the House of Commons and his ventilation of it in the public press, in bringing the matter to a crisis, helped. The Local Government Board also, recognising the importance of the discussion, delegated Dr. BALLARD to represent in it the Central Government aspects of the question. At first there was some danger of the discussion lapsing into side issues, but eventually it became evident that there was no substantial differences of opinion among all the parties taking part as to the advantages to be derived from the introduction of animal vaccine into the national system of lymph issue. It was impossible for the President of the Local Government Board to resist the weighty professional opinion brought to bear upon him, and Dr. CAMERON had the gratification in the course of the last session of Parliament of eliciting a promise from Mr. DODSON that his department would make arrangements for the issue of animal lymph from the National Vaccine Establishment. Whatever these arrangements were to be, they do not appear to have been yet completed; but Dr. CAMERON will soon have the opportunity of ascertaining what stops the way. After showing this tendency to advance in his department, Mr. DODSON curiously enough revived the Vaccination Amendment Bill which had been introduced into Parliament several years ago by Mr. FORSTER, and which embodied certain conclusions of the last Parliamentary Committee on Vaccination. The Bill had for its object to relieve objectors to vaccination from repeated penalties for neglecting vaccination, and this by exempting from further penalty persons who had once paid the full penalty that can be inflicted under the law, or who had been fined twice in a less sum. It provided, in short, a cheap and easy mode of freeing the objector from the operation of the law, the child remaining unvaccinated. It is not often that the profession as a body has shown such community of interest and manifested so earnest a desire to save the public from what it believed to be an error in policy, as in this case. Through its recognised corporations and associations, and in conjunction with representatives of almost every branch of the scientific world, it appealed so forcibly and with such cogent reasons to Mr. DODSON that the Bill was withdrawn. It is

greatly to be wished that the energetic action displayed by the profession in this case could be more frequently observed in matters more directly affecting its own interests.

The attention of the profession and of the public has been much and increasingly occupied during the year with the consideration of infectious diseases and the means for their limitation. The subject of the influence of schools in disseminating those diseases has particularly claimed attention. It is to be feared that the compulsory clauses of the Education Act while securing the object primarily aimed at, have indirectly and unexpectedly tended to a greater development of certain infectious diseases. This was probably a necessary consequence of the more certain gathering together of children in larger numbers in schools; but we have little fear that as this matter becomes clearer, medical officers of health will see their way in practice to counteract the evil, and that legislature will support their efforts in this direction. In Local Acts powers are being taken by Sanitary Authorities for the closure of schools in view of certain extending epidemics, and we have little doubt that this local legislation indicates the line in which general legislation, in this respect, will ultimately take on the subject. In connexion with this subject it may be mentioned that five corporations—to wit, Huddersfield, Lancaster, Oldham, Preston, and Stafford—obtained Local Acts including provisions for the more effectual dealing within their boroughs with infectious diseases. The provisions are, as a rule, similar to those granted to other corporations in preceding sessions of Parliament, providing especially for the notification of infectious diseases, but there were diversities which still further show that it is high time this form of legislation in regard to these diseases came to an end. It is a form which must clearly add, and is, indeed, adding, to the already sufficiently complicated character of our sanitary law. Moreover, this sort of legislation granted indiscriminately to corporations, whether they have means for giving effect to it or not, may end in bringing sanitary legislation on the subject into discredit. For it is unlikely that local authorities who have failed to exercise the comparatively slight powers in respect to infectious diseases they possess under the Public Health Act, 1875, will carry into effect the extensive powers they obtain under a Local Act.

No general legislation directly of a sanitary character took place during the last session of Parliament. The administration of the Local Government Board, notwithstanding a change of Presidency consequent upon the change of Government, calls for no particular remark on the public health side other than we have already made in respect to animal vaccination and the Vaccination Amendment Bill brought forward by Mr. DODSON; and on the poor-law side nothing occurred as affecting the medical aspects of the poor-law which requires special notice. It is remarkable, having regard to the too general defective sanitary and medical administration of workhouses, how the Board continues to escape from an endless series of public scandals in this matter. The resignation of Dr. E. C. SEATON as Medical Officer of the Local Government Board, quickly followed by his lamented death, took place early in the year. Dr. BUCHANAN, the Assistant Medical Officer under Dr. SEATON, was appointed Medical Officer to the Board in Dr. SEATON'S place,

and Mr. NETTEN RADCLIFFE succeeded Dr. BUCHANAN as Assistant Medical Officer.

Two questions concerning the public health aspects of disease occupied chief attention in the course of the year. The first question related to a discovery by Mr. W. H. POWER, of the Medical Department of the Local Government Board, that an outbreak of simulated enteric fever on board a school-ship in reality was a form of parasitism, at first suspected to be trichinosis, or like trichinosis in character, but afterwards shown to be of an unknown nature. This discovery has opened up a new field of research in parasitism, and we wait the results of its further cultivation with great interest. The second question related to an outbreak of fatal anthracoid disease among persons engaged in sorting wool in Bradford and Yorkshire. An account of this outbreak, written at the time, has been given in THE LANCET in certain remarkable papers from the pen of Dr. BELL, of Bradford (to whom the merit principally attaches of having worked out the real nature of the affection known locally as "woolsorters' disease"), and we look for a further history of the outbreak from the pen of Mr. JOHN SPEAR, of the Medical Department of the Local Government Board, who investigated the matter for that department of the Government. The pathological inquiry regarding the outbreak was carried out by Professor GREENFIELD, of the Brown Institution, and we have quite recently had the gratification of hearing the results, and of their relation to the whole question of Anthrax from his lips in the lectures he has delivered at the University of London, which ended only this week, and which are now appearing in the columns of THE LANCET. It would be difficult to exaggerate the interest and suggestiveness of these lectures, not only with reference to the pathology of anthrax, but also with reference to several questions of epidemiology of the profoundest moment. This is not the place to comment on the results of Dr. GREENFIELD'S observations, and the observations of others in the particular teachings of the pathological laboratory as to anthrax. Let it suffice to say that for the first time there was presented to the eye and ear in the course of his lectures the whole probable history of the origin, development, increase, decrease, and cessation of a virulent epidemic disease peculiar to animals, but apt to be propagated to man; and a clue was obtained to a line of research touching virulent epidemic diseases generally of the greatest promise. Moreover, it was clearly shown by Dr. GREENFIELD that questions of etiology were not alone concerned in his observations, but that these tended to confirm the researches of other observers that there was being developed side by side with our knowledge of the intimate nature of certain epizootic diseases a knowledge of a prophylaxis similar in character to that which vaccinia exercises upon small-pox. In other words, that it has become possible in the laboratory to cultivate the virulent poisons of the diseases referred to, so that they may by inoculation become protective against their own virulence.

The report of the medical department of the Local Government Board, published during the year, is especially noteworthy for containing the last and concluding part of Dr. BALLARD'S report on "Effluvium Nuisances." It is a curious comment on the administration of the Local Government Board that this remarkable and unique work

has not been published in a separate form. It is distributed through three annual reports of the medical department, and has been published in these reports almost regardless of cost; yet no attempt has been made to bring the several parts together and make them readily accessible for the purpose for which they were intended. The Board has evidently spared no money to perfect the inquiry as far as practicable, but the inquiry being completed and the results invaluable, the Board is careful that the results shall be got at only with difficulty!

No international questions relating to disease obtained much prominence during the year, but the National Board of Health raised a question of what may be called (following Dr. BOWDITCH'S phrase) the Sanitary Organisation of Nations, which may bear fruit hereafter. Of metropolitan health-questions, difficulties accompanying the execution of the Artisans and Labourers' Dwellings Acts and the proposed purchase of the interests of the Water Companies by the Government had the chief place. The former difficulties are still under consideration, and may be a subject for legislation during the coming session of Parliament; the scheme for the purchase of the Water Companies' interests fell through, but this question is pretty sure to come to the front again.

Almost as we write Dr. ALFRED CARPENTER and others are encouraging hopes (let us trust not tantalising) that the amelioration of that abomination of abominations, a London fog, is a possibility. London fog was a most deadly element in the history of 1880. The deaths from diseases of the respiratory organs, registered in London in the week ending Feb. 7th, were 1557, being in excess of the weekly average by no less than 1125! We have to thank Dr. ARTHUR MITCHELL of Edinburgh for the prominent attention which this subject has received of late. In a paper of his which appeared in the course of the year on the influence of the protracted fogs of the winter of 1878-79 on the mortality of the metropolis, he showed how disastrously they had aggravated the mortality from respiratory diseases. This paper excited great notice, and proved that much more serious inconveniences than discomfort and dirt were accompaniments of a London fog, and is causing serious efforts to be made with a view of securing the abatement of this grave nuisance.

The Epidemiological Society, under the Presidency of Sir JOSEPH FAYRER, has displayed great activity. Of the numerous important subjects it has had under consideration we may signalise especially the question of "enteric fever" and "fevers" of tropical climates. Papers were read on these fevers by Surgeon-General GORDON, Surgeon-Major DON, and Deputy Surgeon-General EWART, and a special evening was devoted to their discussion. The interest of the discussion rested mainly in the apparent divergence of views on the subject of enteric fever entertained by medical men of wide experience in India and the tropics and medical men of home experience. But it appeared that even a wider divergence existed among men of large Indian and tropical experience, and among certain of them than among the former, and men of home experience. The discussion inevitably suggested that the divergence signified wide differences in the methods of investigation pursued, and also in the phraseology made use of.

Commissions.

Early in the spring we appointed a Commission to inquire into the working of the new Sick Infirmaries attached to the Metropolitan Workhouses. The result of this inquiry showed that considerable care and attention had been bestowed on the arrangement and construction of these institutions; but our Commissioners pointed out that the medical and nursing staff fell very short of the requirements for efficiently dealing with cases of acute sickness arising among the sick poor. Our Commissioners expressed an opinion that the medical staff should be strengthened by the appointment of clinical assistants, and thus, by relieving the medical superintendent of much unnecessary work, permit him to give more attention to serious and urgent cases. They also recommended that the nursing staff should be largely increased. One point particularly was brought into prominent notice in the course of this inquiry, and that was, how important a factor sickness was among the working classes in the production of pauperism. Our Commissioners demonstrated the proposition that we have so frequently enunciated in these columns, that the sick poor will not, till the last extremity, submit to be pauperised by admission to these infirmaries so long as they can maintain the struggle outside. In consequence of this reluctance, much valuable time is lost in the treatment of disease in its earlier stages, and the case has often assumed a chronic and hopeless form before it is admitted into the sick asylum, where it remains a burden upon the rates for months, or even years, whereas if it had come under observation at an earlier period the catastrophe might have been obviated. A classification and separation of the *sick poor* from the *sick pauper* in these institutions is urgently called for. Recognising the national interest now attached to athletic pastimes, we have during the present year directed attention to some points of interest in these pursuits. Hitherto our remarks have been limited to suitability of various kinds of exercise for individuals under different conditions of life. In the forthcoming articles the various systems of training will be contrasted, and we shall endeavour to enunciate a system that shall fulfil all strictly physiological requirements, with special reference to individual idiosyncrasies. In our introductory article on the subject of Athletics generally we pointed out the revolution the sliding seat was likely to make in the art of rowing, and predicted that increased length of slide, with a slower stroke, would enable the oarsman to bring increased muscular effect to bear on his work, and so increase his pace. This statement has been borne out by the result of the recent race for the championship of the world between HANLAN and TRICKETT, the former, with an increased sliding range of seat and with a considerably slower rate of stroke, easily defeating his opponent, who was the taller and more powerful man. Feeling strongly that the use of Wines as therapeutic agents, and as stimulants and cordials by the convalescent, does not rest on precise principles, we have appointed a Commission to conduct a new series of medical and chemical investigations. Some of the reports of this Commission have appeared, and others are in preparation. We have also collected materials for a special report on Schools, which are now under consideration, and will shortly form the subject of special articles in THE LANCET.

Obituary.

It is never a satisfactory part of a summary to recall the losses of the year. This year is no exception, for it has taken away many whose labours have made momentous additions to medical knowledge, and many more whose medical practice entered into the local history of their respective neighbourhoods. We scarcely know how to select from names so representative. But a few will suffice to show how great the losses are. HENRY HANCOCK, J. A. LOCKHART CLARKE, EDWARD CATOR SEATON, DOMINIC CORRIGAN, ALFRED SWAINE TAYLOR, PAUL BROCA, FERDINAND R. V. HEBRA, ROBERT CEELY, WILLIAM BUDD, Deputy Inspector-General EDWARD GOODEVE Dr. ALFRED HUDSON, EDWARD CARR JACKSON, Dr. JOHN DEAKIN HEATON, J.P., Leeds, HENRY FRANCIS BURDETT of Birmingham, EDWARD AMPHLETT, M.A., M.B. Cantab., Deputy Inspector-General JOHN STIRLING, M.D., Surgeon-Major J. B. HANNAH, at Naini Tal, J. PEARSON IRVINE, M.D., EDWARD ISAAC SPARKS, M.B. Oxon., Surgeon-Major BRYDEN, of the Bengal Army, &c. Many practitioners have died ripe in years and honour, like Mr. LONG of Liverpool, or Mr. WM. JOY, of whom it was said that he practised fifty-five years at Northwold, never having had, or wished for, a holiday in thirty-five years save that necessitated by an attack of typhoid; or like Mr. BATEMAN of Islington, who worked fifty years with only an annual fortnight of holiday, to which he was compelled in his early life by recurrent attacks of hæmoptysis; or like Mr. MICHAEL FOSTER of Huntingdon, whose name and virtues are so happily perpetuated. Some have died in their comparative youth, like Dr. SIMPSON of Netley, or in the midst of their life and usefulness, like Dr. FAIRBANK of Windsor, or Dr. WILLIAM LAUDER LINDSAY of Perth. Some have come by their death in arduous conflicts with plague and climate, like JOHN McDONALD of Buenos Ayres, who was left out of three medical men in a population of 150,000 stricken with yellow fever; some have died with the din of battle in their ears, bravely and at their post, and lie in Afghan cemeteries, like Surgeon-Major JOSHUA HENRY PORTER. Seldom has it been more difficult to do justice to the dead than in looking over our obituary for the year 1880.

In taking leave of our readers for the year 1880, we do so with all good wishes and with good heart. The social and commercial conditions of the country at large are improving. There are evils actual and threatening, but they are chiefly such as can be prevented by individual restraint and wise laws. It only needs that statesmen and individual men and women should take counsel a little more frequently of those whose business it is to study the great laws of health, as well as those of disease, to secure an unprecedented exemption from disease and an unparalleled development of national virtue and health. The days are gone for associating the calling of Medicine with disease. Our association is with health. As a profession, we urge on all movements for its preservation, and when lost, for its recall, and for the restriction of the movements of disease.

MR. LUTHER HOLDEN a few days since delivered his last Clinical lecture at St. Bartholomew's Hospital previous to retiring from the post of acting surgeon to this institution, after a service of more than forty years.

Annotations.

"Ne quid nimis."

THE DEBATE ON RICKETS.

THE adjourned discussion on Rickets was concluded at the meeting of the Pathological Society on Tuesday last. From lack of space this week, we must postpone a full consideration of the subject until our next issue. We certainly share the President's disappointment at the almost entire barrenness of the debate in facts of any kind, and particularly new facts. Theories, opinions, and suggestions have been freely expressed and exchanged, and in this way no doubt the ground has been cleared for future workers, and we may fairly hope, with Dr. Fagge, that the real result of the discussion will be found in the new interest awakened in the subject, and in the stimulus and point it will give to investigation. It has been thus with other of the formal discussions at the Societies; they have been starting-points rather than winning-posts, in which old cumbrous and useless nomenclature, and the various text-book impedimenta of accumulated unsupported views, have been disposed of; or, to change the simile, they have been destructive rather than constructive. Those who hope that they can be other than this must be disappointed, although the ultimate result may thoroughly demonstrate their value.

FOOTBALL ACCIDENTS.

THE late fatal football accident has naturally given rise to many remonstrances against the importation into a pastime of rules which seem to involve an undue amount of danger. The regulation of such matters we must leave to our sporting contemporaries, but we would remark that, while we deprecate unnecessary and unmeaning risks of all kinds, a certain danger is inseparable from all athletic sports. The cricket-field, the hunting-field, the race-course, the racket-court, and the arena of athletic sports, all number a good many maimed, or even killed, among their votaries, but the undoubted value of athletic exercises to the individual, and the nation, more than counterbalances the occasional mishaps which must inevitably occur. While it is advisable to avoid anything approaching to brutality in our pastimes, it is equally necessary not to encourage effeminacy, especially in this age when manufacturers of "gentlemen's corsets" flaunt their advertisements in the public press, and men of the modern æsthetic school write maudlin poems in praise of each other. There are many pastimes infinitely more ruinous to health than those we have enumerated above. Dancing night after night in crowded non-ventilated rooms is among the most unwholesome and dangerous practices of modern life, and kills infinitely more persons (though more indirectly) than either the "Rugby" or the Association Rules. The men who are killed by sitting in public-houses, or (what is very much the same thing) in club houses, playing billiards or cards till the small hours and drinking "B. and S.," are not held up as warnings, while their fellows who happen to be killed while engaged in some sport which has in it a dash of nobility and pluck, are spoken of as "frightful examples" of the evils of this or that amusement. If by undue roughness or by unfairness one man kills another at a game, the ordinary law is sufficient to deal with him. This is enough protection, and we very much object to a return to anything approaching the sumptuary laws of a bygone age. The science of medicine has lately had its liberty seriously curtailed by sentimentalists. We shall very soon be restricted in our choice of diet by the followers of Sir Wilfrid Lawson. Only last session an absurd Bill about acrobats met with a certain amount of favour in the House of Commons, and if a stand be not made our Imperial Vestrymen, whose watch-

word—save the mark !—is “Liberty,” may be asked to regulate the method to be pursued in kicking a football, and impose a limit on the growing prowess of the rising generation.

THE ALBERT MEDAL.

WE have much pleasure in announcing that Her Majesty the Queen has been graciously pleased, on the recommendation of the Prime Minister and the Secretary of State for War, to award the Albert Medal for saving life to Surgeon Henry Grier, of the Army Medical Department, for his gallant and heroic conduct in endeavouring to save the life of the late Lieut. Graham, 2nd Battalion 10th Regt., stationed at Malta. Mr. Graham was suffering from diphtheria in the most virulent form, and had undergone the operation of tracheotomy for relief of some of the most urgent symptoms; the tube became blocked, and suffocation was imminent, when, other efforts having failed, Mr. Grier, at imminent risk, sucked the poisonous matter and diphtheritic membrane from the wound, and succeeded in restoring the life of his patient. Mr. Graham unhappily succumbed a day or two afterwards from exhaustion and extension of the disease. Mr. Grier is, we believe, the first member of the medical profession on whom the Albert Medal has been bestowed, and we congratulate him heartily on the honour which has been conferred on him, and through him on the medical service of the Army.

HERBALIST'S SURGERY.

AN important case came before the Coroner's Court at Old Basford on the 8th inst., which from its surgical and medico-legal aspects is alike important. From the report in the *Nottingham Daily Guardian* we gather that a man, thirty-seven years of age, was suffering from some trouble in connexion with his bladder or urethra, and on hearing from a friend of his—Mr. Marlow, a herbalist—that if sent for he could do him good, he sought his aid. The herbalist “attempted to draw his water, but instead of that drew blood.” Mr. Maltby, a surgeon, was then called in, and found the man collapsed, in great pain, and passing bloody urine; he quickly developed symptoms of peritonitis, from which he died. At the autopsy no urethral stricture was found, but there was a false passage, about three inches long, from the urethra, and piercing the neck of the bladder, which was probably the exciting cause of the fatal peritonitis. It is obvious that considerable violence must have been employed in this case, and while forcible catheterism is not justifiable, even where the passage is obstructed by a stricture, it is still less pardonable where there is no obstruction at all. The fact that skilful surgeons sometimes make false passages in front of tight strictures has no bearing whatever on such a case as this, where there appears to have been no obstacle whatever to the passage of an instrument properly used. The surgical point in the case, however, is obvious, and we need not further allude to it. The coroner was at great pains to instruct the jury as to the principles by which they were to be guided in coming to their verdict, which was that the man died from peritonitis. It is to the coroner's law that we would specially call attention. He said “a mistake had been made,” but that Marlow could not be held to be criminally responsible. He argued that as the operation of passing a catheter has been done very frequently by patients for themselves, it was an operation which an unskilled friend was qualified to do for the deceased. But he seems to have lost sight of the fact that Marlow offered his services to the man with the assurance that he could relieve him, and there can be no doubt that he gave the patient the impression that he was skilled in the treatment of such cases, and professed to be qualified to pass a catheter. Had he possessed a qualification to practise, an action for malapraxis would undoubtedly have laid against him.

A VETERINARY COLLEGE FOR IRELAND.

A DEPUTATION has waited upon the Lord-Lieutenant for Ireland, urging upon him the necessity for establishing a Veterinary School in Dublin, to supply the requirements of the sister island. The veterinary profession does not appear to have been represented in the deputation, nor do its wishes or views seem to have been obtained. The principal speaker certainly gave evidence of this in the very inaccurate statements he made on the subject, some of which were calculated to mislead. Veterinary schools in England and Scotland are self-supporting, and receive no Government assistance; but the Government is now asked to give a grant of £10,000 to commence this school, which, we feel assured, unless annually subsidised by large sums, could not exist for more than two or three years. It is also desired that the proposed school shall be empowered to grant licences to practise veterinary medicine. We look upon this request with the gravest apprehension. No medical school should be allowed to license its own students; and the Government has hitherto refused this privilege with regard to veterinary surgery, application having repeatedly been made by the Highland and Agricultural Society of Scotland for power to grant diplomas to veterinary surgeons, which was declined on the ground that the Royal College of Veterinary Surgeons was alone competent to examine and license students. The Royal College, the body corporate of the profession, has an examining board in London, Edinburgh, and Glasgow, and could also establish one in Ireland if necessary. In such a small body as the veterinary profession two or more diploma-conferring bodies would simply mean a low standard of professional education; and as this is not beneficial to owners of animals, nor yet to the animals themselves, much less to the profession, the request should be resisted.

We even seriously doubt whether there is any necessity for a veterinary school for Ireland, for the simple reason that that country can support very few veterinary surgeons; even at the present time there are many there who cannot obtain a living from the practice of their profession. They receive no countenance at all in some parts of the country by boards of guardians and others who have the bestowing of different appointments, political and religious prejudices largely influencing them. From these, and also from motives of economy, quacks and unqualified men are only too often preferred to veterinary surgeons who may be residing in the same district. From what we can learn, the supply of veterinary surgeons in Ireland is much more than equal to the demand, and to add to the present sources of supply would only increase the inconveniences and drawbacks already existing. The application has been made without due consideration, and we would suggest the collecting of evidence and obtaining the opinions of those most competent to judge, before committing the country to a new cause of expenditure, and injuring a profession which is now, by its one-portal system of granting degrees, beginning to make rapid strides.

One thing is certain—that if a school is maintained in Ireland at the public expense, the schools in England and Scotland will have strong claims also for subsidy, and will undoubtedly demand it.

DR. RICHARDSON AND THE LONDON SCHOOL BOARD.

DR. RICHARDSON has distinguished his election to the London School Board and his entry upon the duties which appertain to the members by saving the Board, if not from impending suffocation, at least from suffocative procedures. Before he had well settled down into his seat at the Board, Dr. Richardson discovered that the Board-rooms, notwithstanding the happy position of the building in which it is

situated, is so imperfectly ventilated as to threaten the members with dangerous results to their health. Dr. Richardson says nothing of what the results must have been, short of obvious evil physical consequences to the members, upon the mental deliberations of the Board; but it may be inferred, so energetic has he shown himself in the matter, that he objects to take part in deliberations of which it would be difficult to say how much of the results came from natural cerebral action, how much from foul air acting upon the cerebration. There is something particularly absurd in the conception of the chief Educational Body in the metropolis carrying on its functions under circumstances deleterious alike to sound health and clear thought for a period of several years, *without having discovered it*, and that the discovery should have been left to be made by the casual importation of a new member. The Board has reason to congratulate itself upon the election of Dr. Richardson, not only from the additional weight his presence will give to many of its deliberations, but also from his having already saved them (or being about to save them) from certain sanitary shortcomings which have unwittingly been permitted in the Board's official residence. The incident suggests that the Board would do well to ask Dr. Richardson to make a sanitary survey of the numerous new schools which have sprung up under their auspices, and which externally at least recall the premises on the Thames Embankment.

THE following resolution was unanimously passed on December 9th, 1880, by the East Surrey district of the South Eastern branch of the British Medical Association at a meeting held at Croydon:—"That this meeting desires to express to Dr. Habershon and Mr. Cooper Forster its sympathy in the painful circumstances which have led to their withdrawal from the staff of Guy's Hospital; and its appreciation of the manly spirit which has induced them to resign their respective appointments, sooner than submit to a loss of professional dignity, or sanction changes which they believed to be detrimental to the interests of the patients entrusted to their care."

At a meeting of the Master and Fellows of Gonville and Caius College, Sir George Burrows, M.D., F.R.S., and George Budd, M.D., F.R.S., members of the College, were elected Honorary Fellows of the Society.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Huntingdon (Registration District).—Scarlet Fever.—This report, from the pen of Dr. Parsons, gives the result of an inquiry into the recent prevalence and long continuance of scarlet fever in the urban sanitary districts of Huntingdon and Godmanchester, and the extension of the disease (as it was feared) from the urban districts into the rural sanitary district of Huntingdon. The report presents a curious picture of the sanitary negligence obtaining in the urban districts, and the practical lapse of the public health law there in many things, as also to a great extent in the rural district. For example, Huntingdon has an old so-called "pest-house," available for use as an infectious disease hospital, but which is given up for residence to a man with a family, and which, during the whole continuance of the scarlet fever, was not used for the isolation of a single case, because, for one reason among others, the occupant had a family of young

children who might become infected. Neither Godmanchester nor the rural sanitary authority possesses hospitals. Recommendations how to deal with epidemic disease seem powerless when some of the most ordinary measures for the sanitary administration of a place are in default, seem purposeless, particularly when it appears pretty obvious that nothing short of an epidemic of cholera or plague would arouse the local authorities to a proper sense of their sanitary responsibilities. Dr. Parsons, nevertheless, makes recommendations, the necessity for which must have been as well known to the authorities before his visit as after. The threatened extension of scarlet fever into the rural sanitary district appears happily to have ended without any serious consequences; but we should have been glad to have known how Dr. Parsons, who has had previous large experience of the needs and difficulties of a rural sanitary district, would have carried into practice his recommendations to the rural sanitary district. Beneath our breath be it whispered (if a pen for the moment be assumed to breathe and whisper) the reports of the medical department have not hitherto given us much light in this direction. The department is getting too much into the habit of stating merely the requirements or permissions of the law, not suggesting how the requirements may be met. Perhaps we may get more practical light on the subject of isolation when Dr. Thorne Thorne completes the inquiry as to sanitary hospitals, on which he is now engaged.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Brighton.—The report of the medical officer of health for Brighton, Dr. Taaffe, for the quarter ending September 30th, shows that the births equalled an annual rate of 28.6, and the deaths of 22.8, per 1000 of the estimated population. The report gives particular attention to the subject of the mortality from diarrhoea among infants and young children, and enters into a detailed statement of the sort of feeding which the infants had who died of diarrhoea during the quarter. In the year 1875 Dr. Taaffe carried out a similar inquiry with reference to fatal cases of diarrhoea among infants during the summer quarter. The results of the two inquiries substantially confirm each other. The great majority of the infants were artificially fed, and of the few fed at the breast several were subjected in a measure to the evils attaching to artificial feeding. Dr. Taaffe's observations lead him to the conclusion that the fatal summer diarrhoea of infants arises from improper feeding at a season when artificial foods are peculiarly apt to undergo change, particularly if great care and cleanliness are not observed; and when the intestinal canal is under the influence of high temperature, especially if at such time the atmosphere be polluted with the effluvia from defective sewers and accumulations of putrescent filth. Dr. Taaffe's report can scarcely fail to influence the action of the sanitary authority in this matter, and exercise a generally beneficial result upon the care of infants and young children in Brighton.

SCARLATINA CULTURE IN WHITECHAPEL.

A child died a few days ago of scarlet fever in Whitechapel. The registrar of deaths gave information to the sanitary authority, and thereupon the sanitary inspector, Mr. Skidmore Wrack, visited the house where the death had occurred. He found that it consisted of four rooms only, and was inhabited by two families. In the front room on the ground floor lay three children, suffering from scarlet fever, occupying it with the father and mother; in the back room lay the body of the dead child. The two upper rooms were occupied by a man, his wife, and five children, the children having been in attendance at a Board School during the whole period of sickness in the rooms below. But for the death of the child in the lower rooms nothing of this would have become known, and when it did become known such mischief as could have been done by the infected family had probably been done. The Board School being informed of the case excludes the children from the upper rooms, and so makes their infection tolerably sure by their retention at home, if it had not before occurred. The cultivation of scarlet fever under these circumstances is unavoidable, and the only chance the sanitary authority has of limiting the extension of the disease under such circumstances is by getting the earliest information of it. Pending general legislation on the subject, cannot the Metropolitan Sanitary Authorities follow the example of some of the great northern towns, and seek special legislation?

THE SMOKE NUISANCE.

A deputation of the Manchester Association for Controlling the Escape of Noxious Vapours from Manufactories recently had an interview with the Health Committee of the Salford Corporation, in order to urge upon them the adoption of more stringent measures for the suppression of the smoke nuisance. The Salford Committee deprecated any notion that the Corporation had been heedless in this matter, and flattered itself with the belief that the Salford atmosphere was "immeasurably" superior as to freedom from smoke to that of Sheffield, Leeds, Wolverhampton, Warrington, or Bolton. They could not hope to purify their atmosphere wholly of smoke, and in making matters too stringent for the suppression of smoke, they might incur a greater evil as affecting the welfare of the operatives. Indeed, better and more readily practicable methods of smoke-consumption must be waited for before all could be done towards suppression of the nuisance to the extent that was desirable. In short, the remarks of the committee remind us of an incident in a town not far distant from and as "smoky" as Salford. Not very long ago, standing on the hills above the town on a Sunday afternoon, and chancing to fall into conversation with an operative, we remarked on the pleasant aspect of the place without its customary pall of smoke. "Bonny enough," was the answer (we do not attempt to reproduce the dialect), "but, ah! my lad, if you had seen, as I have seen, more than once, this pretty prospect day after day, with no smoke from the long chimneys, and no food in the cupboard, but with wife and children on the hearth, you would not look on this pretty scene even on a Sunday afternoon without feeling a turn inwards."

Dr. Bridges has completed his inquiry into the disagreement between the medical officers of the St. George's-in-the-East Poor-law infirmary. The evidence will be submitted to the Local Government Board, with whom rests the decision as to the results and the determination of the measures to be taken, if any, to put an end to the state of things which led the Board of Guardians to invoke the Board's interference in the matter.

It has been resolved by the Epsom Rural Sanitary Authority that a fee of 2s. 6d. be paid to any medical practitioner in the district who shall first report (on a printed form provided for the purpose) to the inspector of nuisances the outbreak of certain infectious diseases in any part of the sanitary area. The Chertsey, Dorking, and Reigate unions, it appears, have already adopted a similar regulation with advantage.

A local paper states that of sixty-nine cases of "scarlet fever" reported to have occurred recently at Darwen, in Lancashire, one only, on an inquiry made by the medical officer of health, proved to be a case of that disease.

We are glad to observe the admirable way in which our contemporary, the *Graphic*, deals with the question of vaccination, and the suicidal folly of the anti-vaccinationists.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Under the influence of continued unseasonably mild weather English urban mortality showed a further decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4964 births and 2793 deaths were registered last week. The births were 221, and the deaths so many as 482, below the average weekly numbers during 1879. The deaths showed a further decline of 89 from the low and decreasing numbers in recent weeks; and the annual death-rate per 1000, which had been equal to 22.1, 20.6, and 20.1 in the three preceding weeks, further declined last week to 19.4, a lower rate than has prevailed in any week since the middle of July last. The lowest death-rates in the twenty towns last week were 13.0 in Wolverhampton, 14.6 in Norwich, 15.9 in Portsmouth, and 16.0 in Brighton. The rates in the other towns ranged upwards to 21.0 in Manchester, 21.1 in Liverpool, 23.7 in Plymouth, 24.6 in Sunderland, and 25.5 in Nottingham. During the past eleven weeks of the current quarter the death-rate in these twenty towns averaged only 21.6 per

1000, against 22.9 in the corresponding periods of the four years 1876-79.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 358 and 370 in the two preceding weeks, were 375 last week; they included 129 from scarlet fever, 74 from whooping-cough, 63 from measles, and only 32 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2.9 per 1000 in the twenty towns, and ranged from 0.7 both in Wolverhampton and Newcastle-upon-Tyne, to 3.8 and 4.5 in Hull and Sunderland. The 129 fatal cases of scarlet fever in the twenty towns, showed a further decline from recent weekly numbers; the largest proportional fatality occurred in Sunderland, Bristol, Manchester, and Bradford. Measles fatality was largest in Brighton and Salford, and that of whooping-cough in Nottingham, Hull, and Liverpool. The deaths from fever, principally enteric, which were 78 in the twenty towns in the second week of July, have since steadily declined, and were but 32 last week. Of the 19 deaths from diphtheria last week, 12 occurred in London, and 2 in Salford. Small-pox caused 33 more deaths in London, and one in Manchester; whereas no fatal case was returned in any of the eighteen other large towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 338 in the seven preceding weeks, further rose to 273 on Saturday last. The number of new cases of small-pox admitted to these hospitals, which had been 67 and 132 in the two previous weeks, fell again to 76 last week. The number of patients in the Highgate Small-pox Hospital were 26 on Saturday last, and 4 less than at the end of the previous week.

The deaths referred to diseases of the respiratory organs in London, which had been 334 and 295 in the two preceding weeks, were 307 last week, and were no less than 239 below the corrected average number in the corresponding week of the ten preceding years; 189 resulted from bronchitis, and 79 from pneumonia. The annual death-rate from lung diseases was equal to 4.4 per 1000 in London, and 4.9 in Liverpool.

In the twenty towns last week 67 uncertified causes of death were registered, equal to 2.4 per cent. of the total deaths. The proportion of uncertified deaths did not exceed 1.7 per cent. in London, whereas it averaged 3.0 per cent. in the nineteen provincial towns. No uncertified deaths were registered in eight of the twenty towns, whereas their proportion was largest in Wolverhampton, Bradford, Sheffield, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, the annual death-rate last week averaged only 19.9 per 1000, against 24.7, 22.1, and 21.7 in the three preceding weeks; this low rate exceeded, however, by 0.5 the still lower average rate in the twenty large English towns. The rates in the eight Scotch towns last week ranged from 15.4 and 19.1 in Dundee and Aberdeen, to 25.8 and 27.6 in Leith and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 112, 95, and 91 in the three preceding weeks, further declined to 80 last week. The annual death-rate from these seven diseases averaged 3.2 per 1000. In the eight Scotch towns the zymotic death-rate last week ranged from 1.0 in Dundee, to 4.2 and 6.2 in Paisley and Leith. The fatal cases of scarlet fever in the eight towns, which had declined in the five preceding weeks from 53 to 33, further fell to 17 last week, of which 9 occurred in Glasgow (corresponding with the number in the previous week) and 7 in Edinburgh and Leith. The 17 deaths referred to diphtheria included 10 in Glasgow and 4 in Edinburgh. The 13 deaths from whooping-cough corresponded with the number in the previous week. The 13 fatal cases of diarrhoea again showed an excess upon the average numbers for the season. The annual death-rate from lung diseases was equal to 4.9 per 1000 last week in the eight Scotch towns, against 3.9 in London; the highest death-rates from these diseases in the eight Scotch towns occurred in Leith, Paisley, and Greenock.

HEALTH OF DUBLIN.

The death-rate in Dublin showed a further decline last week. The annual death-rate from all causes within the city, which had declined from 39.6 to 27.2 in the five preceding weeks, further fell to 25.9 last week, a lower rate than has prevailed in the city in any week since the be-

Obituary.

FRANK BUCKLAND.

ginning of October, 1879. During the first eleven weeks of the current quarter the death-rate in the city averaged, however, 32.9 per 1000, against 21.0 in London, and 22.0 in Edinburgh. The 156 deaths in Dublin last week showed a further decline from recent weekly numbers, but included 24, or 15 per cent., which were referred to the seven principal zymotic diseases, or 6 more than those in the previous week; 11 resulted from scarlet fever, 7 from fever (including typhus, enteric, and simple), 3 from whooping-cough, 1 each from small-pox, measles, and diarrhoea, and not one from diphtheria. The annual death-rate from these seven zymotic diseases was equal to 4.0 per 1000 in Dublin last week, against 2.9 in London, and 2.7 in Edinburgh. The fatal cases of scarlet fever, which had been 7 and 6 in the two previous weeks, rose to 11 last week. The 7 deaths referred to fever showed a further decline from the excessive numbers in recent weeks, but were proportionally more than five times as numerous as the deaths from the same cause in the twenty large English towns. The 3 deaths from whooping-cough corresponded with the number in each of the two previous weeks. The deaths of infants differed but slightly from the numbers in the two previous weeks, while those of elderly persons showed a further decline.

THE SANITARY ASSURANCE ASSOCIATION.

A meeting of the members and subscribers of the Sanitary Assurance Association was held recently at the Langham Hotel, Sir Joseph Fayrer presiding, and Professor Tyndall taking part in the proceedings. A report of the proposed organisation of the Association was presented and adopted, and promises well for future success. One of the great advantages which the Association offers was aptly stated by Dr. Poore in the course of the meeting. Medical men, while often conscious that their patients are occupying houses which probably possess grave sanitary defects, are usually at a loss how to advise them to set about the discovery of these defects. The Association offers an easy and cheap way out of this difficulty. Persons may have recourse to it with confidence for a skilled examination and trustworthy report on their premises, and wise people will anticipate as far as practicable the need for the doctor by becoming permanent subscribers to the Association, and steadily availing themselves of the advantages it offers.

THE SERVICES.

TROOPS AT SHOEBOURNESS.

In the *Army and Navy Gazette* of the 11th inst. attention was called to the sanitary condition of Shoeburyness, which was described as "far from satisfactory. Typhoid fever is constantly occurring there, and is very prevalent in the neighbourhood." We have made particular inquiry into the matter, and find that, so far at least as the troops are concerned, this statement is quite erroneous. They are remarkably healthy, and not a single case of typhoid fever has occurred among them for a considerable period. Last year, in consequence of complaints regarding the quality of the water supplied to them, the War Office, on the recommendation of the Director-General, sanctioned the issue of spongy-iron filters to every barrack and quarter at the station, and this measure has been attended with the most satisfactory results, and the water is described as quite pure and good.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Joseph Johnston, M.D., has been granted retired pay, with the honorary rank of Brigade-Surgeon. Surgeon-Major William Snowdon Hedley, M.D., has retired upon temporary half-pay.

MADRAS MEDICAL ESTABLISHMENT.—To be Surgeon-Major: Surgeon Frederick Henry Blenkinsop.

MILITIA.—Surgeon Henry Steele, Forfar and Kincardine Artillery, resigns his commission.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the twenty-fifth session of this Society took place on Oct. 8th, 1880, when an address was delivered by Dr. Harry Knight Hitchcock, who was elected President in succession to Mr. J. P. Purvis, in which he gave a *résumé* of the advancement of medical science during the past year.

DEATH has removed from our midst, at a comparatively early age, one whom the public service can badly spare, and the loss of whom has excited deep and almost general regret. Frank Buckland died at 37, Albany Street, on the morning of the 19th inst., the victim of a chronic disease which, though it had lately incapacitated him from leaving his house, yet left his mind unaffected up to the last. He was born on December 17th, 1826, and was consequently only two days over fifty-four years of age. The son of the Very Reverend William Buckland, D.D., Dean of Westminster, well known in his day as a geologist and palæontologist, but whose fame is perhaps most closely associated with the valuable *Bridgewater Treatises*, young Buckland commenced his scholastic career at Winchester School, and terminated it at Christ Church, Oxford. Selecting medicine as a career, he studied in London and Paris; and having graduated he served the office of House Surgeon at St. George's Hospital for some time. A commission having been offered him in the Household Cavalry, he joined the 2nd Life Guards in 1854 and served in the regiment as Assistant Surgeon until 1863. Whatever fancy he may have had for his profession when he first entered it, it soon became evident that his bent was zoology, or rather what is called natural history. He was fond of keeping all kinds of animals, rare or common, and even while in the Life Guards his barrack-room was often more like a miniature menagerie than the *sanctum* of a Guardsman. This characteristic he had certainly exhibited from his earliest days, but it was all-absorbing as he reached middle life, and perhaps no more keen observer of animal life or student of animal nature has been known in our days. Between him and animals and birds there almost immediately sprang up the closest intimacy, if not sympathy, and there were few creatures he could not make a companion of, more frequently an attached friend, after one or two interviews. We need not wonder that the *Field* at an early period received many communications on natural history from him, and when he left the Guards he was, if not on the staff, at least a regular contributor. *Land and Water* was started, in conjunction with a great authority on piscatorial matters, Mr. Pennell, in 1866, and it was in this periodical that he recorded all his current observations on matters connected with natural history, particularly in its practical aspect, and gave information as to sea and river fisheries. Many curious and valuable facts are recorded here, for Buckland collected material from every source, and nothing in the way of a new species or new variety, an unusual or unknown habit, or monstrosity or freak of nature of any kind, ever came amiss to him. Pisciculture, however, may be said to have been his speciality, and he had already made himself a name in connexion with it when, in 1867, the Government made him Inspector of English Salmon Fisheries, and in 1870 the trust was extended when he was appointed Special Commissioner for the Salmon Fisheries of Scotland. In this office his intimate knowledge of fish habits and fish-breeding served him and the country well, and if anyone cares to know what he has done in the way of improving the quantity and quality of various kinds of freshwater fish, increasing the supply of sea fish, introducing trout and salmon into new rivers of new countries, protecting fish from waste and unnecessary destruction, he has only to refer to the many Blue Books which contain his reports, and the reports of commissions of which he was a member. His indomitable exertion and enthusiasm led him to accomplish more in developing the resources of our rivers and seas than any other man had ever done, and his system of fish culture is so excellent that it has been adopted very largely in other countries. In this way he was a most excellent public servant, and to him the country is greatly indebted.

So long ago as 1857, he published four series of "Curiosities of Natural History," volumes teeming with strange and curious facts about many kinds of animals; in 1873 a "Familiar History of Fishes" appeared; and the "Logbook of a Fisherman and Zoologist" in 1876. Last year he edited a splendid edition of Gilbert White's perennial "Natural History of Selborne." In all these, as well as in his other writings, we find natural history treated in the most simple

and yet most attractive and instructive manner. Indeed, few can deny that Frank Buckland has done very much to popularise natural history and place it before us in its most fascinating aspect. There are none of his writings which are beyond the depth of comprehension of an average school-boy, and yet they contain great scientific truths.

Frank Buckland possessed many of his father's characteristics, and these are discerned in his writings. More especially did he inherit that genial humour and hearty appreciation of a joke which sometimes made the worthy Dean the subject of an anecdote. Vigorous in body, and original to a large extent in mind, he worked incessantly—physically and mentally. His collection at the South Kensington Museum is an example of the skill—artistic and scientific—he brought to his loved pursuit, and the patience and enthusiasm with which he was endowed. His intellect was quite clear and unclouded up to death, and he had been actively interesting himself in promoting a piscatorial show at Grimsby, and in getting up prizes for the fishermen—a class of men with whom he was most deservedly popular, and whose hard and dangerous occupation he did his utmost to ameliorate and brighten. His name will long remain green in the memories of those who knew him, as that of a good-hearted man, and a true public servant and benefactor.

Medical News.

UNIVERSITY OF LONDON.—The following candidate has passed the recent Examination in subjects relating to Public Health:—

Giles, George Michael James, St. Mary's Hospital.

UNIVERSITY OF CAMBRIDGE.—The following have passed the First Examination for the degree of M.B.:—

CLASS I.—None.

CLASS II.—Agar, B.A., Caius; Barker, Trinity; Barton, Caius; Beard, non-collegiate; Bisshopp, non-collegiate; Blaker, non-collegiate; Castle, Pembroke; Challenor, B.A., non-collegiate; Clarke, Caius; Dumbleton, St. Peter's; Dumergne, Corpus; Floyer, B.A., King's; Hinnell, Pembroke; Love, St. John's; Marshal, Clare; Nichol, Caius; Pash, B.A., Pembroke; Preston, Corpus; Raven, Emmanuel; Sidebotham, Caius; Smart, Caius; Smith, Caius; Spriggs, Caius; Stickler, Clare; Taylor, B.A., St. Peter's; Thurtell, B.A., Caius; Watts, Corpus; Wishaw, non-collegiate; Wilson, Caius.

The following have passed the Second Examination for the M.B. degree:—

CLASS I.—Sherrington, Caius.

CLASS II.—Aldred, B.A., Caius; Bostock, B.A., Pembroke; Brinton, Downing; Dill, B.A., Caius; Fowler, B.A., Caius; Griffiths, M.A., Trinity; H. Groom, B.A., Magdalene; Hewitt, B.A., Christ's; Knowling, B.A., King's; Morris, B.A., Caius; Owen, B.A., non-collegiate; Peskett, B.A., Downing; Pollard, B.A., Caius; Richardson, B.A., King's; Slater, B.A., St. John's; Spicer, B.A., Caius.

The following have passed the second part of the Third Examination for the degree of M.B.:—

CLASS I.—Alister, M.A., St. John's; Mackern, Caius; Phillips, B.A., St. John's.

CLASS II.—Bentham, B.A., Pembroke; Brunton, B.A., St. John's; Clark, B.A., Christ's; Collier, B.A., Jesus; Gripper, B.A., St. John's; Jessop, B.A., Caius; Nichols, B.A., St. Catherine's; Weldon, B.A., Caius.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Dec. 16th:—

Bathe, Anthony John, Southampton.
Farrer, Robert Thompson, Brighouse, Yorkshire.
Galpin, George Luck, Grahamstown, Cape of Good Hope.
Garman, John Cornelius, Plumstead.
Norville, Frederic Harvey, Royal Infirmary, Bristol.
Wilson, George John, Western-road, Brixton.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Richard Hingston, London Hospital; Thomas Horsfall, Leeds School of Medicine; George Leonard Webster, King's College.

COLLEGE OF PHYSICIANS IN IRELAND.—At examinations held in December the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Francis E. Ackerley, Joseph Boyd, Robt. Joseph Browne, Arthur Wellesley Cadman, Edmund Corcoran, Wm. Joseph Fottrell, Edw. T. Geoghegan, Jas. Foulds Joseph, Richard Francis O'Brien, Janet Monteath Rushbrook, William Augustus West, Geo. Herbert Withington.

MIDWIFERY.—Francis E. Ackerley, Joseph Boyd, Robert Joseph Browne, William Joseph Fottrell, Edw. Thomas Geoghegan, Joseph Patrick Kealy, Richd. Francis O'Brien, Janet Monteath Rushbrook, William Augustus West.

The undermentioned Licentiates have been admitted Members:—

Robert Bradshaw, David John Browne, Mark Anthony Harte, John D. Hillis, Henry Lowndes, William Kildare Miley, George Jonathan Mitchinson, Thomas Tarrant (Brigade Surgeon, A.M.D.).

UNIVERSITY OF DUBLIN.—The following degrees were conferred in the Examination Hall, Trinity College, on the 15th inst.:—

BACHELOR IN MEDICINE.—Arthur Cockle, Stuart Davis, John Galbraith, John Mason, John Charles Martin, John Michael Nicolls, George Patterson, George Scriven.

BACHELOR IN SURGERY.—Henry Lewis Clare, Stuart Davis, William Spear Gordon, John Charles Martin, John Michael Nicolls.

MASTER IN SURGERY.—William Cox Nevill.

DOCTOR IN MEDICINE.—George A. Bluett, Francis Charles McNalty, William Cox Nevill.

LICENTIATE IN MEDICINE.—William Smyth.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

By the will of the late Sir Francis Lycett the Brompton Hospital for Consumption receives £500, St. Mary's Hospital £100, the Royal Free £200, the Cancer Hospital, Brompton, £200, the Royal Hospital for Incurables £300, King's Cross Hospital £500, the Truss Society £100, and the Victoria Park Hospital for Diseases of the Chest £500. Miss Matilda Cohen bequeathed £100 to the Brompton Hospital and to the Hospital for Incurables, Putney, and £50 each to the Sea-bathing Infirmary, Margate, and the Royal Victoria Hospital for Sick Children. "C. M. F." has given £100, Gervase Taylor £50, "Anonymous" £50, and "H." £50 towards the funds of the Adelaide Hospital, Dublin.

CAMBRIDGE AND EPSOM.—The Shuttleworth Scholarship of £60, tenable for three years, open to all registered students of the University, has been recently awarded to Mr. G. Bernard Hoffmeister, already a Natural Science Scholar (£60 a year) of Caius, youngest son of Dr. Hoffmeister of Cowes. Mr. Hoffmeister was also First Prizeman in Science in each of his three years of residence, and previously held the Forest and Gilchrist Scholarships, £50 each, for three years from Epsom College, the latter carrying with it a Free Medical Scholarship to St. Bartholomew's Hospital. In the Natural Science Tripos list, issued on the 18th inst., Mr. Hoffmeister's name appears in the First Class, and as distinguished in Botany.

OWENS COLLEGE.—At a meeting of the Council held at the College on the 17th inst. the following members of the medical profession were, on the recommendation of the Senate, elected to the associateship of the College:—Samuel Buckley, M.B. London, 1880, F.R.C.S. Eng., 1873; John James Kent Fairclough M.D. Queen's University, Ireland, 1877; John Thomas Faulkner, M.B. London, 1880; Thomas Hahnemann Hayle, M.B. London, 1876; John William Meek, M.B. London, 1880. A Platt Physiological Exhibition, of the value of £20, was awarded to Mr. Walter Hurst.

We understand (says the "Herald and Weekly Free Press") that Dr. Forbes of Milbourn has just endowed the Inverness Dispensary with £6000. This endowment will be under the management of trustees. The medical officer, who may be one of the practitioners of the burgh, will receive £100 of the interest of the fund, whilst £20 will be added to the salary of the superintendent, the rest of the endowment being devoted to the purchase of medicines and to meet the general expenses of the institution. The present medical attendant is Mr. F. M. Mackenzie.

THE LATE ROBERT HARKNESS, F.R.S.—During last summer a costly memorial window was placed in the Examination Hall of the Queen's College, Cork, to the memory of Professor Harkness. The deceased gentleman, who was a distinguished geologist, died in 1878, and formerly held the Professorship of Geology in the Queen's College, Cork, and latterly also of Natural History.

In consequence of the recent fatal football accident in Southampton, the Mayor of that town has issued a notice prohibiting the pastime on the public lands as long as it is played according to the Association or Rugby rules, and he calls on the heads of families and schools to support him in his endeavour to modify the practice of the game.

THE Bazaar and Fancy Fair held last week on three several days, at the Ulster Hall, Belfast, for the benefit of the Belfast Royal Hospital, has, we understand, fully realised what was anticipated; and a very large amount will be added to the funds of this charity.

PROFESSOR DEWAR will give the first of his Christmas Lectures (adapted to a juvenile audience) on Atoms, on Tuesday next, Dec. 28th, at three o'clock, at the Royal Institution.

MR. W. J. FULLER, resident surgeon of the St. Marylebone Workhouse, will be granted a superannuation allowance of £80 a year on resigning his appointment.

THE Lord Mayor of London has consented to perform the ceremony of opening the new Temperance Hospital buildings in the Hampstead-road, on Friday, March 4th.

DR. O'SULLIVAN has been elected Mayor of Limerick for 1881.

CONTRIBUTORS TO THE LANCET FOR 1881. SUPPLEMENTAL LIST.

ALEXANDER, WILLIAM, Surgeon-Major, M.D., Queen's Univ., Irel., Military Station Hospital, Bradford.

BROWN, A. GARDINER, F.R.C.S. Edin., Aural Surgeon to the London Hospital.

CHRISTIE, J., M.D. (Glas.), Lecturer on Hygiene and Public Health at Anderson's College; Medical Officer of Health, Hillhead; Dispensing Surgeon to Western Infirmary, Glasgow.

CHURCHILL, F., M.D. Edin., Surgeon to the Victoria Hospital for Children; Honorary Surgeon to the Young Women's Home, Sloane-street, London.

COOKSON, S., M.D. St. And., Medical Officer and Public Vaccinator, Castle Church District, Stafford Union.

DAVIES, N. E., L.R.C.P. Lond., M.R.C.S. Eng., Hon. Physician and Surgeon, Yeatman Hospital, Sherborne.

DOWN, J. L. H., M.D. Lond., Physician to the London Hospital.

DUKE, ALLEN, M.D. St. And., Surgeon to the Dover Hospital and Chichester Infirmary.

DUNLOP, A., M.D. Edin., Honorary Medical Officer to the Jersey General Dispensary.

DUNLOP, W. M., M.B. Glas., Resident Medical Officer to the St. Pancras Workhouse, King's-road, N.W.

GILES, P. B., Jun., L.R.C.P. Edin., M.R.C.S. Eng., Medical Officer of Health, Hay Rural District.

GREENWAY, H., M.R.C.S. Eng., Medical Officer of Health, Plymouth Borough; Consulting Ophthalmic Surgeon to Plymouth Provident Dispensary.

HARRIS, V. D., M.D. Lond., Consulting Physician and Demonstrator of Physiology to St. Bartholomew's Hospital; Assistant Physician to Victoria-park Hospital.

JACKSON, T. V., M.R.C.S., Senior Surgeon at Wolverhampton and Staffordshire General Hospital.

JOHNSON, R. LOCKE, L.R.C.P., L.R.C.S. Edin., Physician to North London Consumption Hospital; Physician to St. John's Hospital for Skin Diseases, Leicester-square.

KEIR, W. INGRAM, L.R.C.P., L.R.C.S. Edin., Medical Officer of Health, Rural Sanitary Authority, and Surgeon to Cottage Hospital, Melksham.

LUSH, W. J. H., M.D., F.R.C.P. Ed., M.R.C.S., F.L.S., Hon. Visiting Medical Officer to the Andover Cottage Hospital, Associate (late Warneford scholar), King's College, London.

MAY, E. HOOPER, M.D. St. And., F.R.C.S. Eng., Surgeon to the General Dispensary and to the Training Hospital, Tottenham.

MEREDITH, W. A., M.B. Edin., M.R.C.S. Eng., Surgeon to the Samaritan Free Hospital for Women and Children, and Anaesthetist to Seymour-street Branch.

O'CONNOR, B., M.D., M.R.C.P. Lond., Physician to the Westminster General Dispensary, Gerrard-street, W.

PATON, J., M.B. Glas., Surgeon to the Greenock Hospital.

PHILLIPS, E. E., L.R.C.P. Edin., M.R.C.S. Eng., Medical Officer of Health, South-end Urban District, and Rochford Rural District.

PRIDEAUX, ENGLEDEU, L.R.C.P. Lond., M.R.C.S. Eng., Medical Officer to the District and Union House of Wellington.

RIVINGTON, W., M.B., F.R.C.S. Eng., Surgeon, London Hospital, Lecturer on Human Anatomy to London Hospital Medical College.

ROSS, R., M.D. St. And., Physician to Belfast Royal Hospital.

STOKER, W., F.R.C.S. Eng., Senior-Surgeon, Durham County Hospital.

TROUP, R. W., Surgeon-Major, M.B. Aberd., Canterbury.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ALTHAM, J., M.B., has been appointed House-Surgeon to the Royal Surrey County Hospital, Guildford.

BATTLE, W. H., F.R.C.S., has been appointed Surgical Registrar to St. Thomas's Hospital Medical School for 1881, vice H. P. Porter, F.R.C.S., whose appointment has expired.

CLARKE, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Third District of the Hailsham Union.

DINGLE, W. A., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Houseless Poor Asylum, St. Luke's.

EMMERSON, W. L., M.D., has been appointed Public Analyst for the Borough of Stamford for one year.

FRASER, D. A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for Burnham, Somersetshire, vice Moore, resigned.

GALBRAITH, W., L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Medical Officer of Health for the South Gooforth Urban Sanitary District.

GORDON, J. A., L.R.C.P. Ed., L.R.C.S. Ed., has been appointed Medical Officer to the Ludham District of the Smallburgh Union.

GROOME, W. W., M.B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the First District and the Workhouse of the Stow Union.

HALL, J. G., M.B., C.M., has been appointed Fourth Surgeon to the Aberdeen Royal Infirmary and Lunatic Asylum.

HAMILTON, G. S., L.R.C.P., L.R.C.S. Ed., has been appointed Assistant House-Surgeon to the Liverpool Northern Hospital, vice C. Shears, L.R.C.P.L., promoted.

JACKSON, G. J., M.R.C.S.E., has been appointed Visiting Surgeon to the London Diocesan Deaconess Institution, Tavistock-crescent, W., vice G. Hastings, M.D., resigned.

JAMES, W. D., M.R.C.S.E., has been appointed an Honorary Surgeon to the Sheffield Public Hospital for Skin Diseases.

JONES, R., M.B. &c., has been appointed Assistant Medical Officer to the Earlswood Asylum, Surrey, vice Spence, M.D., resigned.

KNOX, T., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Workhouse of the Maguiresbridge District of the Lisnaskea Union.

MARTIN, J. W., M.D., has been appointed Honorary Physician to the Sheffield Public Hospital for Skin Diseases, vice G. H. De Wolfe, M.D., resigned.

OLIPHANT, J., M.D., has been appointed Public Vaccinator to the Western District of the Leicester Union.

PRINCE, F. T., M.R.C.S.E., has been appointed Surgeon to the St. George, Hanover-square, Provident Dispensary, vice J. H. Morgan, F.R.C.S., resigned.

ROOME, H. A., M.B., C.M., has been appointed Honorary Assistant Medical Officer to the Royal Surrey County Hospital.

ROSS, Mr. T., has been appointed Assistant to the Extra Physicians of the Royal Hospital for Sick Children, Edinburgh.

SHEARS, C. H. B., L.R.C.P.L., M.R.C.S.E., has been appointed House-Physician to the Liverpool Northern Hospital, vice D. M. Fraser, M.B., resigned.

SMALE, M., M.R.C.S.E., L.S.A.L., L.D.S.E., has been appointed Medical Tutor to the Dental Hospital of London, Leicester-square.

STOKES, H. F., L.R.C.P.L., M.R.C.S.E., has been appointed Registrar and Chloroformist to the Evelina Hospital for Sick Children.

SYKES, W. J., M.D., has been appointed Medical Officer of Health for the Portsmouth Urban Sanitary District, vice Turner, resigned. Also Public Analyst for the same District.

TAYLOR, Mr. T. P., has been appointed House-Surgeon to the Essex and Colchester Hospital, vice Wells, resigned.

THOMSON, W. S., M.D., C.M., L.F.P.S.G., has been appointed Medical Officer of Health for the Peterborough Urban Sanitary District.

WILLIAMSON, G. E., F.R.C.S.E., has been appointed Assistant-Surgeon to the Newcastle-on-Tyne Infirmary.

Births, Marriages, and Deaths.

BIRTHS.

HEELAS.—On the 14th inst., at Ersking Lodge, Primrose-hill-road, N.W., the wife of James Heelas, M.D., of a daughter.

RYAN.—On the 4th October, at Gympie, Queensland, the wife of John Pennefather Ryan, L.K.Q.C.P.I., L.R.C.S.I., of a son.

WOLSTON.—On the 19th inst., at 46, Charlotte-square, Edinburgh, the wife of Walter T. P. Wolston, M.D., of a son (stillborn).

MARRIAGES.

BROOKE—LIGHTBOWN.—On the 18th inst., at the Pendleton Congregational Church, Manchester, by the Rev. E. Walker, Henry A. G. Brooke, M.B., B.A., to Sara, fourth daughter of Henry Lightbown, J.P., of The Willows, Weaste.

CULLING—TOWNSEND.—On the 23rd inst., by licence, at St. Mary's, Ealing, Middlesex, William Robert, L.S.A.L., eldest son of the late Robert Culling, Surgeon, of West Lydiard, near Somerton, Somerset, to Jessie, third daughter of the late Arthur Townsend, Esq., of the County of Essex.

FOWLER—WATSON.—On the 18th inst., at St. James's, Piccadilly, by the Rev. J. Dyer Tovey, M.A., Robert Fowler, M.D., of 12, Old Burlington-street, W., and of Bishopsgate, E.C., to Judith, second daughter of the late John Watson, formerly of Rosenheim, West-hill, Putney-beath, and 74, Lower Thames-street. No cards.

STACPOOLE—McBAIN.—At Cromwell, Otago, New Zealand, by the Rev. B. Drake, Charles A. Stacpoole, Surgeon, to Joanna, youngest daughter of the late John McBain, of Melbourne.

DEATHS.

- DITCHETT.—On the 16th inst., at his residence, Ugate, Louth, Lincolnshire, W. D. Ditchett, J.P., M.R.C.S.E., in his 75th year.
- MILLER.—On the 10th inst., at Newport, Isle of Wight, Margaret Booth, the beloved wife of C. M. Miller, M.D., of Shire House, Sheffield, Medical Officer of Health for Carisbrooke.
- PUGHE.—At his residence, Catharine-street, J. E. Howard Pughe, M.R.C.S.E., son of the late Mr. J. Pughe, J.P., of Aberdovey, aged 35.
- ROE.—In March last, at Cape Coast Castle, Charles Roe, L.R.C.S.I., aged 25.
- WEBB.—On the 5th inst., from enteric fever, at Shrewsbury, John Rheece Wynn Webb, F.R.C.S.E., L.R.C.P.L., of Coln, St. Aldwyn's, Gloucestershire, aged 25.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INTERNATIONAL MEDICAL CONGRESS.

LONDON, 1881.

SECTION VIII.—MENTAL DISEASES.

Dr. LOCKHART ROBERTSON, President.

Dr. CRICHTON BROWNE, LL.D., F.R.S.E., } Vice-Presidents.
Dr. MAUDSLEY,Dr. GASQUET, } Secretaries.
Dr. SAVAGE,

Proposed List of Subjects for Discussion, subject to revision before
31st December, 1880.

ANATOMY.—1. Modes of Preparation of Nervous Tissue. 2. Morbid Appearances due to Modes of Preparation. 3. Minute Structure of Special Parts of Brain.

PHYSIOLOGY.—1. Relation of Cerebral Localisation to Mental Symptoms as Hallucinations. 2. Hypnotism.

PATHOLOGY.—1. Of Idiocy, Morphological and Histological Changes. 2. Relations of Insanity to Gout, Renal Disease, Exophthalmic Goitre, and to Coarse Brain Disease.

CLINICAL.—1. "Folie à double Forme." 2. Influence of Intercurrent Diseases on Insanity. 3. Insanity due to Toxic Agents.

THERAPEUTICAL.—1. Use of Baths, of Narcotics, of Chloral Hydrate, of Opium, and of Alcohol. 2. New and Unusual Remedies.

ASYLUM ADMINISTRATION.—1. Cottage and Village Treatment. 2. New Legal Codes. Austrian, Italian, English Projects.

CIVIL RELATIONS OF THE INSANE.—1. Marriage, Wills. 2. Insanity and Aphasia.

CRIMINAL RELATIONS OF THE INSANE.—Special Asylums for Insane Criminals.

LONDON, AUGUST 2ND TO 9TH, 1881.

SECTION III.—PATHOLOGY AND MORBID ANATOMY.

Dr. SAMUEL WILKS, F.R.S., President.

Dr. BRISTOWE, } Vice-Presidents.
JONATHAN HUTCHINSON, Esq.,
Prof. SANDERS, M.D., F.R.S.E., Edinburgh,Dr. PAYNE, } Secretaries.
MARCUS BECK, Esq., M.S.,

The following subjects are those proposed for discussion:—

I.—The relations of minute organisms to certain specific diseases, such as Relapsing Fever, Ague, and Malignant Pustule (Anthrax).

II.—The relations of minute organisms to unhealthy processes arising in Wounds, and to Inflammation in general.

III.—Tubercle: 1. Its histological characters. 2. Its relation to inflammatory processes in different organs, such as the Lungs, Lymphatic Glands, Bones, and Joints.

IV.—The origin of Cancer and Sarcoma, and their relation to the Normal Tissues in which they arise.

V.—Diseases of the Kidneys: 1. The morbid histology of the different forms of Bright's Disease. 2. The relation of Renal Disease to disturbances of the general circulation, and to alterations in the Heart and Bloodvessels.

VI.—Recent Researches in the Morbid Anatomy of the Brain and Spinal Cord.

It is proposed to hold exhibitions of microscopical specimens in illustration of each of these subjects, and, further, to afford opportunities for the demonstration of methods and instruments of research, in any of those in which it would be desirable.

In thus selecting certain special subjects for discussion, it is by no means intended to exclude from consideration other pathological topics.

All communications relating to this Section should be addressed to one of the Secretaries, whose addresses are given below, and abstracts of all papers intended to be read at the Congress should be sent in by April 30th, 1881, to be submitted for approval to the Executive Committee, and to be translated into German, French, or English.

JOSEPH FRANK PAYNE, M.D., } Secretaries.

MARCUS BECK, }
30, Wimpole-street, London, W., }

THE LANCET IN 1880.

At the commencement of the year 1880 THE LANCET was permanently enlarged from 72 to 80 pages. Notwithstanding this increase of space, it has been necessary to give an average of more than THREE EXTRA pages each week during the year. The tale of our work, as shown by the GENERAL INDEX, which appears in the present number, now stands as follows:—We have devoted 2080 pages to the medical subjects of the year, giving 238 to the publication of clinical lectures, 351 to original articles by practising members of the profession, 97 to reports of hospital cases, 54 to reviews, and 401 pages to the Editorial discussion of matters of professional interest. Meanwhile the steadily and rapidly increasing demands on our public space have compelled us to appropriate 2252 pages to the use of advertisers. The projected increase of the year has been more than justified by the claims made upon THE LANCET as a medical newspaper. Some notion of the part this Journal has now assumed in the periodical literature of the profession may be gathered from the fact that during the year now closing we have printed no less than 676 letters from medical men, giving an average of THIRTEEN in each number. Some of our issues have contained upwards of a thousand advertisements, and it has been difficult to keep this section of the Journal within the limits thus indicated. One of the prominent features of our Editorial work during the year has been the development of an extended, and, as we believe, very efficient organisation for the notice of matters affecting the Public Health both at home and abroad. Medical Officers of Health and Sanitarians generally now find in THE LANCET an admirable section devoted to Sanitary Science, and a thoroughly effective channel for information and the publication of special news. Advertisers who have so signally shown their appreciation of the facilities offered by THE LANCET during the last year have been furnished with a special INDEX OF ADVERTISEMENTS, which has proved of great value both to those who announce their wares and wants and to those who seek the information advertisements supply. In the past year we have increased the size of particular numbers of the Journal as occasion required. For example, on the 8th of May and the 11th of September we issued numbers comprising ONE HUNDRED AND FOUR PAGES each. We shall pursue the same policy in 1881 which has been so successful in 1880, and, with a constantly growing circulation, we confidently hope to maintain the high position which the late Mr. Wakley, the founder of this Journal, claimed and asserted, for the trust we have received from his hands.

Notes, Short Comments, and Answers to Correspondents.

One Aggrieved.—The recent Royal Warrant removed some of the grievances which, however much our correspondent may now decry them, were put prominently forward by the officers of the department. The Marquis of Ripon has promised an inquiry into the other causes of discontent which were brought under his consideration, and, pending that inquiry, we do not think the publication of our correspondent's remarks would tend to promote the interests of the service.

Mr. A. Morris.—It is possible to obtain clinical instruction in mental diseases at most of the public asylums; and in connexion with each school of medicine there is a lecturer on Psychological Medicine who provides the teaching required.

Læsus.—Could our correspondent favour us with another letter, and it shall receive attention?

A Bart's Student.—We are strongly of opinion that no one who is not a medical man should practise dentistry, the L.D.S. notwithstanding.

Mr. E. M. Holmes is thanked.

*Enquirens, M.D., (Leeds).—*1. To a limited extent only. The water should be boiled immediately before using, and under no circumstances should more than the quantity required for a day's consumption be boiled at one time. Of course, except under circumstances where a pure water-supply can by no possibility be obtained, the use of water containing sewage would not be assented to by a medical man.—2. Fish contains a good deal of phosphorus; but, as a feeder of nerve-tissue, we hold it far inferior to butchers' meat.
Mr. M'Gill's paper will appear in an early number.

"NOTES ON THE PATHOLOGY OF DIABETIC URINE."

To the Editor of THE LANCET.

SIR,—Having read Dr. Cameron's Pathological Notes on Diabetic Urine in your impression of Nov. 18th, I beg leave to send you the following report of two specimens of urine, with some comments upon them, in the hope that they may be of interest:—

SPECIMEN 1.—Urine reddish-yellow, slightly turbid; slight flocculent deposit; specific gravity 1007; reaction acid. Contains sugar, and about one-fifth column of albumen. Microscopic examination shows numerous large granular casts, leucocytes, and squamous cells. Quantity of sugar, twenty-four grains per ounce.

SPECIMEN 2.—Urine yellow, turbid, thickish deposit; specific gravity 1009; reaction faintly acid. Contains about one-fourth column of albumen; no sugar.

Remarks.—Specimen 2 was the urine of a traveller, a gentleman who was known to be suffering from diabetes and albuminuria. Being under the impression that the sugar could not have disappeared entirely from his urine, I persevered, with every precaution necessary, to overcome the numerous fallacies generally met with in testing for glucose. Both Fehling's and Trommer's tests failed to reduce the copper, even when the test-tube was kept in hot water for some time, and even after having stood cooling some hours. With Moore's test, after several minutes' boiling, the colour of the urine was only considerably increased. Not having been successful in the reduction of copper, I endeavoured to reduce trisnitrate of bismuth in carbonate-of-soda solution; but although only a very small quantity was used, the colour of the metal was not altered in the slightest degree. Imagining, therefore, that the reason of these tests not effecting the reduction of the metals must be owing to the sugar being present in very small quantities, and the other constituents approximating their normal standard, I resolved to try Seegen's test, whereby the urea, uric acid, &c., are removed from the urine by repeatedly filtering it through charcoal. This was followed by precisely the same results as the former experiments. An attempt was made to precipitate the uric acid by nitric acid, and after standing some time I filtered the precipitated albumen and uric acid, and applied Trommer's test to the filtrate. A few drops of the solution of copper were first added, and then liquor potassæ until the liquid was only faintly acid or neutral; then on applying heat for a short time, the red deposit which characterises sugar became apparent. Is this owing to the fact, as Dr. Schunck announced in the *Philosophical Magazine* (March, 1862), that healthy urine when boiled with acids gradually deposits a resinous substance, which acquires the power of reducing the oxide of copper? Or has the glucose been replaced by a substance called inosite, which is not capable of reducing copper, bismuth, or silver in an alkaline solution, and which is found in cases of diabetes and Bright's disease?

I thought these two specimens interesting, in addition to the above, as regards the low specific gravities. I suppose it is entirely depending upon the albumen being present, as in neither of the cases was water taken or passed in excessive quantities.—Yours obediently,

Birmingham, Nov. 1880.

AUGUSTUS F. CLAY.

"SEAWEED AS A SUBSTITUTE FOR JAM."

In reference to his note which appeared in our issue last week, *Mr. G. C. Karop* writes that he meant to say it is *not* the diatom, *Arachnoidiscus japonicus*, but the seaweed on which it grows, that is used for making jelly.

Mr. G. E. Carre.—The announcement appears on p. 998 of our last issue.

THE DISCUSSION ON "LISTERIAN OVARIOTOMY."

To the Editor of THE LANCET.

SIR,—There are several inaccuracies in the otherwise admirable report of the meeting of the Medico-Chirurgical Society, published in your last issue, that I should like to correct. The first occurs in the following: "He had not once to use the ice-cap in cases treated with this solution (one per cent.), and out of 29 cases had lost eight, two deaths being from shock." It should have been: "He had not once to use the ice-cap in the last 29 cases, and out of seventy-eight modified Listerian cases had lost eight," thus giving a mortality of 10·2 per cent., or, excluding the two deaths from shock, a mortality of only 7·8 per cent. The second consists in the substitution of Mr. Heath's name for that of Dr. Keith. The third was an error on my part—viz., in the reference to the statistics collected by Peruzzi. In the second hundred the proportions were the reverse of those of the first hundred—a result which Peruzzi attributes to the combined effects of Listerism and drainage. Yet as evidence that Listerism alone could not be said to have done very much for ovariectomy in Italy, which was my argument, there still appears a mortality of over 33 per cent., with this interesting fact, that in addition to septicæmia appearing several times in the list of deaths, we have a new cause figuring there—viz., that of carbolic poisoning.

Yours faithfully,

Granville-place, Dec. 20th, 1880.

GEO. GRANVILLE BANTOCK.

DR. BARRY'S REPORTS.

WE are requested to state that Dr. Barry's Reports, which we noticed in our impression of Dec. 4th, are published by Mr. Nettle, of Settle. *Mr. Thomas Bell, (Uppingham).*—We cannot give a decisive reply until we see the MS.

Dr. Prior.—The paper is marked for insertion.

ON THE ASSOCIATION OF AFFECTIONS OF THE THROAT WITH ACUTE RHEUMATISM.

To the Editor of THE LANCET.

SIR,—I beg the favour of an opportunity to draw attention to the fact that, however lightly treated in text-books of general medicine, the connexion between tonsillar inflammations and the gouto-rheumatic diathesis has been insisted on by me, as many can testify, for upwards of ten years, and is dwelt upon at full length in my work on "The Throat and its Diseases," published in March, 1878.

Since this point was referred to by very many of my reviewers as novel, at least as to the extent that I carried the similarity of causes, symptoms, progress, and treatment of the two affections, I may assume that there was some originality in the suggestion, and that if so, I may lay claim to any credit attaching to its first publication. The fact that my book did not receive the honour of a review in your pages, perhaps justifies Dr. Fowler in thinking that he is breaking new ground in publishing his very interesting list of corroborative cases. For the same reason I claim a prominent place in your columns for this short statement of my position.

I would add that in my experience patients subject to tonsillitis are not often the victims of muscular or articular manifestations of the disease, provided the throat affection be treated by an eliminative, not by an abortive process. I therefore always commence treatment by an active purge, and combine sulphate of magnesia and potash salts with the salicylate of soda. Finally, in those few cases in which the rheumatic connexion is not clearly to be traced, and tonsillar inflammation is frequently recurring, an insanitary condition of dwelling-house, food, or vocation is generally at the root of the mischief.

Your obedient servant,

Weymouth-street, W., Dec. 1880.

LENNOX BROWNE.

Dr. W. R. Smith, (Cheltenham).—The paper will appear as early as our arrangements will permit.

Mr. Freeman.—Thanks.

THE demands of the Summary and the Index will be a sufficient explanation to our readers of the postponement of notice of many subjects.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Sturges, London; Professor Rutherford, Edinburgh; Dr. Smart, Dowlais; Dr. N. Harris, London; Dr. Keir, Melksham; Mr. Kesteven, London; Dr. Foster, Leeds; Mr. Story, Linslade; Mr. Giles, jun., Staunton; Mr. Freeman; Mr. Hodges, Leicester; Dr. Savage, Birmingham; Dr. Dunlop, London; Mr. Treves, London; Mr. Stoker, Durham; Mr. Partridge, London; Mr. Rivington, London; Dr. Taylor, Liverpool; Mr. Bell, Uppingham; Dr. Hinds; Mr. Phillips, Southend; Dr. G. W. Balfour; Mr. Jones, Lewes; Dr. Lownds, Egham; Mr. Reeves, London; Mr. Christy, London; Mr. Cookson, Stafford; Dr. Marshall, Conishead Priory; Mr. Cable, Greenwich; Mr. Paton, Greenock; Mr. Jackson, Wolverhampton; Dr. Christie, Glasgow; Dr. Dunlop, Jersey; Mr. Hooper, Newhall; Dr. Latham, Cambridge; Mr. Napper, Cranleigh; Mr. May, Tottenham; Dr. L. Down, London; Mr. Meredith, London; Mr. J. Mahomed, London; Mr. H. M. Ellis, Eastney; Dr. Waller, Edinburgh; Mr. Furneaux Jordan, Birmingham; Mr. Beal, London; Dr. O'Connor, London; Dr. Hoffmeister, Cowes; Mr. Whiteford; Dr. Stephenson, Bradninch; Mr. Higgins, London; Dr. R. L. Johnson, London; Dr. Tripe, London; Dr. Cock, Ross; Dr. Thursfield, Shrewsbury; Dr. Bantock, London; Mr. Dolan, Halifax; Dr. Alexander, Bradford; Dr. Ross, Belfast; Mr. Vacher, Birkenhead; Mr. Barnish, Wigan; Mr. Tube, Cheltenham; Mr. King, Leeds; Mr. Davis, Hereford; Mr. Smyth; Mrs. Graying, Forest-hill; Mr. Saunder; Messrs. Clark and Co., York; Mr. T aylor; Dr. Tibbits, Bradford; Dr. Caskie, London; Dr. Budd, Clifton; Dr. Drummond, Newcastle-on-Tyne; Mr. Rendle, London; Mr. Greenway, Plymouth; Dr. Bakewell, Hokitika, N.Z.; Dr. Moore, Dublin; Mr. Davies, Shorborne; Mr. Stewart, Barnsley; Dr. Lush, Fyfield; Dr. Allen Duke, Folkestone; Mr. L. Tait, Birmingham; Mr. Wilkinson; Mr. Prideaux, Wellington; H. J. F.; Lesus; E. B. D.; A Constant Subscriber; Fides; Surgeon-Major; Lecturer; Juvenal; &c. &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Miller, Newport; Mrs. Bromhead, Lincoln; Dr. Clark, Folkestone; Dr. Edge, Manchester; Mr. Gulliver, London; Dr. Waters, Liverpool; Mr. Harris, Hackney; Mr. Atkinson, Farnham; Miss Rimington, Nottingham; Mr. Spowencer, Gainsborough; Mr. Stelfox, Darwen; Mr. Collingwood, Corby; Mr. Tomson, Luton; Messrs. Sharp and Co., Newcastle-on-Tyne; Mr. M'Bain, Otago, New Zealand; Dr. Dickson, Buxton; Messrs. Maw, Son, and Thompson; A. B., Canterbury; A., Sheffield; E. J.; A. A.; Superintendent, Croydon; Medicus, Middlesbrough; Alpha, London; Alpha, Darwin; M. A., Claughton; W. S. S.; R. E., Llandover; &c.

Science, Missouri Republican, Ormskirck Advertiser, Wigan Observer, Gatlard's Medical Journal, La Escuela de Medici, Brighton Herald, Ramgiltkei Advocate, Freeman's Journal, Monmouthshire Beacon, &c., have been received.

Lawrie, Dr. E., gunshot wound of the median nerve, 576

Lawson, Mr. G., Diseases and Injuries of the Eye (review), 701
Leather straps & bandages, 360

LECTURES, ETC.

BARNES, Dr. R.:—
Clinical Lectures on the Diseases of Women.
Lecture III., 121
Lecture IV., 923

BRADBURY, Dr. J. B.:
Address in Medicine (Abstract of the), delivered at the Meeting of the British Medical Association on Aug. 11th, 1880, 245

BROWNE, Dr. J. C.:
Address (Abstract of an), delivered at the Opening of the Section of Psychology, at the Meeting of the British Medical Association at Cambridge, August, 1880, 232

BUTLIN, Mr. H. T.:
Lectures on the Relations of Sarcoma to Carcinoma. Delivered at the Royal College of Surgeons in June, 1880.
Lecture I., 204, 330
Lecture II., 437, 523
Lecture III., 801, 839

BUZZARD, Dr. T.:
Clinical Lecture (Substance of a) on Cases of Acute Atrophic Paralysis in Infants and Adults (Acute Anterior Polio-myelitis).
Lecture I., 925
Lecture II., 1007

CAVAYE, Dr. J.:
Introductory Lecture (Abstract of) on the Education of the General Practitioner. Delivered at St. George's Hospital, Oct. 1st, 1880, 571

CHARTERS, Dr. M.:
Clinical Retrospect of a Half-year's Hospital Work, 161, 490

COWELL, Mr. G.:
Clinical Lecture on a Case of Strangulated Hernia. Delivered at Westminster Hospital, 882

DUNCAN, Dr. J. M.:
An Address on the Treatment of Puerperal Fever. Delivered before the Midland Medical Society at Birmingham, October 20th, 1880, 683, 721

FOSTER, Dr. M.:
Address in Physiology delivered at the Meeting of the British Medical Association at Cambridge, on Aug. 13th, 1880, 287

GAMGEE, Mr. S.:
Clinical Lecture on the Essentials of Wound Treatment, 367

GEE, Dr. S.:
Clinical Lecture on Large Heads in Children. Delivered in St. Bartholomew's Hospital, June 4th, 1880, 449

GOULD, Mr. A. P.:
Clinical Lecture (part of a) on the Radical Cure of Varicocele by the Galvanic Ecraseur. Delivered at the Westminster Hospital, July 3rd, 1880, 83

GREENFIELD, Dr. W. S.:
Lectures on some recent Investigations into the Pathology of Infective and Contagious Diseases. Delivered in connexion with the Brown Institution, at the University of London, December, 1879.
Lecture III., 41

The Brown Lectures. Further Investigations on Anthrax and Allied Diseases in Man and Animals. Delivered at the University of London on Dec. 13th, 1880
Lecture I., 965

HOLMES, Mr. T.:
Address in Surgery, delivered at the Meeting of the British Medical Association at Cambridge, 251

HUMPHREY, Dr. G. M.:
Presidential Address, delivered at the Meeting of the British Medical Association, at Cambridge, on Aug. 10th, 1880, 243

JACKSON, Dr. J. H.:
Lecture (part of a) on Auditory Vertigo. Delivered at the National Hospital for the Epileptic and Paralysed, 525

JOHNSON, Dr. G.:
An Address delivered at King's College after the Distribution of Scholarships and Prizes at the Opening of the Winter Session, 569

MACGOWEN, Dr. W.:
Clinical Lecture on the Results of Antiseptic Osteotomy for Genu Valgum, Varum, and other Osseous Deformities of the Lower Limb, 450

NORTON, A. T.:
Clinical Lecture on Carcinoma of the Sigmoid Flexure. Delivered at St. Mary's Hospital, 966

PAGET, Sir J.:
An Address on Elemental Pathology. Delivered in the Pathological Section of the British Medical Association, 603, 645

PLAYFAIR, Dr. W. S.:
Address delivered at the Opening of the Section of Obstetric Medicine, at the Meeting of the British Medical Association at Cambridge, August, 1880, 295

POLLOCK, Mr. G.:
Observations on the Treatment of Hemorrhoids by "Crushing," 1

POORE, Dr. G. V.:
Lectures on the Physical Examination of the Mouth and Throat. Delivered to the Junior Class of Clinical Medicine, University College.
Lecture IV., 81
Lecture V., 327
Lecture VI., 369

POWELL, Dr. R. D.:
Clinical Lectures on some Cases of Heart Disease. Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.
Lecture III., 123

SANDERSON, Dr. J. B.:
Introductory Address on the Motives and Methods of Medical Study. Delivered at the commencement of the Winter Session of University College, 565

SOUTHEY, Dr. R.:
Clinical Lecture on the Interdiagnosis of Insensibility from various Causes, 881

STURGES, Dr. O.:
Lecture (Abstract of a) on the Design and Scope of Lectures on the Practice of Medicine, introductory to that Course given at Westminster Hospital, 607

TEEVAN, Mr. W. F.:
Lectures on the Treatment of Stricture of the Urethra, Enlarged Prostate, and Stone in the Bladder, with special reference to recent Progress. Delivered at the Medical Society of London, February, 1880.
Lecture III.—Part II., 162

TURNER, Mr. W.:
Address at the Opening of the Anatomical Department in the New Buildings of the University of Edinburgh, 724, 759

YEO, Dr. I. B.:
Clinical Lecture (Abstract of a) on a Case in which numerous Gall-stones were discharged through a Fistulous Opening in the Abdominal Wall. Delivered in King's College Hospital, May 11th, 1880, 203

Ledwich School of Medicine, introductory lecture at, 792

Lee, Dr. B., the infection of phthisis, 793

Leeds, "Russian typhus" in, 71

Lees, Dr. K., the dose and value of calcium sulphide in, 435

Leg and foot, congenital deformity of the, 813

Leicester, infant diarrhoea in, 363; summer diarrhoea in, 632

Leith, sewer ventilation at, 993

Lemonade, poisonous, 72

Lens, dislocation of the into the vitreous, 763

Leprosy, 779; case of true Eastern, 692; fish-eating a, 747, 837, 873, 922

Lesser's canal, the, 273

Leucæmia, amoeboid movements of the colourless blood-corpuscles in, 769

Lewins, Dr. R., Life and Mind on the Basis of Modern Medicine (review), 500, 509

Lewisham, a self-supporting dispensary at, 563

Life and Mind on the Basis of Modern Medicine (review), 599

Limerick, water-supply of, 515

Lindsay, Dr. W. L., obituary notice of, 915

Ling, Mr. C. A. S., lithotomy, 72

Linton, Sir W., obituary notice of, 639

Lister, Professor, 906; recent honours to, 984

Lister's method, an example of the value of, in a phthisical patient, 935

Listerism, debate on, 978, 987

Litholapaxy, 52, 694; in Bombay, 49

Litho-nephrotomy, case of, 6

Lithotomy, 234, 720

Lithotrite, accident to a, 553; at one sitting, 52, 691

Littlejohn, Dr. H. D., on the compulsory intimation of infectious diseases in Edinburgh, 749

Liver, peritoneal adhesions in tropical abscess of the, death, 341; cancer of, invading stomach, 981

Lloyd, Mr. H. J., Barmouth as a health-resort, 719

Local authority, a confused, 952

Government Board, report of the, 630, 672, 743; reports of medical inspectors of the, 110, 186, 864, 1036

Locomotor ataxy arthropathies, 51; eye symptoms in, 968, 932

Locum tenens, 415; justice to one's, 284; an uncourteous, 813

Lodging-houses, 476

London, water-supply of, 267, 392, 512, 552, 711, 788, 885, 909; fog in, 614; fever hospital, 904; University, 236, 281, 321, 362, 833, 916, 959

Longevity in England, 322

Longmore, Mr. T., introductory address by, at the Army Medical School, 581

Lower Thames Valley sewerage, 589, 827, 991

Lucas, Mr. B. C., Guy's Hospital, 765; on cross-legged paralysis, 1009; on rickets, 1017

Lucas-Championnière, Dr. J., Chirurgie Antiseptique: Principes, Modes d'Application, et Résultats du Pansement de Lister (review), 15

Lunacy Law Amendment Bill, 19

law question, the, and private asylums, 902

reports for 1879, 465

Lunatic asylums, 949

Lund, Mr. E., on Removal of the Entire Tongue (review), 621

Luong, puzzling case of cancer of the, 259; primary cancer of, 753; recurrent epithelioma in it; on the diagnosis of cavity in the, 973

Lush, Dr. W. N., treatment of scarlet fever by warm baths, 284

Lymphadenoma, notes of a case of, 377; case of, operation, recovery, 616

Lyons hospital, the, 857

Lyster, Dr. C. E., treatment of stricture, 622

MacCormac, Mr. W., Antiseptic Surgery, Address delivered at St. Thomas's Hospital (review), 15

Macdonald, Dr. J., the late, 241

Mr. C. R., placenta prævia and rupture of the uterus, 601

Macdowall, Mr. C., hypodermic injections of morphia in cholera, 638

Macewen, Dr. W., on the results of antiseptic osteotomy for genu valgum, varum, and other osseous deformities of the lower limb, 450; Osteotomy, with an Inquiry into the Etiology and Pathology of Knock-knee, Bow-leg, and other Osseous Deformities of the Lower Limbs (review), 817

McGann, Mr. T. J., remarks on stricture of the urethra in connexion with internal urethrotomy, 728

Mackellar, Dr. E. D., typhoid in India, 557

Mackenzie, Dr. D. J., treatment of phthisis, 953

Dr. G. H., the infection of phthisis, and its bearings upon treatment, 870

Maclean, Dr. T. J., on the anti-malarial action of the chinchona compounds, 165, 213, 295

MacLaren, Dr. R., the aspirator as an aid to diagnosis in cases of obstruction of the bowel, with description of an enterotomy tube, 762

Maclean, Dr. T. E., the blood in anæmia, 285

Dr. W. C., army medical report for 1873, 115

Monamara, Mr. E., treatment of stricture, 516, 622

M. Oscar, Dr. J., the Upper Engadine, St. Moritz, 324

Madden, Dr. E. M., "homœopathic practitioners," 757

Madras, fever statistics in, 799

Mahaffy, Rev. J. P., A History of Classical Greek Literature (review), 131

Mamma, colloid cancer of, 52

Manchester, vaccination on prosecution in, 69; hospital etiquette at, 470; "sums" and air, 515; Hospital Sunday Fund, 990

Royal Infirmary, 182

Manders, Mr. H., treatment of stricture, 556

Manitoba, the climate of, 983

Margate, sanitary condition of, 500

Marsh, Mr. H., the treatment of chronic inflammatory affections of the joints in childhood, with especial reference to excision, 167

Mr. W. J., suprapubic puncture of the bladder, 483

Martindale, Mr. W., Chian turpentine, 553

Martin's Atlas of Obstetrics and Gynecology (review), 175

Maylebone, the Medical officership of, 742

Mason v. Peck, 355

Massachusetts State Board of Health, 515

Masterman, Mr. G. F., the use of the hot vaginal douche, 159; effects of an exclusive meat diet, 662

Mater Misericordie Hospital, introductory lecture at, 791

Maternal impressions, 654

Mayer, Dr. J. B., neuralgia, 38

May, Mr. E., diphtheria and its treatment, 638; "wanted a diagnosis," given a suggestion, 921; bronchitis complicated with diarrhoea, 963

Mr. E. H., a case of litho-nephrotomy, 6

Mayo, the epidemic of fever in, 71, 110, 393

Meat diet, exclusive, effects of, 521, 562

Meath Hospital, introductory lecture at, 791

Meath nerve, gunshot wound of the, 575

Medical and surgical statistics, 780

assistants, and their religious persuasion, 680

charity, an ancient, 241

certificates, a county court judge on, 77

education, 903, 912, 954, 936, 994

ethics, 241

indulgences, 943

legislation, 989, 703

Medical magistrates, 76
 — officers of health, reports of, 26, 68, 147, 187, 226, 271, 309, 350, 390, 474, 511, 552, 630, 668, 709, 743, 787, 828, 8-5, 9-8, 951, 991, 1036
 — qualifications, the *Newcastle Chronicle* on, 142

 — Register, erasure of names from the, 201; accuracy of, 707
 — schools, changes in the, 410

MEDICAL SOCIETIES.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—Serous cysts; Cases of neuralgia dependent upon non-erupted teeth, 941
CAMBRIDGE MEDICAL SOCIETY.—Menorrhagia in old age through emotional disturbance; Diabetes from same cause; Therapeutic uses of hyoscyamine; Secondary pelvic tumour; Gummata in brain, liver, and testicles; Bovine tuberculosis in man, 54
CLINICAL SOCIETY.—Severe laceration of face; Ataxy in several members of a family; Sclerotomy for eyeball tension; Elephantiasis of leg treated by elastic bandaging; Case of epilepsy treated by trephining, 618—Cross-legged progression, owing to double hip ankylosis; Acute intestinal obstruction by hernia through mesentery of a Meckel's diverticulum; Nephro-lithotomy, 696—Stretching of facial nerve for the relief of spasm of facial muscles; Myxoedema; Persistent erythema, 814—Hydro-encephalocoele; Varicocele with small testicles; Ulceration of the colon, with hypertrophy and dilatation; Right hemiplegia after scarlatina, 894—Retarded signs in pneumonia; Left hemiplegia with aphasia; Radical cure of web-fingers; Removal of villous growth from bladder, 978
EPIDEMIOLOGICAL SOCIETY.—The continued fevers of India and tropical climates, 53—Sir Joseph Fayer's inaugural address, 773
MEDICAL OFFICERS OF HEALTH SOCIETY.—Inaugural address by the president, 658—The action of disinfectants on sewage and the living organisms contained therein, 855
MEDICAL SOCIETY OF LONDON.—Recovery from symptoms of organic brain disease, 657—Paralysis of lower limbs, following pelvic abscess, on profuse loss of blood after abortion, 699—Pleurisy with effusion; Aneurism of ascending aorta; Atrophy of the stomach, 734—Tumour of cerebellum; Mitral stenosis; Reduplication of cardiac sounds, 772—Recurrent epistaxis; Diagnosis and treatment of whooping-cough; Pauper lunacy laws and medical relief, 816—Hydrocele; Apoplexy from embolism; Acute hip disease following osteitis of femur; Accident to a lithotrite, 853—Perforation of stomach in hydrochloric acid poisoning; Cerebral embolism; Treatment of genu valgum, 896—Clinical features of pleural effusions, 940—Gastric ulcer; Cancer of liver invading stomach; Intestinal obstruction from contraction of ileal mucous membrane, 980
MIDLAND MEDICAL SOCIETY.—Inaugural meeting, 700
OBSTETRICAL SOCIETY.—Exhibition of specimens; Extra-uterine fecundation; Sixty-seven cases of uterine distortion or displacement, 14—Congenital dislocation of both hips; Rotatory action of the forceps, 772—Pyometra; Hydrocephalus; Anencephalous monster; Maternal impressions; Chorea in Pregnancy; Absence of the vagina; Congenital abnormality of the uterus, 854
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Optic neuritis; Nodular growth on iris; Primary intraocular hemorrhage, 775—Opacities in vitreous humour following injury; Retinal hemorrhages and degeneration in scurvy and in idiopathic anemia; Congenital absence of eyeball; Paralysis of cranial nerves with hemiplegia; Peritomy; Eye symptoms in locomotor ataxy, 981
PATHOLOGICAL SOCIETY.—Dilatation of central canal of spinal cord; Procephalus; Fibroid tumour of uterus; Myeloid tumour of tibia; Fatty tumour of larynx; Fatty tumour of scalp; Acute necrosis of tibia; Osteitis of femur; Paralysis of cranial nerves in congenital syphilis; Fracture of coracoid process, 656—Multiple exostoses; Sebaceous tumour of leg; Cancer of lung; Blood in diabetes; Tumour of knee-joint; Recurrent epithelioma in lung; Mucous polypus of umbilicus; Ataxic arthropathy; Hemiatrophia facialis; Telostitis; Morphea, 732—Congenital deformity of leg and foot; Congenital malformation of heart; Rickets; Cranio-tabes, 813—Osteitis deformans; Adjoined discussion on rickets, 937, 1015
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—

Basic cavity of the lung treated by paracentesis, 12—Aneurism of the external carotid, in which, after failure of the ligature of the common carotid, the old operation was performed successfully; Abscess in the neck, causing destruction of a large portion of the carotid artery, jugular vein, and pneumogastric nerve, 695—Amoeboid movements of the colourless blood-corpuscles in leucæmia; Nature and treatment of genu valgum, 769—Artificial respiration in new-born children, 851—Hydatids of the liver treated by abdominal section and drainage; Hyperpyrexia after "Listerian ovariectomy," 976
WOLVERHAMPTON DISTRICT MEDICAL SOCIETY.—Inaugural Meeting, 620

Medical study, on the motives and methods of, 565
 — trial at the Antipodes, 283
 — Medicine, the address in, 245
 — Medicines, adulterated, 160
 — Medicine-bottle bags, 777
 — Medico-Psychological Association, 237
 — Medulla oblongata, the arciform fibres of the, 142
 — Membrana tympani, perforation of, from ascaris lumbricoides, 653
 — Menorrhagia in old age through emotional disturbance, 54
 — Meredith, Mr. W. A., extra-peritoneal ovariectomy, 297
 — Meryon, Dr. E., obituary notice of, 838
 — Metropolitan Asylums Board, 909
 — Drinking Fountains Association, 226
 — Free Hospital, 35
 — police court, a, 588
 — Mickle's General Paralysis of the Insane (review), 942
 — Micro-filaria, 25
 — Mid-Cheshire, libel on the medical officer of health of, 226
 — Middlesex Hospital, 586
 — Midland Medical Society, 700
 — Midwifery, antiseptic, 497, 641, 719, 831
 — Midwives, death certification by, 226
 — Military prisons, our, 666
 — Milk, from phthisical cows, danger of, 228; adulteration of, 513; infected, and diphtheria, 879; and water, 631
 — Milk-supply of the metropolis, 711
 — Miller, Dr. J. D., "running" impulse in epilepsy, 323
 — Miller's Elements of Chemistry (review), 301
 — Mills, Mr. J., on watching the pulse during the administration of chloroform, 92
 — Miñe, Dr. I. K., coated pills, 523
 — Mines, accidents in, 197

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

ALNWICK INFIRMARY.—Extensive laceration of both forearms with fracture of the bones; recovery, 937
ALTRINGHAM HOSPITAL.—Stone in the bladder; lithotripsy, with evacuation; cure, 541
ASHBURTON AND BUCKPASTLEIGH COTTAGE HOSPITAL.—Plastic operation for contracting cicatrix, 617—Chronic effusion into bursa patellæ and bursa ligamentæ patellæ; communication between the two bursæ, 813
BIRKENHEAD BOROUGH HOSPITAL.—Traumatic cardiac hernia, 261
BIRMINGHAM QUEEN'S HOSPITAL.—Compound comminuted fracture of the humerus; Listerism; recovery, 768—Wound over the patella; Listerism; recovery, ib.
BURRA BURRA HOSPITAL, S. AUSTRALIA.—Double empyema treated by excision and aspiration; recovery, 617
CHARING-CROSS HOSPITAL.—Rupture of axillary artery during reduction of luxation of the humerus; diffuse traumatic aneurism; amputation at the shoulder-joint; death; remarks, 260
CROYDON GENERAL HOSPITAL.—Ovariectomy; recovery, 373
DUNDEE ROYAL INFIRMARY.—Three cases illustrating the difficulties of recognising internal cancer, 540
EDINBURGH WESTERN DISPENSARY.—Cases from the throat department; remarks, 340
FULHAM SMALL-POX HOSPITAL.—Two fatal cases of hemorrhagic variola; necropsies, 850
GLASGOW ROYAL INFIRMARY.—Introduction of a tracheal tube through the mouth for the administration of chloroform during an operation for the removal of epithelioma from the mouth and fauces, 813
GREAT NORTHERN HOSPITAL.—Inward compound dislocation at the ankle-joint, with fracture, 935; fistula, ib.
GUY'S HOSPITAL.—Ruptured hæmatocoele of the tunica vaginalis; incision; castration; recovery; remarks, 299—Encysted hæmatocoele; incision; recovery, ib.

KASHMIR MISSION HOSPITAL.—Dislocations of the hip-joint, 655—Obstruction of the bowels caused by large worms; Amussat's operation; death, 893
KENDAL COTTAGE HOSPITAL.—Congenital atresia of the vagina, 10
KING'S COLLEGE HOSPITAL.—Left-sided epileptic hemiplegia and aphasia; recovery, 730
LEEDS GENERAL INFIRMARY.—Cases of injury to the eye, 131—Aphasia following injury to the head, 851
LINCOLN COUNTY HOSPITAL.—Case of cancer of the rectum; colotomy; recovery, 92—Cases illustrating use of plaster-of-Paris bandage in hip-disease, ib.
LIVERPOOL NORTHERN HOSPITAL.—Disease of rectum (syphilitic); stricture; colotomy; death after six weeks, from exhaustion, 731
LONDON HOSPITAL.—An unusual case of lameness; operation; cure, 340—Ovarian dysmenorrhæa, with retroflexion of the uterus; symptoms demonstrated to be unconnected with the retroflexion, 892
LIVERPOOL ROYAL INFIRMARY.—Case of Diabetes presenting peculiar features, 172
LUXOR HOUSE OF HEALTH.—Large tumour in the right temporal region; removal; recovery; remarks, 173
MANCHESTER ROYAL INFIRMARY.—Case of locomotor ataxy with arthropathies, 51—Aneurism of the left superficial femoral artery; ligature of the external iliac; hæmaturia; incision into the sac; secondary hæmorrhage; gangrene of toes; recovery, 300—Chronic synovitis of knee-joint; aspiration of joint, 378—Acute suppuration of knee-joint; aspiration, ib.—Apparent typhoid fever; cerebral hæmorrhage; death, 459—Profuse intra-cranial hæmorrhage; intense headache; vomiting; delirium; absence of hemiplegia; coma; glycosuria; death, 460
MIDDLESEX HOSPITAL.—Tubercular peritonitis in an adult; necropsy; remarks, 498—Case of lymphadenoma; operation; recovery, 616
MORETON-IN-MARSH COTTAGE HOSPITAL.—Ovariectomy; recovery, 216
NEWARK HOSPITAL.—A case of quassia poisoning, 260—Opium poisoning; recovery, 654—Fracture of inner condyle of right humerus; perfect union, 769
NEWCASTLE-ON-TYNE INFIRMARY.—Cerebellar tumour; necropsy, 893
ST. GEORGE'S HOSPITAL.—Dislocation of the femur into the sciatic notch in a man seventy-two years old; reduction seventy-two days after the injury, 130—Epithelioma of the rectum removed after a new plan without injuring the sphincter ani; recovery, 540—Soft cataract in one eye, and a high degree of myopia in the other, both recent, 768—Dislocation of the lens into the vitreous, ib.
ST. MARY'S HOSPITAL.—Two cases of antiseptic surgery, 51
ST. PANCRAS WORKHOUSE INFIRMARY.—A successful case of ovariectomy, 130
ST. THOMAS'S HOSPITAL.—Surgical cases, 171—Tracheotomy in a child under six months old; recovery, 849
SAMARITAN FREE HOSPITAL.—Cases of ruptured perineum, 458
SEAMEN'S HOSPITAL, GREENWICH.—Two cases of obscure nervous disorder, 693
SHANGHAI GENERAL HOSPITAL.—Peritoneal adhesions in tropical abscess of the liver; death; remarks, 341
SHEFFIELD GENERAL INFIRMARY.—Contused wound of knee-joint; suppurative; recovery, 379—Knee-joint disease; excision; recovery, ib.—Compound comminuted fracture of thigh; recovery, 498
SOUTH STAFFORDSHIRE HOSPITAL.—Scirrhus of the breast in the male, 216—Scirrhus of the perineum, with cancerous infiltration of the subperitoneal glands, 975
STAMFORD AND RUTLAND INFIRMARY.—Lithotripsy, with rapid evacuation (Bigelow's method); two sittings; cure, 52
SUSSEX COUNTY HOSPITAL.—Lithotripsy at one sitting, 694
TOTARA DISTRICT HOSPITAL, ROSS, NEW ZEALAND.—Hydatids of liver; ascites; multiple abscesses; death, 11—Hydatids of right lung; obstinate dry cough; formation of white fibrinous clot in heart; death, ib.
TOXTETH PARK WORKHOUSE INFIRMARY.—Hæmorrhage into the spinal cord, 694—Aneurism of the arch of the aorta, ib.
TYRONE COUNTY INFIRMARY.—Strangulated femoral hernia; operation without opening the sac; rapid recovery, 499
UNIVERSITY COLLEGE HOSPITAL.—Repeated expectoration of hydatid membrane; no physical signs of hydatid disease either in the chest or abdomen, 10—Case of cancer of the uterus treated by Chian turpentine, 92—Paralysis of the left vocal cord, 654—Extensive epithelioma of the lower jaw and floor of the mouth; removal; satisfactory state two

- years after, 812—Amputation of both upper limbs; recovery, 936—Rupture of central portion of extensor tendon of right thigh, just above patella, the lateral expansions from the vasti muscles being intact and the knee-joint unopened, 937
- VICTORIA DOCK DISTRICT DISPENSARY.—Malformation of the heart and abscess of the brain; unusual contents, 768
- WANDSWORTH INFIRMARY.—Case of purpura hemorrhagica; death, necropsy, 1014
- WEST LONDON HOSPITAL.—Hæmorrhagic diathesis; hæmorrhage from the mouth; death, 377
- WESTMINSTER HOSPITAL.—Pylephlebitis; rigors simulating ague, 215—Progressive wasting; rigors; caseation of spleen, *ib.*—Galactocoele; incision; cure, 850—*Iliac* abscess treated antiseptically; cure, 974
- WEST NORFOLK AND LYNN HOSPITAL.—Colloid cancer of mamma, 52
- Mississippi, fever on the, 790
- Mitral stenosis, 772
- Molet, Dr. F. W., abstract of introductory address delivered at the opening of the winter session of the School of Medicine, Surgeon's Hall, Edinburgh, 729
- Money *v.* alcohol, 921
- Moorhouse, Mr. W., obituary notice of, 639
- More, Dr. J., case of traumatic tetanus, 652
- Morpheo, the, 826
- Murphy, 734
- Morris, Mr. H., treatment of stricture, 556; Guy's Hospital, 631; on Chian turpentine and its uselessness in cancer, 844, 886
- Mortuaries, 654; private, 759
- Mouth and throat, on the physical examination of the, 31, 327, 369
- Mullingar, sanitary condition of, 394
- Municipal morality, 27
- Municipality of London Bill, 27
